

z/OS Communications Server
3.2

IP Configuration Reference

Note:

Before using this information and the product it supports, be sure to read the general information under [“Notices” on page 1371](#).

This edition applies to 3.1 of z/OS® (5655-ZOS), and to subsequent releases and modifications until otherwise indicated in new editions.

Figures.....	xix
Tables.....	xxiii
About this document.....	xxix
Who should read this document.....	xxix
How this document is organized.....	xxix
How to use this document.....	xxix
How to provide feedback to IBM.....	xxix
Conventions and terminology that are used in this information.....	xxix
How to read a syntax diagram.....	xxxi
Prerequisite and related information.....	xxxiv
Summary of changes for IP Configuration Reference.....	xxxix
Summary of changes for z/OS 3.2.....	xxxix
Changes made in z/OS Communications Server 3.1.....	xxxix
Chapter 1. Configuration data sets and files.....	1
TCP/IP configuration data sets.....	1
Chapter 2. TCP/IP profile (PROFILE.TCPIP) and configuration statements.....	11
Summary of TCP/IP address space configuration statements.....	11
PROFILE.TCPIP search order.....	14
Statement syntax for configuration statements.....	14
AUTOLOG statement.....	16
BEGINROUTES statement.....	19
BSDROUTINGPARMS statement.....	27
DEFADDRTABLE statement.....	30
DELETE statement.....	32
Summary of DEVICE and LINK statements.....	35
Overview of DEVICE and LINK statements.....	35
Recovering from device failures.....	36
Missing interrupt handler factors.....	37
DEVICE and LINK statements relationship to VTAM configuration.....	37
Modifying DEVICE and LINK statements.....	37
Monitoring network links (DEVICE and LINK statements).....	39
DEVICE and LINK - CTC devices statement.....	39
DEVICE and LINK - MPCIPA HiperSockets devices statement.....	41
DEVICE and LINK - MPCPTP devices statement.....	44
DEVICE and LINK - VIRTUAL devices statement.....	47
GLOBALCONFIG statement.....	49
HOME statement.....	76
INCLUDE statement.....	80
Summary of INTERFACE statements.....	80
Restrictions on IPv6 addresses configured in the TCP/IP profile.....	83
Steps for modifying INTERFACE statements.....	83
Monitoring network interfaces (INTERFACE statements).....	84
INTERFACE - IPAQENET OSA-Express QDIO interfaces statement.....	84
INTERFACE - EQENET Network Express Enhanced QDIO interfaces statement.....	98

INTERFACE - IPAQIDIO HiperSockets interfaces statement.....	105
INTERFACE - VIRTUAL interfaces statement.....	109
INTERFACE - EQENET6 Network Express Enhanced QDIO interfaces statement.....	110
INTERFACE - IPAQENET6 OSA-Express QDIO interfaces statement.....	116
INTERFACE - IPAQIDIO6 HiperSockets interfaces statement.....	131
INTERFACE - LOOPBACK6 interface statement.....	136
INTERFACE - MPCPTP6 interfaces statement.....	137
INTERFACE - VIRTUAL6 interfaces statement.....	141
IPCONFIG statement.....	143
IPCONFIG6 statement.....	156
IPSEC statement.....	166
ITRACE statement.....	179
NETACCESS statement.....	181
NETMONITOR statement.....	185
OSAENTA statement.....	193
PKTTRACE statement.....	200
PORT statement.....	207
PORTRANGE statement.....	216
PRIMARYINTERFACE statement.....	220
SACONFIG statement.....	221
SMFCONFIG statement.....	224
SMFPARMS statement.....	232
SOMAXCONN statement.....	233
SRCIP statement.....	233
START statement.....	242
STOP statement.....	243
TCPCONFIG statement.....	244
UDPCONFIG statement.....	251
VIPADYNAMIC statement summary.....	253
VIPADYNAMIC - VIPADefine statement.....	254
VIPADYNAMIC - VIPABACKUP statement.....	258
VIPADYNAMIC - VIPADELETE statement.....	261
VIPADYNAMIC - VIPADISTRIBUTE statement.....	261
VIPADYNAMIC - VIPARANGE statement.....	276
VIPADYNAMIC - VIPAROUTE statement.....	280
Chapter 3. TCP/IP cataloged procedure (TCPIPROC).....	283
Specifying TCP/IP address space parameters.....	283
Example of a TCP/IP cataloged procedure.....	284
Using output data sets.....	285
Chapter 4. Protocol number and port assignments.....	287
Port assignments.....	287
PROFILE.TCPIP port assignments.....	288
/etc/services and ETC.SERVICES port assignments.....	290
Chapter 5. Resolver setup and TCPIP.DATA configuration statements.....	295
Resolver setup statements.....	295
Resolver setup statement information and syntax conventions.....	297
CACHE NOCACHE statements.....	299
CACHEREORDER NOCACHEREORDER statements.....	299
CACHESIZE statement.....	300
COMMONSEARCH/NOCOMMONSEARCH statement.....	301
DEFAULTIPNODES statement.....	301
DEFAULTTCPIPDATA statement.....	302
GLOBALIPNODES statement.....	303
GLOBALTCPIPDATA statement.....	304

MAXNEGTTTL statement.....	306
MAXTTTL statement.....	306
UNRESPONSIVETHRESHOLD statement.....	307
; and # statements.....	309
Configuration statements in TCPIP.DATA.....	310
system_name considerations.....	311
Dynamically changing TCPIP.DATA statements.....	312
Determining which TCPIP.DATA statements are being used.....	313
Syntax conventions for TCPIP.DATA configuration statements.....	314
ALWAYSWHO statement.....	314
DATASETPREFIX statement.....	315
DOMAIN statement.....	316
DOMAINORIGIN statement.....	316
HOSTNAME statement.....	317
LOADDBCSTABLES statement.....	318
LOOKUP statement.....	319
MESSAGECASE statement.....	320
NAMESERVER statement.....	321
NOCACHE statement.....	321
NOCACHEREORDER statement.....	322
NSINTERADDR statement.....	323
NSPORTADDR statement.....	325
OPTIONS statement.....	326
RESOLVERTIMEOUT statement.....	328
RESOLVERUDPRETRIES statement.....	329
RESOLVEVIA statement.....	331
SEARCH statement.....	332
SOCKDEBUG statement.....	333
SOCKNOTESTSTOR statement.....	333
SOCKTESTSTOR statement.....	334
SORTLIST statement.....	334
TCPIPJOBNAME statement.....	336
TCPIPUSERID statement.....	337
TRACE RESOLVER statement.....	337
TRACE SOCKET statement.....	338
; and # statements.....	338
Sample TCPIP.DATA data set (TCPDATA).....	339
Resolver configuration statements for IBM z/OS Container Platform environments.....	343
Syntax conventions for resolver configuration statements for IBM z/OS Container Platform environments.....	343
Dynamically changing resolver configuration statements for IBM z/OS Container Platform environments.....	344
NAMESERVER statement.....	344
OPTIONS NDOTS statement.....	346
SEARCH statement.....	347
TCPIPJOBNAME statement.....	348
HOSTS statement.....	349
Chapter 6. z/OS Load Balancing Advisor and Load Balancing Agent.....	351
General syntax rules for z/OS Load Balancing Advisor.....	351
Starting the z/OS Load Balancing Advisor.....	351
Load Balancing Advisor sample start procedure.....	352
Load Balancing Advisor configuration file statements.....	352
agent_connection_port statement.....	354
agent_id_list statement.....	354
debug_level statement.....	355
lb_connection_v4 statement.....	356

lb_connection_v6 statement.....	356
lb_id_list statement.....	357
port_list statement.....	358
sysplex_group_name statement.....	360
update_interval statement.....	361
wlm statement.....	361
Starting the z/OS Load Balancing Agent.....	362
z/OS Load Balancing Agent sample start procedure.....	363
z/OS Load Balancing Agent configuration file statements.....	363
advisor_id statement.....	364
debug_level statement.....	364
host_connection statement.....	365
sysplex_group_name statement.....	366
Chapter 7. Automated domain name registration.....	367
General configuration rules for automated domain name registration.....	367
Starting the automated domain name registration application.....	368
EZBADNRS sample start procedure for automated domain name registration application.....	368
Automated domain name registration application configuration file	369
arm_element_suffix statement.....	371
debug_level statement.....	372
dns statement.....	373
gwm statement.....	375
host_group statement.....	376
ipaddrlist statement.....	378
key statement.....	378
server_group statement.....	379
uuid statement.....	380
Chapter 8. IKE daemon.....	383
Starting the IKED using z/OS UNIX.....	383
IKE cataloged procedure.....	383
IKE environment variables.....	384
IKE daemon configuration file statements.....	386
IkeConfig statement.....	387
NssStackConfig statement.....	399
IKE daemon configuration file sample.....	401
Chapter 9. Network security services server.....	405
Starting Network security services server using z/OS UNIX.....	405
Network security services server cataloged procedure.....	405
Network security services server environment variables.....	406
Network security services server configuration file statements.....	408
NSS server configuration file sample.....	408
IPSecDisciplineConfig statement.....	410
NssConfig statement.....	413
Chapter 10. Defense Manager daemon.....	417
Starting the DMD using z/OS UNIX (optional).....	417
The Defense Manager daemon cataloged procedure (optional).....	417
DMD environment variables.....	418
DMD configuration file statements.....	420
DmConfig statement.....	420
DmStackConfig statement.....	422
DMD configuration file sample.....	424
Chapter 11. OMPROUTE.....	429

Starting OMPROUTE using z/OS UNIX (optional).....	429
OMPROUTE cataloged procedure (optional).....	429
OMPROUTE parameters.....	430
OMPROUTE environment variables.....	431
OMPROUTE configuration file statements.....	433
INCLUDE statement.....	433
OSPF configuration statements.....	434
RIP configuration statements.....	450
IPv6 OSPF configuration statements.....	461
IPv6 RIP configuration statements.....	472
Common configuration statements for RIP and OSPF.....	480
Interfaces supported by OMPROUTE.....	489

Chapter 12. TN3270E Telnet server..... 493

Telnet profile statements overview.....	493
TELNETGLOBALS statements.....	493
TELNETPARMS statements.....	493
PARMSGROUP statements.....	493
BEGINVTAM block.....	493
INCLUDE statement.....	493
Telnet statement syntax.....	494
Telnet parameter statements in the Telnet profile.....	496
Rules for Telnet parameter statements.....	499
BINARYLINEMODE statement.....	500
CHECKCLIENTCONN statement.....	500
CODEPAGE statement.....	501
CONNTYPE statement.....	502
DBCSTRACE statement.....	502
DBCSTRANSFORM statement.....	503
DEBUG statement.....	503
DISABLESGA statement.....	505
DROPASSOCPRINTER statement.....	505
EXPRESSLOGON statement.....	506
EXPRESSLOGONMFA statement.....	506
FORMAT statement.....	507
FULLDATATRACE statement.....	507
INACTIVE statement.....	508
INCLUDE statement.....	508
KEEPINACTIVE statement.....	509
KEEPLU statement.....	509
LIMITQ statement.....	510
LUSESSIONPEND statement.....	510
MAXRECEIVE statement.....	511
MAXREQSESS statement.....	511
MAXRUCHAIN statement.....	512
MAXTCPSSENDQ statement.....	512
MAXVTAMSENDQ statement.....	513
MSG07 statement.....	513
NACUSERID statement.....	514
OLDSOLICITOR statement.....	514
PASSWORDPHRASE statement.....	515
PORT and TTLSPORT statements.....	515
PROFILEINACTIVE statement.....	516
PRTINACTIVE statement.....	516
REFRESHMSG10 statement.....	517
SCANINTERVAL and TIMEMARK statements.....	517
SEQUENTIALLU statement.....	518

SGA statement.....	518
SHAREACB statement.....	519
SIMCLIENTLU statement.....	519
SINGLEATTN statement.....	520
SMFINIT and SMFTERM statements.....	520
SMFPROFILE statement.....	521
SNAEXT statement.....	522
TCPIPJOBNAME statement.....	523
TELNETDEVICE statement.....	523
TESTMODE statement.....	525
TIMEMARK statement.....	525
TKOGENLU, TKOGENLURECON, and NOTKO statements.....	525
TKOSPECLU, TKOSPECLURECON, and NOTKO statements.....	527
TN3270E statement.....	528
TNSACONFIG statement.....	529
UNLOCKKEYBOARD statement.....	531
XCFGROUP statement.....	531
Telnet mapping statements in the Telnet profile.....	533
Rules for LU name specification.....	535
Client identifier types and definitions.....	536
Rules for client identifier specification.....	537
Rules for host name specification.....	537
ALLOWAPPL statement.....	538
DEFAULTAPPL statement.....	539
DEFAULTLUS or SDEFAULTLUS statement.....	540
DEFAULTLUSSPEC or SDEFAULTLUSSPEC statement.....	541
DEFAULTPRT or SDEFAULTPRT statement.....	542
DEFAULTPRTSPEC or SDEFAULTPRTSPEC statement.....	543
DESTIPGROUP statement.....	544
HNGROUP statement.....	544
INTERPTCP statement.....	545
IPGROUP statement.....	546
LINEMODEAPPL statement.....	547
LINKGROUP statement.....	548
LUGROUP or SLUGROUP statement.....	548
LUMAP statement.....	550
MONITORGROUP statement.....	551
MONITORMAP statement.....	553
PARMSGROUP statement.....	553
PARMSMAP statement.....	554
PORT statement.....	554
PRTDEFAULTAPPL statement.....	555
PRTGROUP or SPRTGROUP statement.....	556
PRTMAP statement.....	557
RESTRICTAPPL statement.....	558
USERGROUP statement.....	560
USSTCP statement.....	561
Telnet USS table setup.....	561
General usage rules for Telnet USS macroinstructions.....	562
USSCMD macroinstruction.....	562
USSMSG macroinstruction.....	563
USSPARM macroinstruction.....	567
USSTAB macroinstruction.....	569
USSEND macroinstruction.....	570
Telnet INTERPRET table setup.....	570
General usage rules for Telnet INTERPRET macroinstructions.....	570
INTAB macroinstruction.....	570
LOGCHAR macroinstruction.....	571

ENDINTAB macroinstruction.....	574
Telnet LU exit setup.....	575
Telnet LU exit setup operation.....	575
Requirements for LU exit routines.....	577
LU exit routine parameter list.....	578
Chapter 13. EXPRESS LOGON using DCAS.....	579
Starting Digital Certificate Access Server.....	579
Digital Certificate Access Server (DCAS) sample procedure (EZADCASP).....	581
Digital Certificate Access Server (DCAS) environment variables.....	581
Digital Certificate Access Server (DCAS) configuration file keywords and parameters.....	582
CLIENTAUTH.....	582
IPADDR.....	583
PORT.....	583
SERVERTYPE.....	583
TCPIP.....	585
TLSMECHANISM.....	585
Steps for setting up RACF for Digital Certificate Access Server (DCAS).....	585
Chapter 14. File Transfer Protocol.....	587
FTP server cataloged procedure (FTPD).....	587
FTP server cataloged procedure (FTPD) parameters.....	589
FTP server user exits.....	590
Sample server user exits.....	591
The FTCHKCMD user exit.....	591
The FTPOSTPR user exit.....	593
The FTCHKIP user exit.....	595
The FTCHKPWD user exit.....	596
The FTCHKJES user exit.....	598
The FTP server SMF user exit.....	599
FTP client user exits.....	599
Sample client user exits.....	601
The EZAFCCMD user exit.....	601
The EZAFCREP user exit.....	607
Using both EZAFCCMD and EZAFCREP user exits.....	609
FTP configuration statements in FTP.DATA.....	609
Summary of FTP client and server configuration statements.....	610
FTP.DATA data set statements.....	628
ACCESSERRORMSG (FTP server) statement.....	628
ADMINEMAILADDRESS (FTP server) statement.....	629
ANONYMOUS (FTP server) statement.....	630
ANONYMOUSFILEACCESS (FTP server) statement.....	632
ANONYMOUSFILETYPEJES (FTP server) statement.....	633
ANONYMOUSFILETYPESEQ (FTP server) statement.....	633
ANONYMOUSFILETYPESQL (FTP server) statement.....	634
ANONYMOUSFTPLOGGING (FTP server) statement.....	635
ANONYMOUSHFSDIRMODE (FTP server) statement.....	636
ANONYMOUSHFSFILEMODE (FTP server) statement.....	637
ANONYMOUSHFSINFO (FTP server) statement.....	637
ANONYMOUSLEVEL (FTP server) statement.....	638
ANONYMOUSLOGINMSG (FTP server) statement.....	640
ANONYMOUSMVSINFO (FTP server) statement.....	642
APPLNAME (FTP server) statement.....	643
ASATRANS (FTP client and server) statement.....	643
AUTOMOUNT (FTP client and server) statement.....	644
AUTORECALL (FTP client and server) statement.....	644
AUTOTAPEMOUNT (FTP client and server) statement.....	645

BANNER (FTP server) statement.....	646
BLKSIZE (FTP client and server) statement.....	647
BUFNO (FTP client and server) statement.....	648
CCONNTIME (FTP client) statement.....	648
CCTRANS (FTP client) statement.....	649
CCXLATE (FTP server) statement.....	649
CHKCONFIDENCE statement (FTP client and server) statement.....	650
CHKPTFLUSH (FTP client) statement.....	652
CHKPTINT (FTP client and server) statement.....	652
CHKPTPREFIX (FTP client) statement.....	654
CIPHERSUITE (FTP client) statement.....	655
CLIENTERRCODES (FTP client) statement.....	657
CLIENTEXIT (FTP client) statement.....	657
CONDDISP (FTP client and server) statement.....	658
CTRL_TLS_SESSTCKTS (FTP server) statement.....	659
CTRLCONN (FTP client and server) statement.....	660
DATACLASS (FTP client and server) statement.....	661
DATACETIME (FTP client) statement.....	663
DATAKEEPAIVE (FTP client and server) statement.....	664
DATATIMEOUT (FTP server) statement.....	664
DB2 (FTP client and server) statement.....	665
DB2PLAN (FTP client and server) statement.....	666
DBSUB (FTP client and server) statement.....	666
DCBDSN (FTP client and server) statement.....	667
DCONNTIME (FTP client and server) statement.....	668
DEBUG (FTP client and server) statement.....	668
DEBUGONSITE (FTP server) statement.....	670
DEST (FTP server) statement.....	671
DIRECTORY (FTP client and server) statement.....	671
DIRECTORYMODE (FTP client and server) statement.....	672
DSNTYPE (FTP client and server) statement.....	673
DSWAITTIME (FTP client and server) statement.....	674
DSWAITTIMEREPLY (FTP server) statement.....	675
DUMP (FTP client and server) statement.....	677
DUMPPON SITE (FTP server) statement.....	678
EATTR (FTP client and server) statement.....	678
EMAILADDRCHECK (FTP server) statement.....	679
ENCODING (FTP client and server) statement.....	680
EPSV4 (FTP client) statement.....	681
EXTENSIONS (FTP client and server) statement.....	682
FIFOIOTIME (FTP client and server) statement.....	684
FIFOOPEN TIME (FTP client and server) statement.....	685
FILETYPE (FTP client and server) statement.....	686
FTPKEEPAIVE (FTP client and server) statement.....	687
FTPLOGGING (FTP server) statement.....	688
FWFRIENDLY (FTP client) statement.....	689
HFSINFO (FTP server) statement.....	690
INACTIVE (FTP Server) statement.....	691
INACTTIME (FTP client) statement.....	691
ISPFSTATS (FTP client and server) statement.....	692
JESENTRYLIMIT (FTP server) statement.....	693
JESGETBYDSN (FTP server) statement.....	693
JESINTERFACELEVEL (FTP server) statement.....	694
JESLRECL (FTP server) statement.....	696
JESPUTGETTO (FTP server) statement.....	697
JESRECFM (FTP server) statement.....	697
KEYRING (FTP client) statement.....	698
LISTLEVEL (FTP server) statement.....	699

LISTSUBDIR (FTP client and server) statement.....	700
LOGCLIENTERR (FTP client) statement.....	702
LOGINMSG (FTP server) statement.....	703
LRECL (FTP client and server) statement.....	704
MBDATACONN (FTP client and server) statement.....	705
MBREQUIRELASTEOL (FTP client and server) statement.....	706
MSENDEOL statement (FTP client and server) statement.....	707
MGMTCLASS (FTP client and server) statement.....	708
MIGRATEVOL (FTP client and server) statement.....	709
MVSINFO (FTP server) statement.....	710
MVSURLKEY (FTP server) statement.....	710
MYOPENTIME (FTP client) statement.....	711
NETRCLEVEL (FTP client) statement.....	712
NONSWAPD (FTP server) statement.....	712
PASSIVEDATACONN (FTP server) statement.....	713
PASSIVEDATAPORTS (FTP server) statement.....	714
PASSIVEIGNOREADDR (FTP client) statement.....	714
PASSIVEONLY (FTP client) statement.....	715
PASSPHRASE (FTP server) statement.....	716
PDSTYPE (FTP client and server) statement.....	717
PORTCOMMAND (FTP server) statement.....	718
PORTCOMMANDIPADDR (FTP server) statement.....	718
PORTCOMMANDPORT (FTP server) statement.....	719
PORTOFENTRY4 (FTP server) statement.....	720
PRIMARY (FTP client and server) statement.....	720
PROGRESS (FTP client) statement.....	721
QUOTESOVERRIDE (FTP client and server) statement.....	722
RDW (FTP client and server) statement.....	723
RECFM (FTP client and server) statement.....	723
REMOVEINBEOF (FTP client and server) statement.....	725
REPLY226 (FTP server) statement.....	726
REPLYSECURITYLEVEL (FTP server) statement.....	727
RESTGET (FTP client) statement.....	728
RESTPUT (FTP server) statement.....	728
RETPD (FTP client and server) statement.....	729
SBDATACONN (FTP client and server) statement.....	731
SSENDEOL statement (FTP client and server) statement.....	732
SBSUB (FTP client and server) statement.....	733
SBSUBCHAR (FTP client and server) statement.....	734
SBTRANS (FTP client) statement.....	735
SECONDARY (FTP client and server) statement.....	735
SECURE_CTRLCONN (FTP client and server) statement.....	736
SECURE_DATACONN (FTP client and server) statement.....	738
SECURE_FTP (FTP client and server) statement.....	739
SECURE_HOSTNAME (FTP client) statement.....	741
SECUREIMPLICITZOS (FTP client and server) statement.....	741
SECURE_LOGIN (FTP server) statement.....	743
SECURE_MECHANISM (FTP client) statement.....	744
SECURE_PASSWORD (FTP server) statement.....	745
SECURE_PASSWORD_KERBEROS (FTP server) statement.....	746
SECURE_PBSZ (FTP client and server) statement.....	748
SECURE_SESSION_REUSE (FTP client and server) statement.....	749
SEQNUMSUPPORT (FTP client) statement.....	751
SMF (FTP server) statement.....	752
SMFAPPE (FTP server) statement.....	754
SMFDCFG (FTP server) statement.....	755
SMFDEL (FTP server) statement.....	756
SMFEXIT (FTP server) statement.....	757

SMFJES (FTP server) statement.....	758
SMFLOGN (FTP server) statement.....	759
SMFREN (FTP server) statement.....	760
SMFRETR (FTP server) statement.....	761
SMFSQL (FTP server) statement.....	762
SMFSTOR (FTP server) statement.....	763
SOCKSCONFIGFILE (FTP client) statement.....	764
SPACETYPE (FTP client and server) statement.....	765
SPREAD (FTP client and server) statement.....	766
SQLCOL (FTP client and server) statement.....	767
SSLV3 (FTP client connection) statement.....	768
STARTDIRECTORY (FTP server) statement.....	768
STORCLASS (FTP client and server) statement.....	769
SUPPRESSIGNOREWARNINGS (FTP client and server) statement.....	770
TAPEREADSTREAM (FTP server) statement.....	771
TLSCERTCROSSCHECK (FTP client and server) statement.....	771
TLSMECHANISM (FTP client and server) statement.....	772
TLSPORT (FTP client and server) statement.....	773
TLSRFCLEVEL (FTP client and server) statement.....	774
TLSTIMEOUT (FTP client) statement.....	775
TLSV1 (FTP client) statement.....	776
TRACE (FTP client and server) statement.....	776
TRACEAPI (FTP client) statement.....	777
TRAILINGBLANKS (FTP client and server) statement.....	778
TRUNCATE (FTP client and server) statement.....	778
UCOUNT (FTP client and server) statement.....	779
UCSHOSTCS (FTP client and server) statement.....	780
UCSSUB (FTP client and server) statement.....	780
UCSTRUNC (FTP client and server) statement.....	781
UMASK (FTP client and server) statement.....	781
UNICODEFILESYSTEMBOM (FTP client and server) statement.....	782
UNITNAME (FTP client and server) statement.....	784
UNIXFILETYPE (FTP client and server) statement.....	784
VCOUNT (FTP client and server) statement.....	786
VERIFYUSER (FTP server) statement.....	787
VOLUME (FTP client and server) statement.....	788
WRAPRECORD (FTP client and server) statement.....	789
WRTAPEFASTIO (FTP client and server) statement.....	790
XLATE (FTP server) statement.....	791
FTP server environment variables.....	791
SOCKS configuration statements in SOCKSCONFIGFILE.....	792
DIRECT statement.....	792
SOCKD statement.....	793

Chapter 15. Syslog daemon.....795

Syslog daemon files.....	795
Starting syslogd with a cataloged procedure.....	795
Starting syslogd from the UNIX shell.....	797
Syslogd environment variables.....	800
Syslogd configuration statements.....	802
Global syslogd configuration statements.....	802
Syslogd rule configuration statement.....	805
Syslogd browser tool.....	815
Providing library access.....	816
Adding the syslogd browser to the ISPF primary option menu.....	816

Chapter 16. Policy Agent and policy applications..... 819

Policy configuration files.....	819
Policy Agent configuration files overview.....	819
Policy Agent configuration statements overview.....	820
General syntax rules for Policy Agent.....	820
Policy Agent general configuration file statements.....	837
AutoMonitorApps statement.....	845
AutoMonitorParms statement.....	849
ClientConnection statement.....	850
Codepage statement.....	851
CommonIDSConfig statement.....	852
CommonIPSecConfig statement.....	853
CommonRoutingConfig statement.....	853
CommonTTLSType statement.....	854
DynamicConfigPolicyLoad statement.....	855
IDSConfig statement.....	861
IPSecConfig statement.....	862
LogLevel statement.....	863
PolicyPerfMonitorForSDR statement.....	864
PolicyPerformanceCollection statement.....	867
PolicyServer statement.....	869
QOSConfig statement.....	872
ReadFromDirectory statement.....	873
RoutingConfig statement.....	879
ServerConnection statement.....	880
ServicesConnection statement.....	886
SetSubnetPrioToMask statement.....	890
TcpImage and PEPInstance statement.....	892
TTLSType statement.....	894
ZERTConfig statement.....	895
AT-TLS policy statements.....	896
TTLSCipherParms statement.....	897
TTLSType statement.....	902
TTLSTypeAdvancedParms statement.....	905
TTLSTypeEnvironmentAction statement.....	914
TTLSTypeEnvironmentAdvancedParms statement.....	917
TTLSTypeGroupAction statement.....	929
TTLSTypeGroupAdvancedParms statement.....	932
TTLSTypeGskAdvancedParms statement.....	933
TTLSTypeGskHttpCdpParms statement.....	940
TTLSTypeGskLdapParms statement.....	941
TTLSTypeGskOcspParms statement.....	944
TTLSTypeKeyringParms statement.....	951
TTLSTypeRule statement.....	952
TTLSTypeSignatureParms statement.....	956

About this document

This document contains reference material such as statement syntax, options, keywords, and descriptions for z/OS Communications Server. It also provides detailed information for the statements used to configure address spaces, servers, and applications. For detailed information about configuration-related tasks, see [z/OS Communications Server: IP Configuration Guide](#).

Use this document to perform the following tasks:

- Configure z/OS Communications Server
- Customize and administer z/OS Communications Server

The information in this document includes descriptions of support for both IPv4 and IPv6 networking protocols. Unless explicitly noted, descriptions of IP protocol support concern IPv4. IPv6 support is qualified within the text.

This document refers to Communications Server data sets by their default SMP/E distribution library name. Your installation might, however, have different names for these data sets where allowed by SMP/E, your installation personnel, or administration staff. For instance, this document refers to samples in SEZAINST library as simply in SEZAINST. Your installation might choose a data set name of SYS1.SEZAINST, CS390.SEZAINST or other high level qualifiers for the data set name.

Who should read this document

This document is intended for programmers and system administrators who are familiar with TCP/IP, MVS, z/OS, UNIX, and the Time Sharing Option Extensions (TSO/E).

How this document is organized

This document contains the following information:

- TCP/IP system information, including TCP/IP concepts and overview information about the TCP/IP system.
- Server application information, including descriptions of server applications, including cataloged procedures, and configuration statements.
- Appendixes provide additional details for the base and application information.
- “Notices” on page 1371 contains notices and trademarks used in this information.
- “Bibliography” on page 1375 contains descriptions of the information in the z/OS Communications Server library.

How to use this document

To use this document, you should be familiar with z/OS TCP/IP Services and the TCP/IP suite of protocols.

How to provide feedback to IBM

We welcome any feedback that you have, including comments on the clarity, accuracy, or completeness of the information. See, [How to send feedback to IBM®](#) for additional information.

Conventions and terminology that are used in this information

Commands in this information that can be used in both TSO and z/OS UNIX environments use the following conventions:

- When describing how to use the command in a TSO environment, the command is presented in uppercase (for example, NETSTAT).
- When describing how to use the command in a z/OS UNIX environment, the command is presented in bold lowercase (for example, **netstat**).
- When referring to the command in a general way in text, the command is presented with an initial capital letter (for example, Netstat).

All the exit routines described in this information are *installation-wide exit routines*. The installation-wide exit routines also called installation-wide exits, exit routines, and exits throughout this information.

The TPF logon manager, although included with VTAM®, is an application program; therefore, the logon manager is documented separately from VTAM.

Samples used in this information might not be updated for each release. Evaluate a sample carefully before applying it to your system.

z/OS no longer supports mounting HFS data sets (The POSIX style file system). Instead, a z/OS File System (zFS) can be implemented. The term hierarchical file system, abbreviated as HFS, is defined as a data structure that has a hierarchical nature with directories and files. References to hierarchical file systems or HFS might still be in use in z/OS Communications Server publications.

Network Express and Open Systems Adapter-Express (OSA-Express) terminology:

- The Network Express feature is introduced with the IBM z17 processor family. The Network Express feature is the next generation of Open Systems Adapter (OSA) technology. The term OSA (Open Systems Adapter) is carried forward with Network Express. The IBM z17 processor supports both the Network Express and the OSA-Express^{7S} features. In this information, when a general reference is made to OSA that applies to all these features, then the term OSA is used, and the acronym will appear in italics. This formatting style and guideline for usage for the term OSA is used throughout this document. When a distinction is necessary, then the specific feature name is used such as the Network Express feature
- The Network Express feature is defined as channel (CHPID) type OSH (Open System Adapter for Hybrid networks) that might operate in either 10 GbE or 25 GbE link speed. When this term is used in this information, the processing being described applies to either link speed. If processing is applicable to only one link speed, the full terminology, for instance, IBM 25 GbE Network Express will be used.
- Network Express is defined with new system architecture called Enhanced Queued Direct I/O (EQDIO). In this information there are many references to QDIO or OSA/QDIO. When the reference applies to both QDIO and EQDIO the reference just indicates OSA. When the reference is specific to the QDIO or EQDIO architecture, then the specific architecture is referenced, for example, OSA/QDIO or OSA/EQDIO. Some OSA references also use or include the channel type for OSA such as OSD (QDIO). When the reference applies to both features, then the term OSA is used. When a distinction is necessary then the specific channel or architecture type is used, OSD/QDIO or OSH/EQDIO.

Shared Memory Communications over Remote Direct Memory Access (SMC-R) terminology

- *RoCE*, which is a generic term representing IBM® 10 GbE RoCE Express, IBM 10 GbE RoCE Express2, IBM 25 GbE RoCE Express2, IBM 10 GbE RoCE Express3, IBM 25 GbE RoCE Express3, IBM 10 GbE Network Express and IBM 25 GbE Network Express feature capabilities. When this term is used in this information, the processing being described applies to all of these features. If processing is applicable to only one feature, the full terminology, for instance, Network Express will be used.
- RoCE Express2, which is a generic term representing an IBM RoCE Express2 feature that might operate in either 10 GbE or 25 GbE link speed. When this term is used in this information, the processing being described applies to either link speed. If processing applies to only one link speed, the full terminology, for instance, IBM 25 GbE RoCE Express2 will be used.
- RoCE Express3, which is a generic term representing an IBM RoCE Express3 feature that might operate in either 10 GbE or 25 GbE link speed. When this term is used in this information, the processing being described applies to either link speed. If processing applies to only one link speed, the full terminology, for instance, IBM 25 GbE RoCE Express3 will be used.
- Network Express, which is a generic term representing an Network Express feature that might operate in either 10 GbE or 25 GbE link speed. When this term is used in this information, the processing

being described applies to either link speed. If processing is applicable to only one link speed, the full terminology, for instance, IBM 25 GbE Network Express will be used. When configured with a CHPID type of NETH, the Network Express feature may operate as an RDMA network interface card.

- RDMA network interface card (RNIC), which is used to refer to the IBM 10 GbE RoCE Express, IBM 10 GbE RoCE Express2, IBM 25 GbE RoCE Express2, IBM 10 GbE RoCE Express3, or IBM 25 GbE RoCE Express3, IBM 10 GbE Network Express or IBM 25 GbE Network Express feature.
- Shared RoCE environment, which means that the *ROCE* feature can be used concurrently, or shared, by multiple operating system instances. The feature is considered to operate in a shared RoCE environment even if you use it with a single operating system instance.

Clarification of notes

Information traditionally qualified as Notes is further qualified as follows:

Attention

Indicate the possibility of damage

Guideline

Customary way to perform a procedure

Note

Supplemental detail

Rule

Something you must do; limitations on your actions

Restriction

Indicates certain conditions are not supported; limitations on a product or facility

Requirement

Dependencies, prerequisites

Result

Indicates the outcome

Tip

Offers shortcuts or alternative ways of performing an action; a hint

How to read a syntax diagram

This syntax information applies to all commands and statements that do not have their own syntax described elsewhere.

The syntax diagram shows you how to specify a command so that the operating system can correctly interpret what you type. Read the syntax diagram from left to right and from top to bottom, following the horizontal line (the main path).

Symbols and punctuation

The following symbols are used in syntax diagrams:

Symbol

Description

➤

Marks the beginning of the command syntax.

➤

Indicates that the command syntax is continued.

|

Marks the beginning and end of a fragment or part of the command syntax.

➤

Marks the end of the command syntax.

You must include all punctuation such as colons, semicolons, commas, quotation marks, and minus signs that are shown in the syntax diagram.

Commands

Commands that can be used in both TSO and z/OS UNIX environments use the following conventions in syntax diagrams:

- When describing how to use the command in a TSO environment, the command is presented in uppercase (for example, NETSTAT).
- When describing how to use the command in a z/OS UNIX environment, the command is presented in bold lowercase (for example, netstat).

Parameters

The following types of parameters are used in syntax diagrams.

Required

Required parameters are displayed on the main path.

Optional

Optional parameters are displayed below the main path.

Default

Default parameters are displayed above the main path.

Parameters are classified as keywords or variables. For the TSO and MVS console commands, the keywords are not case sensitive. You can code them in uppercase or lowercase. If the keyword appears in the syntax diagram in both uppercase and lowercase, the uppercase portion is the abbreviation for the keyword (for example, OPERand).

For the z/OS UNIX commands, the keywords must be entered in the case indicated in the syntax diagram.

Variables are italicized, appear in lowercase letters, and represent names or values you supply. For example, a data set is a variable.

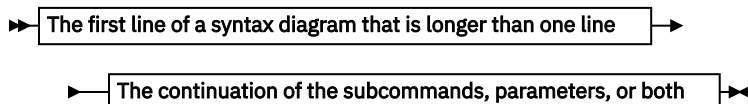

Syntax examples

In the following example, the P`U`t subcommand is a keyword. The required variable parameter is *local_file*, and the optional variable parameter is *foreign_file*. Replace the variable parameters with your own values.

Longer than one line

If a diagram is longer than one line, the first line ends with a single arrowhead and the second line begins with a single arrowhead.

Required operands

Required operands and values appear on the main path line. You must code required operands and values.

➤ REQUIRED_OPERAND ➤

Optional values

Optional operands and values appear below the main path line. You do not have to code optional operands and values.

Selecting more than one operand

An arrow returning to the left above a group of operands or values means more than one can be selected, or a single one can be repeated.

Nonalphanumeric characters

If a diagram shows a character that is not alphanumeric (such as parentheses, periods, commas, and equal signs), you must code the character as part of the syntax. In this example, you must code OPERAND=(001,0.001).

➤ OPERAND — = — (— 001 — , — 0.001 —) ➤

Blank spaces in syntax diagrams

If a diagram shows a blank space, you must code the blank space as part of the syntax. In this example, you must code OPERAND=(001 FIXED).

➤ OPERAND — = — (— 001 — — FIXED —) ➤

Default operands

Default operands and values appear above the main path line. TCP/IP uses the default if you omit the operand entirely.

Variables

A word in all lowercase italics is a *variable*. Where you see a variable in the syntax, you must replace it with one of its allowable names or values, as defined in the text.

➤ variable ➤

Syntax fragments

Some diagrams contain syntax fragments, which serve to break up diagrams that are too long, too complex, or too repetitious. Syntax fragment names are in mixed case and are shown in the diagram and in the heading of the fragment. The fragment is placed below the main diagram.

➤ Syntax fragment ➤

Syntax fragment

➤ 1ST_OPERAND — , — 2ND_OPERAND — , — 3RD_OPERAND ➤

Prerequisite and related information

z/OS Communications Server function is described in the z/OS Communications Server library. Descriptions of those documents are listed in [“Bibliography”](#) on page 1375, in the back of this document.

Required information

Before using this product, you should be familiar with TCP/IP, VTAM, MVS, and UNIX System Services.

Softcopy information

Softcopy publications are available in the following collection.

Titles	Description
<i>IBM Z Redbooks</i>	The IBM Z [®] subject areas range from e-business application development and enablement to hardware, networking, Linux [®] , solutions, security, parallel sysplex, and many others. For more information about the Redbooks [®] publications, see http://www.redbooks.ibm.com/ and http://www.ibm.com/systems/z/os/zos/zfavorites/ .

Other documents

This information explains how z/OS references information in other documents.

When possible, this information uses cross-document links that go directly to the topic in reference using shortened versions of the document title. For complete titles and order numbers of the documents for all products that are part of z/OS, see [z/OS Information Roadmap \(SA23-2299\)](#). The Roadmap describes what level of documents are supplied with each release of z/OS Communications Server, and also describes each z/OS publication.

To find the complete z/OS library, visit the [z/OS library](#) in [IBM Documentation](#) (<https://www.ibm.com/docs/en/zos>).

Relevant RFCs are listed in an appendix of the IP documents. Architectural specifications for the SNA protocol are listed in an appendix of the SNA documents.

The following table lists documents that might be helpful to readers.

Title	Number
<i>DNS and BIND</i> , Fifth Edition, O'Reilly Media, 2006	ISBN 13: 978-0596100575
<i>Routing in the Internet</i> , Second Edition, Christian Huitema (Prentice Hall 1999)	ISBN 13: 978-0130226471

Title	Number
<i>sendmail</i> , Fourth Edition, Bryan Costales, Claus Assmann, George Jansen, and Gregory Shapiro, O'Reilly Media, 2007	ISBN 13: 978-0596510299
<i>SNA Formats</i>	GA27-3136
<i>TCP/IP Illustrated, Volume 1: The Protocols</i> , W. Richard Stevens, Addison-Wesley Professional, 1994	ISBN 13: 978-0201633467
<i>TCP/IP Illustrated, Volume 2: The Implementation</i> , Gary R. Wright and W. Richard Stevens, Addison-Wesley Professional, 1995	ISBN 13: 978-0201633542
<i>TCP/IP Illustrated, Volume 3: TCP for Transactions, HTTP, NNTP, and the UNIX Domain Protocols</i> , W. Richard Stevens, Addison-Wesley Professional, 1996	ISBN 13: 978-0201634952
<i>TCP/IP Tutorial and Technical Overview</i>	GG24-3376
<i>Understanding LDAP</i>	SG24-4986
z/OS Cryptographic Services System SSL Programming	SC14-7495
z/OS IBM Tivoli Directory Server Administration and Use for z/OS	SC23-6788
z/OS JES2 Initialization and Tuning Guide	SA32-0991
z/OS Problem Management	SC23-6844

The z/OS Basic Skills Information Center

The z/OS Basic Skills Information Center is a web-based information resource intended to help users learn the basic concepts of z/OS, the operating system that runs most of the IBM mainframe computers in use today. The Information Center is designed to introduce a new generation of Information Technology professionals to basic concepts and help them prepare for a career as a z/OS professional, such as a z/OS systems programmer.

Specifically, the z/OS Basic Skills Information Center is intended to achieve the following objectives:

- Provide basic education and information about z/OS without charge
- Shorten the time it takes for people to become productive on the mainframe
- Make it easier for new people to learn z/OS

To access the z/OS Basic Skills Information Center, open your web browser to the following website, which is available to all users (no login required): <https://www.ibm.com/support/knowledgecenter/zosbasics/com.ibm.zos.zbasics/homepage.html?cp=zosbasics>

Summary of changes for IP Configuration Reference

This document contains terminology, maintenance, and editorial changes, including changes to improve consistency and retrievability. Technical changes or additions to the text and illustrations for the current edition are indicated by a vertical line to the left of the change.

Summary of changes for z/OS 3.2

The following content is new, changed, or no longer included in z/OS 3.2.

New

The following content is new.

September 2025 release

- For TLS updates, see:
 - [“TLSV1 \(FTP client\) statement”](#) on page 776
 - [“TTLSSignatureParms statement”](#) on page 956
 - [“TTLSGskAdvancedParms statement”](#) on page 933
 - [“General syntax rules for Policy Agent”](#) on page 820

Changed

The following content is changed.

September 2025 release

- [“AT-TLS policy statements”](#) on page 896
- [“IpFilterRule statement”](#) on page 1004
- [“IpTimeCondition statement”](#) on page 1128
- [“TTLSCONNECTIONAdvancedParms statement”](#) on page 905
- [“TTLSEnvironmentAdvancedParms statement”](#) on page 917
- [“Summary of FTP client and server configuration statements”](#) on page 610

Deleted

The following content is deleted.

September 2025 release

- None.

Changes made in z/OS Communications Server 3.1

The following content is new, changed, or no longer included in z/OS 3.1.

New information

May 2025 refresh

- Added support for the IBM Network Express feature. This new feature provides the latest Enhanced QDIO (EQDIO) architecture for reliable high-speed ethernet transport as well as providing RoCEv2 to support optimized TCP connectivity using RDMA technology with Shared Memory Communications (SMC-R). For more information, see [“INTERFACE - EQENET Network Express Enhanced QDIO interfaces”](#)

[statement](#)” on page 98 and [“INTERFACE - EQENET6 Network Express Enhanced QDIO interfaces statement”](#) on page 110.

March 2025 refresh

- Added details about the AuthEntity parameter for the TargetServer configuration file statement. For more information, see [“TargetServer statement”](#) on page 1264. This function is available with APAR PH61015 on z/OS 3.1 and V2R5.

December 2024 refresh

- z/OS Communications Server is enhanced to enable the configuration and use of multiple VIPARANGE ZCONTAINER statements for use by containers started with z/OS Container Platform (zOSCP). This function is available on z/OS 3.1 and V2R5 with APAR PH63940. For more information, see [“VIPADYNAMIC - VIPARANGE statement”](#) on page 276.

March 2024 refresh

- Network support for IBM z/OS Container Platform, see the following topics:
 - [“Resolver configuration statements for IBM z/OS Container Platform environments”](#) on page 343
 - [“Dynamically changing resolver configuration statements for IBM z/OS Container Platform environments”](#) on page 344
 - [“NAMESERVER statement”](#) on page 344
 - [“OPTIONS NDOTS statement”](#) on page 346
 - [“SEARCH statement”](#) on page 347
 - [“TCPIPJOBNAME statement”](#) on page 348
 - [“HOSTS statement”](#) on page 349

September 2023 release

- z/OS UNIX syslogd support for secure logging over TCP, see the following topics:
 - [“File destinations for syslogd”](#) on page 811
 - [“Remote destinations for syslogd”](#) on page 814

Changed information

June 2025 Refresh

- Updated IPADDR parameter description in [“INTERFACE - EQENET Network Express Enhanced QDIO interfaces statement”](#) on page 98
- Updated devnum parameter > Tips in [“INTERFACE - IPAQENET OSA-Express QDIO interfaces statement”](#) on page 84
- Updated devnum parameter > Tips in [“INTERFACE - IPAQENET6 OSA-Express QDIO interfaces statement”](#) on page 116
- Maximum number of ports allowed in the VIPADYNAMIC – VIPADISTRIBUTE statement is enhanced to 256. For more information, see [“VIPADYNAMIC - VIPADISTRIBUTE statement”](#) on page 261.

May 2025 refresh

- Updated the following topics with OSA and RoCE, wherever applicable:
 - [“Summary of TCP/IP address space configuration statements”](#) on page 11
 - [“GLOBALCONFIG statement”](#) on page 49
 - [“Summary of INTERFACE statements”](#) on page 80
 - [“INTERFACE - IPAQENET OSA-Express QDIO interfaces statement”](#) on page 84
 - [“INTERFACE - IPAQENET6 OSA-Express QDIO interfaces statement”](#) on page 116
 - [“IPCONFIG statement”](#) on page 143

- [“PolicyAction statement” on page 1083](#)
- [“PolicyRule statement” on page 1090](#)
- Added another restriction to the Target Server Statement parameters. See [“TargetServer statement” on page 1264](#).

July 2024 refresh

- Sysplex Distributor support for IBM z/OS Control Plane Appliances, see the following topics:
 - [“VIPADYNAMIC - VIPADISTRIBUTE statement” on page 261](#)
 - [“SRCIP statement” on page 233](#)

March 2024 refresh

- Network support for IBM z/OS Container Platform, see the following topics:
 - [“CACHE NOCACHE statements” on page 299](#)
 - [“COMMONSEARCH/NOCOMMONSEARCH statement” on page 301](#)
 - [“GLOBALIPNODES statement” on page 303](#)
 - [“GLOBALTCPIPDATA statement” on page 304](#)
 - [“COMMONSEARCH/NOCOMMONSEARCH statement” on page 301](#)
 - [“VIPADYNAMIC - VIPARANGE statement” on page 276](#)
 - [“PORT statement” on page 207](#)
 - [“PORTRANGE statement” on page 216](#)
- zERT support for z/OS 3.2 OpenSSH upgrade, see the following topics:
 - [“ZERTKeyExchange statement” on page 1110](#)
 - [“General syntax rules for Policy Agent” on page 820](#)

December 2023 refresh

- ReplaceSubjectAtSign configuration option for CSSMTP, see [“Options statement” on page 1258](#).

September 2023 release

- Persistent Pause Support for Sysplex Distributor DVIPAs, see [“VIPADYNAMIC - VIPADISTRIBUTE statement” on page 261](#).
- AT-TLS currency with System SSL, see the following topics:
 - [“TTLSGskAdvancedParms statement” on page 933](#)
 - [“TTLSEnvironmentAdvancedParms statement” on page 917](#)
 - [“TTLSConnectionAdvancedParms statement” on page 905](#)
 - [“General syntax rules for Policy Agent” on page 820](#)
- AT-TLS support for x25519 and x448 key exchange for TLSv1.2, see the following topic:
 - [“TTLSSignatureParms statement” on page 956](#)
- Communications Server support for RoCE Express3, see the following topic:
 - [“GLOBALCONFIG statement” on page 49](#)
- FTP server JES access control, see [“FILETYPE \(FTP client and server\) statement” on page 686](#).
- OSA-Express Enhanced Inbound Blocking (EIB), see the following topics:
 - [“INTERFACE - IPAQENET OSA-Express QDIO interfaces statement” on page 84](#)
 - [“INTERFACE - IPAQENET6 OSA-Express QDIO interfaces statement” on page 116](#)
- Removal of OSA DEVICE/LINK/Home Configuration Support, see the following topics:
 - [“Summary of TCP/IP address space configuration statements” on page 11](#)
 - [“Missing interrupt handler factors” on page 37](#)

- [“INTERFACE - IPAQENET OSA-Express QDIO interfaces statement” on page 84](#)
- [“INTERFACE - IPAQENET6 OSA-Express QDIO interfaces statement” on page 116](#)
- [“IPCONFIG statement” on page 143](#)
- [“PKTTRACE statement” on page 200](#)
- [“Overview of DEVICE and LINK statements” on page 35](#)
- [“Interfaces supported by OMPROUTE” on page 489](#)
- z/OS UNIX syslogd support for secure logging over TCP, see the following topic:
 - [“PORT statement” on page 207](#)
 - [“Starting syslogd with a cataloged procedure” on page 795](#)
 - [“Starting syslogd from the UNIX shell” on page 797](#)
 - [“Syslogd environment variables” on page 800](#)
 - [“Parameters” on page 806](#)
 - [“Usage notes for syslogd” on page 807](#)
 - [“Supported destinations for syslogd” on page 811](#)

Deleted information

- Removal of OSA DEVICE/LINK/Home Configuration Support, the following topics have been deleted:
 - *ARPAGE statement*
 - *DEVICE and LINK - LAN Channel Station and OSA devices statement*
 - *DEVICE and LINK - MPCIPA OSA-Express QDIO devices statement*
 - *TRANSLATE statement*

Chapter 1. Configuration data sets and files

This topic contains information about the configuration data sets and files that are used by the TCP/IP servers and functions.

This information refers to Communications Server data sets by their default SMP/E distribution library name. However, your installation might have different names for these data sets where allowed by SMP/E, your installation personnel, or administration staff. For instance, this topic refers to samples in hlq.SEZAINST library as simply in SEZAINST. Your installation might choose a data set name of SYS1.SEZAINST, CS390.SEZAINST or other high level qualifiers for the data set name.

The following terms are used in [Table 1 on page 1](#):

hlq (high-level qualifier)

High-level qualifiers permit you to associate an application's configuration data set with a particular job name or TSO user ID, or permit you to use a default configuration data set for the application. The possible high-level qualifiers are:

userid

The TSO user ID which invoked the application

jobname

The application's batch JCL JOB name or the name of the application's started procedure

default hlq

TCP/IP is distributed with a default hlq of TCPIP. To override the default used by dynamic data set allocation, specify the DATASETPREFIX statement in the TCPIP.DATA configuration file. For most servers or functions, the data set whose high-level qualifier matches the DATASETPREFIX value is the last data set in the search order. The data set whose high-level qualifier matches the DATASETPREFIX value is not the last in the search order for TCPIP.DATA configuration information.

SEZAINST (member)

Indicates that the sample is a member of the SEZAINST data set. This hlq value is the high-level qualifier specified during TCP/IP installation.

For some configuration information, the search order depends on the type of application (z/OS UNIX or native MVS). For a description of these search orders, see [search orders used in the z/OS UNIX environment](#) and [Search orders used in the native MVS environment](#) in [z/OS Communications Server: IP Configuration Guide](#).

TCP/IP configuration data sets

[Table 1 on page 1](#) lists the configuration MVS data sets and z/OS UNIX files used by the TCP/IP servers and functions. The table includes the name of the sample data set or file that is provided by Communications Server, and the way the data set or file is used.

Table 1. TCP/IP configuration data sets

Name (search order)	Copied from	Usage
ADNR.CONF The MVS data set or z/OS UNIX file specified on the CONFIG DD statement in the automated domain name registration started procedure	SEZAINST(ADNRCNF)	Contains automated domain name registration configuration statements.

Table 1. TCP/IP configuration data sets (continued)

Name (search order)	Copied from	Usage
CSSMTP.CONF 1. The MVS data set or z/OS UNIX file referenced by the CONFIG DD statement in the CSSMTP application started procedure 2. <i>jobname.CSSMTP.CONF</i>	SEZAINST(CSSMTPCF)	Contains CSSMTP application configuration statements.
Defense Manager daemon (DMD) configuration 1. The MVS data set or z/OS UNIX file specified by the DMD_FILE environment variable 2. <i>/etc/security/dmd.conf</i>	<i>/usr/lpp/tcpip/samples/dmd.conf</i>	Contains DMD configuration statements.
Digital certificate access server (DCAS) configuration 1. The MVS data set or z/OS UNIX file that the DCAS_CONFIG_FILE environment variable specified 2. <i>/etc/dcas.conf</i> 3. <i>tsouserid.DCAS.CONF</i> 4. <i>TCPIP.DCAS.CONF</i>	No sample provided.	Contains DCAS configuration statements.
<i>/etc/hosts</i>	No sample provided.	One of the possible local host files used for IPv4 name query. For information about creating <i>/etc/hosts</i> directory, see z/OS Communications Server: IP Configuration Guide
<i>hlq.ETC.IPNODES</i>	SEZAINST(EZBREIPN)	One of the local host files used for IPv6 name query, or IPv4 and IPv6 name query when COMMONSEARCH is specified in the resolver setup file.
<i>/etc/mail/ezatmail.cf</i>	<i>/usr/lpp/tcpip/samples/ezatmail.cf</i>	Defines sendmail to CSSMTP bridge configuration statements.

Table 1. TCP/IP configuration data sets (continued)

Name (search order)	Copied from	Usage
ETC.PROTO	usr/lpp/tcpip/samples/protocol	Used to map types of protocol to integer values to determine the availability of the specified protocol. Required by several z/OS Communications Server components. The search order depends on the type of application (z/OS UNIX or native MVS).
ETC.RPC	SEZAINST(ETCRPC)	Defines RPC applications to the Portmapper function.
ETC.SERVICES	usr/lpp/tcpip/samples/services	Establishes port numbers for servers using TCP and UDP. Required for z/OS UNIX SNMP and OMPROUTE (if the RIP protocol is used). The search order depends on the type of application (z/OS UNIX or native MVS).
/etc/syslog.conf	/usr/lpp/tcpip/samples/syslog.conf	Configuration file for the syslog daemon (syslogd).
FTP.DATA 1. -f command line parameter (FTP client only) 2. The MVS data set or z/OS UNIX file specified on the SYSFTPD DD statement in the FTP server started procedure 3. <i>userid/jobname</i> .FTP.DATA 4. /etc/ftp.data 5. SYS1.TCPPARMS(FTPDATA) 6. <i>hlq</i> .FTP.DATA	SEZAINST(FTCDATA) for the client and (FTPDATA) for the server	Overrides default FTP client and server parameters for the FTP server. For more information about the <i>hlq</i> , <i>jobname</i> , or <i>userid</i> values, see Chapter 14, “File Transfer Protocol,” on page 587.
HOSTS.LOCAL	SEZAINST(HOSTS)	Input data set to MAKE SITE for generation of HOSTS.ADDRINFO and HOSTS.SITEINFO.

Table 1. TCP/IP configuration data sets (continued)

Name (search order)	Copied from	Usage
IKE daemon configuration 1. The MVS data set or z/OS UNIX file specified by the IKED_FILE environment variable 2. /etc/security/iked.conf	/usr/lpp/tcpip/samples/iked.conf	Contains IKE configuration statements.
INETD.CONF The MVS data set or z/OS UNIX file specified on the EXEC DD statement in the INETD started procedure	/samples/inetd.conf	Provides configuration management statements of generic servers for the Internet Daemon (InetD). InetD handles rlogin, telnetd, rshd, rexec, and other applications. For more information about InetD, see z/OS UNIX System Services Planning .
LBADV.CONF The MVS data set or z/OS UNIX file specified on the CONFIG DD statement in the z/OS Load Balancing Advisor started procedure	SEZAINST(LBADVCNF)	Contains z/OS Load Balancing Advisor configuration statements.
LBAGENT.CONF The MVS data set or z/OS UNIX file specified on the CONFIG DD statement in the z/OS Load Balancing Agent started procedure.	SEZAINST(LBAGECNF)	Contains z/OS Load Balancing Agent configuration statements.
LPD.CONFIG	SEZAINST(LPDDATA)	Configures the Line Printer Daemon for the Remote Print Server.
MIBS.DATA 1. The name of a z/OS UNIX file or an MVS data set specified by the MIBS_DATA environment variable 2. /etc/mibs.data z/OS UNIX file	No sample provided	Defines textual names for MIB objects for the z/OS UNIX snmp command.
Network security services (NSS) server configuration 1. The name of a z/OS UNIX file or MVS data set specified by the NSSD_FILE environment variable. 2. /etc/security/nssd.conf	/usr/lpp/tcpip/samples/nssd.conf	Contains NSS server configuration statements.

Table 1. TCP/IP configuration data sets (continued)

Name (search order)	Copied from	Usage
OMPROUTE configuration 1. The MVS data set or z/OS UNIX file specified on the OMPCFG DD statement in the OMPROUTE started procedure. 2. The MVS data set or z/OS UNIX file specified by the OMPROUTE_FILE environment variable 3. /etc/omproute.conf 4. <i>hlq</i> .ETC.OMPROUTE.CONF	SEZAINST(EZAORCFG)	Contains OMPROUTE configuration statements.
OSNMP.CONF 1. /etc/osnmp.conf 2. /etc/snmpv2.conf	/usr/lpp/tcpip/samples/snmpv2.conf	Defines target host security parameters for the osnmp command.
OSNMPD.DATA 1. The MVS data set or z/OS UNIX file specified by the OSNMPD_DATA environment variable 2. /etc/osnmpd.data file system file 3. The MVS data set z/OS UNIX file specified on the OSNMPD DD statement in the agent started procedure 4. <i>jobname</i> .OSNMPD.DATA, where <i>jobname</i> is the name of the job used to start the SNMP agent 5. SYS1.TCPPARMS(OSNMPD) 6. <i>hlq</i> .OSNMPD.DATA, where <i>hlq</i> either defaults to TCPIP or is specified on the DATASETPREFIX statement in the TCPIP.DATA file being used	/usr/lpp/tcpip/samples/osnmpd.data	Used by SNMP for setting values for selected MIB objects.
PAGENT.CONF 1. File or data set specified with -c startup option 2. File or data set specified with PAGENT_CONFIG_FILE environment variable 3. /etc/pagent.conf	/usr/lpp/tcpip/samples/pagent.conf	Defines Policy Agent configuration parameters and optionally defines QoS service policies (rules and actions).

Table 1. TCP/IP configuration data sets (continued)

Name (search order)	Copied from	Usage
PROFILE.TCPIP 1. The MVS data set specified on the PROFILE DD statement in the TCP/IP stack started procedure. 2. <i>jobname.nodename.TCPIP</i> 3. <i>TCPIP.nodename.TCPIP</i> 4. <i>jobname.PROFILE.TCPIP</i> 5. <i>TCPIP.PROFILE.TCPIP</i>	SEZAINST(SAMPPROF)	Provides TCP/IP initialization parameters and specifications for network interfaces and routing.
PW.SRC 1. The MVS data set or z/OS UNIX file specified by the PW_SRC environment variable 2. /etc/pw.src file system file 3. The MVS data set or z/OS UNIX file specified on SYSPWSRC DD statement in the started agent procedure 4. <i>jobname.PW.SRC</i> , where <i>jobname</i> is the name of the job used to start the SNMP agent 5. SYS1.TCPPARMS(PWSRC) 6. <i>hlq.PW.SRC</i> , where <i>hlq</i> either defaults to TCPIP or is specified on the DATASETPREFIX statement in the TCPIP.DATA file being used	No sample provided	Defines a list of community names used when accessing objects on a destination SNMP agent.
Resolver Setup File	SEZAINST (RESSETUP)	Provides configuration statements for the resolver.
RSVPD.CONF 1. File or data set specified with -c startup option 2. File or data set specified with RSVPD_CONFIG_FILE environment variable 3. /etc/rsvpd.conf 4. <i>hlq.RSVPD.CONF</i>	/usr/lpp/tcpip/samples/rsvpd.conf	Defines RSVP Agent configuration parameters.
SMTPNOTE clist System CLIST data set	SEZAINST(SMTPNOTE)	Defines the <i>note</i> parameters for the CSSMTP application.

Table 1. TCP/IP configuration data sets (continued)

Name (search order)	Copied from	Usage
SNMPD.Boots 1. The name of a z/OS UNIX file system file or an MVS data set specified by the SNMPD_Boots environment variable. 2. /etc/snmpd.Boots	No sample provided	Defines the SNMP agent security and notification destinations. Note: If the SNMPD.Boots file is not provided, the SNMP agent creates the file. If multiple SNMPv3 agents are running on the same MVS image, use the environment variable to specify different SNMPD.Boots files for the different agents. For security reasons, ensure unique engine IDs are used for different SNMP agents.
SNMPD.CONF 1. The name of a z/OS UNIX file system file or an MVS data set specified by the SNMPD_CONF environment variable. 2. /etc/snmpd.conf Note: The first file found in the search order is used.	/usr/lpp/tcpip/samples/snmpd.conf	Defines the SNMP agent security and notification destinations. Note: If the SNMPD.CONF file is found, the PW.SRC file and the SNMPTRAP.DEST files are not used.

Table 1. TCP/IP configuration data sets (continued)

Name (search order)	Copied from	Usage
SNMPTRAP.DEST 1. The MVS data set or z/OS UNIX file specified by the SNMPTRAP_DEST environment variable 2. /etc/snmptrap.dest file system file 3. The MVS data set or z/OS UNIX file specified on SNMPTRAP DD statement in the agent started procedure 4. <i>jobname</i> .SNMPTRAP.DEST, where <i>jobname</i> is the name of the job used to start the SNMP agent 5. SYS1.TCPPARMS(SNMPTRAP) 6. <i>hlq</i> .SNMPTRAP.DEST, where <i>hlq</i> either defaults to TCPIP or is specified on the DATASETPREFIX statement in the TCPIP.DATA file being used	No sample provided	Defines a list of managers to which the SNMP agent sends traps.
TCPIP.DATA	SEZAINST(TCPDATA)	Provides parameters for TCP/IP client programs. The search order depends on the type of application (z/OS UNIX or native MVS). See ./resolversetupandtcipdataconfig.dita#syp for more information.
TNDBCSCN The MVS data set specified on the TNDBCSCN DD statement in the TN3270E Telnet server started procedure	SEZAINST(TNDBCSCN)	Provides configuration parameters for Telnet 3270 Transform support.
TRAPFWD.CONF 1. A z/OS UNIX system file or an MVS data set specified by the TRAPFWD_CONF environment variable 2. /etc/trapfwd.conf	No sample provided	Defines addresses to which the Trap Forwarder Daemon forwards traps. Note: If the environment variable is set and if the file specified by the environment variable is not found, the Trap Forwarder daemon terminates.

Table 1. TCP/IP configuration data sets (continued)

Name (search order)	Copied from	Usage
VTAMLST The VTAM definitions added to the ATCCONxx member of the MVS data set specified on the VTAMLST DD statement in the VTAM started procedure	SEZAINST(VTAMLST)	Defines VTAM applications and associated characteristics. Entries are required for the TN3270E Telnet server.

Chapter 2. TCP/IP profile (PROFILE.TCPIP) and configuration statements

This topic contains the following information:

- [“Summary of TCP/IP address space configuration statements” on page 11](#)
- [“PROFILE.TCPIP search order” on page 14](#)
- [“Statement syntax for configuration statements” on page 14](#)
- Statements and descriptions

Configuring the stack for IPv6 is done in the BPXPRMxx member of SYS1.PARMLIB. For more information about configuring the stack to support IPv6, see [z/OS Communications Server: IP Configuration Guide](#) or [z/OS Communications Server: IPv6 Network and Appl Design Guide](#).

Summary of TCP/IP address space configuration statements

Table 2 on page 11 contains a brief description of each configuration statement, along with the location of more information.

Table 2. Summary of TCP/IP address space configuration statements

Statement	Description	See
AUTOLOG	Indicates which procedures should be automatically started when TCP/IP is started.	“AUTOLOG statement” on page 16
BEGINROUTES, ENDROUTES	Defines main routing table entries in standard Berkeley Software Distribution (BSD) format for static routes.	“BEGINROUTES statement” on page 19
BSDROUTINGPARMS	Defines network interface information. The statement is used to provide interface-level characteristics to interfaces used for static routing.	“BSDROUTINGPARMS statement” on page 27
DEFADDRTABLE	Defines the policy table for IPv6 default address selection.	“DEFADDRTABLE statement” on page 30
DELETE	Removes a DEVICE, LINK, PORT, or PORTRANGE.	“DELETE statement” on page 32
DEVICE and LINK statements	Defines an IPv4 device. To configure your devices, add the appropriate DEVICE and LINK statements to the configuration data set. The LINK statements show how to define a network interface link associated with the device and are included with the DEVICE statement for that device type.	“Summary of DEVICE and LINK statements” on page 35
DEVICE and LINK	CTC devices	“DEVICE and LINK - CTC devices statement” on page 39

Table 2. Summary of TCP/IP address space configuration statements (continued)

Statement	Description	See
DEVICE and LINK	MPCIPA HiperSockets devices	“DEVICE and LINK - MPCIPA HiperSockets devices statement” on page 41
DEVICE and LINK	MPCPTP devices Used for: <ul style="list-style-type: none"> • EE • HPDT • Communication between stacks • XCF connections 	“DEVICE and LINK - MPCPTP devices statement” on page 44
DEVICE and LINK	Virtual devices	“DEVICE and LINK - VIRTUAL devices statement” on page 47
GLOBALCONFIG	Passes global configuration parameters to TCP/IP.	“GLOBALCONFIG statement” on page 49
HOME	Provides a list of home addresses and associated link names.	“HOME statement” on page 76
INCLUDE	Causes another data set that contains profile configuration statements to be included at this point.	“INCLUDE statement” on page 80
INTERFACE statements	Defines an IPv4 interface for Network Express, OSA QDIO Ethernet, HiperSockets, or static VIPA, or defines an IPv6 interface.	“Summary of INTERFACE statements” on page 80
INTERFACE	EQENET interfaces. Specifies IPv4 Network Express EQDIO interfaces.	“Summary of INTERFACE statements” on page 80
INTERFACE	EQENET6 interfaces. Specifies IPv6 Network Express EQDIO interfaces.	“Summary of INTERFACE statements” on page 80
INTERFACE	IPAQENET interfaces Specifies IPv4 OSA QDIO interfaces.	“INTERFACE - IPAQENET OSA-Express QDIO interfaces statement” on page 84
INTERFACE	IPAQENET6 interfaces Specifies IPv6 OSA QDIO interfaces.	“INTERFACE - IPAQENET6 OSA-Express QDIO interfaces statement” on page 116
INTERFACE	IPAQIDIO interfaces Configures IPv4 HiperSockets connectivity.	“INTERFACE - IPAQIDIO HiperSockets interfaces statement” on page 105
INTERFACE	IPAQIDIO6 interfaces Configures IPv6 HiperSockets connectivity.	“INTERFACE - IPAQIDIO6 HiperSockets interfaces statement” on page 131

Table 2. Summary of TCP/IP address space configuration statements (continued)

Statement	Description	See
INTERFACE	<p>LOOPBACK6 interface</p> <p>Allows you to add additional IP addresses for LOOPBACK6 in the initial profile or in a data set used with the VARY TCPIP,,OBEYFILE command.</p>	“INTERFACE - LOOPBACK6 interface statement” on page 136
INTERFACE	<p>MPC Point-to-Point interfaces</p> <p>Updated Data Link Control supports IPv6 traffic.</p>	“INTERFACE - MPCPTP6 interfaces statement” on page 137
INTERFACE	<p>VIRTUAL interfaces</p> <p>Specifies IPv4 static virtual interfaces.</p>	“INTERFACE - VIRTUAL interfaces statement” on page 109
INTERFACE	<p>VIRTUAL6 interfaces</p> <p>Specifies IPv6 static virtual interfaces.</p>	“INTERFACE - VIRTUAL6 interfaces statement” on page 141
IPCONFIG	Specifies IP configuration values.	“IPCONFIG statement” on page 143
IPCONFIG6	Specifies IPv6 configuration values.	“IPCONFIG6 statement” on page 156
IPSEC	Specifies policy for the IP Security function.	“IPSEC statement” on page 166
ITRACE	Controls tracing for configuration, the SNMP subagent, commands, and the autolog subtask.	“ITRACE statement” on page 179
NETACCESS, ENDNETACCESS	Configures network access.	“NETACCESS statement” on page 181
NETMONITOR	Activates or deactivates network management programming interfaces.	“NETMONITOR statement” on page 185
OSAENTA	Defines the conditions used to select Ethernet frames from an OSA as candidates for tracing and subsequent analysis.	“OSAENTA statement” on page 193
PKTTRACE	Defines the conditions used to select IP packets as candidates for tracing and subsequent analysis.	“PKTTRACE statement” on page 200
PORT	Reserves a port for one or more given job names or controls application access to unreserved ports.	“PORT statement” on page 207
PORTRANGE	Reserves a range of ports for one or more job names.	“PORTRANGE statement” on page 216
PRIMARYINTERFACE	Specifies which link is to be considered the primary interface.	“PRIMARYINTERFACE statement” on page 220

Table 2. Summary of TCP/IP address space configuration statements (continued)

Statement	Description	See
SACONFIG	Specifies parameters for the TCP/IP SNMP subagent.	“SACONFIG statement” on page 221
SMFCONFIG	Provides SMF logging for Telnet, FTP, IPsec, TCP API, and TCP stack activity.	“SMFCONFIG statement” on page 224
SMFPARMS	Provides SMF logging for Telnet and FTP client activity and TCP API activity.	“SMFPARMS statement” on page 232
SOMAXCONN	Specifies a maximum connection length for the connection request queues created by the socket call listen().	“SOMAXCONN statement” on page 233
SRCIP	Designates source IP addresses to be used for outbound TCP connections that are initiated by specified jobs or destined for specified IP addresses, networks, or subnets.	“SRCIP statement” on page 233
START	Starts the specified device or interface.	“START statement” on page 242
STOP	Stops the specified device or interface.	“STOP statement” on page 243
TCPCONFIG	Specifies TCP parameters.	“TCPCONFIG statement” on page 244
UDPCONFIG	Specifies UDP parameters.	“UDPCONFIG statement” on page 251
VIPADYNAMIC, ENDVIPADYNAMIC	Specifies a block of definitions related to dynamic VIPAs. This includes VIPABACKUP, VIPADEFINE, VIPADELETE, VIPADISTRIBUTE, and VIPARANGE.	“VIPADYNAMIC statement summary” on page 253

PROFILE.TCPIP search order

The search order for accessing PROFILE.TCPIP information is as follows. The first file found in the search order is used.

1. //PROFILE DD statement
2. *jobname.nodename.TCPIP*
3. *TCPIP.nodename.TCPIP*
4. *jobname.PROFILE.TCPIP*
5. *TCPIP.PROFILE.TCPIP*

Statement syntax for configuration statements

Statement syntax is the same in both the configuration data set *hlq.PROFILE.TCPIP* and the VARY TCPIP,,OBEYFILE command data set.

- Entries in a configuration data set are free format; blanks, comments, and end-of-record are ignored.

- A configuration statement consists of a statement name followed by a required blank, and usually one or more positional arguments. Separate each argument by one or more blanks or end-of-record.
- A semicolon begins a comment. Comments act as blanks, separating words without affecting their meaning.
- An argument followed by a comment must have a blank before the semicolon.
- Statements can be split across multiple lines.
- Sequence numbers are not allowed.
- Lowercase letters are translated to uppercase before the statements are executed, except for those parameters that support mixed case entries. For example, the SNMP community name is case sensitive.
- An END statement terminates a number of statements, such as AUTOLOG. If the END statement is omitted, all subsequent tokens in the data set are interpreted as parameters for that configuration statement.
- If a syntax error is encountered in a list of parameters, such as a HOME list, the rest of the entries in the list are ignored.

Tip: Because some statements skip the entry in error and continue to process the remaining entries, this does not apply to all statements.

- Profile statements do have some order restrictions. The basic order is any statement that references a name defined in another statement must follow that statement. For example, LINK statements must follow the DEVICE statement that defines the device referenced by the link. Statements referencing links, for example, BEGINROUTES, HOME, and TRANSLATE, must follow the referenced LINK statement.
- Static system symbols can be used in profile statements.
- For those profile statements where you can modify parameters by respecifying the statement, the only parameter values that are changed when the statement is respecified are those parameters explicitly coded on the respecified statement. The parameter values that are not explicitly coded on the statement are not changed to the default value of the parameter; they retain their last specified value. For example, if you specify: IPCONFIG NODATAGRAMFWD in an initial profile data set, and then specify: IPCONFIG IGNOREREDIRECT in a data set referenced by a VARY TCPIP,,OBEYFILE command, the NODATAGRAMFWD parameter remains in effect and is not changed to the default parameter value of DATAGRAMFWD NOFWMULTIPATH.
- **Rules:** User-defined names on configuration statements must adhere to the following rules:
 - Each character must be a non-blank printable character. The set of non-blank printable characters includes alphabetic and numeric characters, and the following special characters:

. < (+ | & ! \$) ^ - / % _ > ? ` : # @ ' " ~ [{ } \

Restriction:

- The name must not be one of the following values:
 - A hexadecimal number
 - An integer
 - An IP address
- If the name is an MVS job name, started procedure name, or part of a RACF® resource name, the characters that are used for the name must adhere to the rules for these types of MVS names.
- The following characters are not allowed:
 - Comma (,)
 - Semicolon (;)
 - Equal (=)
 - Asterisk (*)
- IPv4 IP addresses can be partially defined in a Profile statement where an IP address is expected. If a user enters 100, it is interpreted as 100.0.0.0, and 1.2 is interpreted as 1.2.0.0.

- All characters in the configuration data set must be entered in code page IBM-1047.

Guideline: Use the VARY TCPIP,,SYNTAXCHECK command to verify that the configuration statements in the configuration data set are free of syntax errors before starting the TCP/IP stack or activating a new profile using the Vary TCPIP,,OBEYFILE command to activate the profile. To use the syntax checker before starting the stack, you must issue the VARY TCPIP,,SYNTAXCHECK command on a system that has already started TCP/IP. See [VARY TCPIP,,SYNTAXCHECK](#) in *z/OS Communications Server: IP System Administrator's Commands* for more information.

AUTOLOG statement

Use the AUTOLOG statement to provide a list of MVS started procedures to be started by the Autolog task when TCP/IP is started.

In addition to initially starting these procedures, the AUTOLOG statement can provide a monitoring function that ensures that these started procedures are still active. To request this monitoring function for a started procedure, reserve one or more ports for the procedure using the PORT or PORTRANGE profile statement. Do not specify the NOAUTOLOG parameter. The *proc_name* or JOBNAME value on the AUTOLOG statement entry must match the *jobname* value on the port reservation statement. Every 5 minutes, the autolog monitoring function ensures that there is either a TCP listening socket, or a UDP socket, active for those port reservations where:

- NOAUTOLOG was not specified
- The *jobname* matches the AUTOLOG statement *proc_name* or JOBNAME value

If no active socket is found for any of the reserved ports for the started procedure, then the Autolog monitoring function performs the following actions:

- Determines if the started procedure address space is still active. If it is still active, the autolog function cancels the started procedure.

Note: If the started procedure has multiple reserved ports (for example, INETD1) and if any one of those ports does not have an active socket, the autolog function will cancel the started procedure. This can cause disruption to the active sockets for the other reserved ports for that started procedure address space.

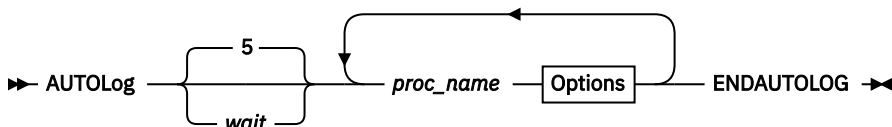

- Restarts the started procedure.

Guideline: Ensure that ports that are used by the started procedure (for example, in /etc/services or specified on an optional port parameter for the started procedure) match the reserved ports in the port reservation statement. A mismatched port can cause the autolog monitoring function to cancel the started procedure.

Restriction: Do not use AUTOLOG to automatically start generic servers (those without affinity to a specific stack, such as TN3270E and FTP) when multiple stacks (CINET) are running. Do not use AUTOLOG to automatically start servers defined as non-cancelable (such as TN3270E) in the program properties table (PPT). Instead, use a method other than AUTOLOG to automatically start generic servers. For more information about [generic servers](#), see *z/OS Communications Server: IP Configuration Guide*.

Syntax

Rule: Specify the parameters in the order shown. The optional parameters following the *proc_name* parameter can be specified in any order.

Options

Parameters

wait

The time TCP/IP should allow for a procedure to come down when, at startup, it is still active and TCP/IP is attempting to AUTOLOG the procedure again. This could happen if the procedure did not come down when TCP/IP was last shut down.

The default is 5 minutes. *wait* can be set to any value from 0 to 30 minutes. If a *wait* value outside the valid range is specified, the default of 5 minutes is used. When a *wait* value of 0 is specified, TCP/IP startup does not cancel and restart any procedures in the autolog list that are already started.

TCP/IP does not cancel the procedure at initialization. TCP/IP checks every 10 seconds (until the time interval specified by *wait* has expired) to check if the procedure has come down. If the procedure comes down during one of these 10 second intervals, it is restarted. If the procedure is still active when the time interval specified by *wait* expires, then TCP/IP cancels and restarts the procedure.

This value is only used at startup of TCP/IP and is never referenced again.

proc_name

A procedure that the TCP/IP address space should start.

Requirement: The procedure name must be a member of a cataloged procedure library.

PARMSTRING "parm_string"

A string to be added following the START *procedure_name*. Do not include the comma. The "parm_string" is 115 characters or less, not counting the double quotation marks around the string.

Restriction: The entire "parm_string" must be on one line and must not contain a double quotation mark.

JOBNAME job_name

The job name used for the PORT reservation statement. This can be identical to the *proc_name*, but for z/OS UNIX jobs that spawn listener threads it is not. If the *job_name* is not explicitly set, it is assumed to be the same as the *proc_name*.

DELAYSTART

An optional keyword that indicates that the procedure does not start until the TCP/IP stack has completed one or more processing steps. One or more optional subparameters determine which processing steps must be completed before the procedure is started. If no additional subparameters are configured, then the procedure is started after the TCP/IP stack has joined the sysplex group and has processed its dynamic VIPA configuration.

If this keyword is not specified, the procedure is started after the TCP/IP stack is started, whether or not the stack has completed any of the processing steps.

DVIPA

When this subparameter is specified, the procedure starts after the TCP/IP stack has joined the sysplex group and has processed its dynamic VIPA configuration. This is the default setting that occurs if DELAYSTART is coded without any subparameters.

Guideline: Use this subparameter to delay the start of a procedure that binds to a dynamic VIPA address that is created during TCP/IP stack initialization or when the procedure performs the bind. Dynamic VIPAs cannot be created until after the stack has joined the sysplex group and

has processed its dynamic VIPA configuration; this keyword prevents the procedure from starting before the dynamic VIPA can be created. For information about when the TCP/IP stack joins the sysplex group, see [sysplex problem detection and recovery in z/OS Communications Server: IP Configuration Guide](#).

Tip: The stack issues console message EZD1214I INITIAL DYNAMIC VIPA PROCESSING HAS COMPLETED FOR *jobname* when dynamic VIPA configuration processing is complete. After this console message is displayed, the autolog procedures waiting on this processing start.

TTLS

When this subparameter is specified, the procedure starts after the Policy Agent has successfully installed the AT-TLS policy in the TCP/IP stack and AT-TLS services are available.

Guideline: Use this subparameter to delay the start of the procedures that depend on AT-TLS services.

Tip: The message EZZ4250I AT-TLS SERVICES ARE AVAILABLE FOR *jobname* is issued after the Policy Agent has installed the policy and the AT-TLS services are available. After this console message is issued, the autolog procedures waiting on this processing start.

Rules:

- Do not specify the DELAYSTART DVIPA (or DELAYSTART with no subparameters) for your OMPROUTE procedure if you configure the DELAYJOIN parameter on the GLOBALCONFIG SYSPLEXMONITOR profile statement.
- Do not specify the DELAYSTART DVIPA (or DELAYSTART with no subparameters) for your Policy Agent, IKED, or NSSD procedures if you configure the DELAYJOINIPSEC parameter on the GLOBALCONFIG SYSPLEXMONITOR profile statement.

Note: Policy Agent, IKED, or NSSD are generic servers and AUTOLOG would not typically be used to start them.

- If TCPCONFIG TTLS is not specified in the initial profile, the DELAYSTART TTLS subparameter is ignored because AT-TLS services are not being used.

Results:

- When more than one DELAYSTART subparameter is specified, all of the processing steps defined for those subparameters must complete before the procedure is started.
- When at least one DELAYSTART subparameter is specified, but DVIPA is not specified, the default behavior does not occur; the procedure does not wait for dynamic VIPA configuration processing to complete before starting.

ENDAUTOLOG

The ENDAUTOLOG statement specifies the end of the AUTOLOG parameters to pass to TCP/IP.

Steps for modifying

To modify the AUTOLOG statement, use the VARY TCPIP,,OBEYFILE command with a data set that contains a new AUTOLOG statement. The first AUTOLOG statement in the data set replaces all previous AUTOLOG statements. Subsequent AUTOLOG statements in the same data set append to the previous statements in the data set.

For more information about [VARY TCPIP Command](#), see [z/OS Communications Server: IP System Administrator's Commands](#).

Examples

This example shows how to include several servers in the AUTOLOG statement:

```
AUTOLOG
  FTPD JOBNAME FTPD1      ; FTP Server
  LPSEVE      ; LPD Server
  PORTMAP JOBNAME PORTMAP1 ; USS Portmap server (SUN 4.0)
```

```

RXSERVE          ; Remote Execution Server
OSNMPD           ; SNMP Agent Server
SNMPQE           ; SNMP Client Address space
MVS NFS          ; Network File System Server
ENDAUTOLOG

```

The next example shows how to autolog two procedures using the PARMSTRING, DELAYSTART, and JOBNAME options.

- The first procedure is named MYPROC1. This procedure does not start until after the TCP/IP stack has joined the sysplex group and has processed its dynamic VIPA configuration. When the procedure is started, it should use the following MVS console start command:

```
S MYPROC1,PARMS='-w 100',ID=XYZ
```

- The second procedure has a listening z/OS UNIX thread that is the first spawned task. You can use the MVS DISPLAY ACTIVE,LIST console command to determine the job name. If the MYPROC2 procedure ends abnormally or stops listening, the following MVS console start command is entered:

```
S MYPROC2,PARMS='-dzy 50',DSN='HLQ.'
```

- The third procedure is named MYPROC3. This procedure does not start until AT-TLS services are available.

```

AUTOLOG 20
MYPROC1 PARMSTRING "PARMS='-w 100',ID=XYZ" DELAYSTART
MYPROC2 PARMSTRING "PARMS='-dzy 50',DSN='HLQ.'" JOBNAME MYPROC21
MYPROC3 DELAYSTART TTLS
ENDAUTOLOG

PORT 2010 TCP MYPROC1
      2011 TCP MYPROC21
      2012 TCP MYPROC3

```

Usage notes

The AUTOLOG statement can be used to start both socket and non-socket applications. For any procedure that has no port reserved in the PORT statement, AUTOLOG initially starts the procedure when TCP/IP starts. For procedures whose ports are reserved in the PORT statement (and do not have the NOAUTOLOG option specified), each port is checked to make sure that the procedure has an active connection to that port. If a procedure has multiple ports reserved and any one port is inactive, the procedure is canceled and restarted. For TCP connections, the procedure must have a socket open to that port in the LISTEN state. For UDP connections, the procedure must have a socket open to that port.

- [“PORT statement” on page 207](#)
- [“PORTRANGE statement” on page 216](#)

BEGINROUTES statement

Use the BEGINROUTES statement to add static routes to the main route table. You can specify a BSD style syntax or destination IP address and address mask; you can also define the route to be replaceable and define IPv6 static routes.

To configure policy-based route tables, use the RouteTablestatement. For more information, see the policy-based routing information in the [z/OS Communications Server: IP Configuration Guide](#).

IBM Health Checker for z/OS can be used to check whether the total number of indirect routes in a TCP/IP stack routing table exceeds a maximum threshold. When this threshold is exceeded, OMROUTE and the TCP/IP stack may potentially experience high CPU consumption from routing changes. A large routing

table is considered to be inefficient in network design and operation. For more details about IBM Health Checker for z/OS, see [IBM Health Checker for z/OS User's Guide](#).

The destination IP address can be an IPv4 or IPv6 address and does not need to be a fully qualified address.

Requirements:

- The first hop gateway IP address can also support IPv4 or IPv6 addresses, but must be a fully qualified address.
- To add a route over an MPCPTP link to another IP address on the remote host, for example, add an indirect route to a VIPA. This indirect route must contain the following information:
 - A destination that is equal to the other IP address
 - A first_hop value that is equal to the remote IP address of the MPCPTP link
 - A link_name value that is equal to the name of the MPCPTP link

The IP static routes can be modified by the following methods:

- Replace the routing table using the VARY TCPIP,,OBEYFILE command.
- Incoming ICMP Redirect packets can replace IPv4 static routes, and also add routes to the routing table.
- Incoming ICMPv6 Redirect packets can replace IPv6 static routes, and also add routes to the routing table.
- Dynamic routing daemons (for example, OMPROUTE) can replace IPv4 or IPv6 replaceable static routes, as well as add dynamic routes to the routing table.
- Router advertisements can update IPv6 replaceable static routes, as well as add dynamic routes to the routing table.

The first BEGINROUTES statement of each configuration data set that is issued replaces all static routes in the existing routing table with the new route information. All static routes are deleted, along with all routes learned by way of ICMP or ICMPv6 redirects. Routes created by OMPROUTE and router advertisements are not deleted. Subsequent BEGINROUTES statements in the same data set add entries to the routing table.

Restrictions:

- Static routes defined by the BEGINROUTES-ENDROUTES block cannot be replaced by OMPROUTE or router advertisements unless the static routes are defined as replaceable. If you want OMPROUTE or router advertisements to begin managing all routes, an empty BEGINROUTES-ENDROUTES block can be used in a VARY TCPIP,,OBEYFILE command data set to eliminate the existing static routes.
- ROUTE entries within a BEGINROUTES-ENDROUTES block can be coded only for LINK names or INTERFACE names that exist when the entry is processed.

Result: When an incorrect ROUTE entry statement is encountered, the ROUTE entry is rejected with an error message, but the rest of the ROUTE entries in that BEGINROUTES-ENDROUTES block are still processed. Subsequent BEGINROUTES-ENDROUTES blocks in the same initial profile or VARY TCPIP,,OBEYFILE command data set, are also processed.

Route precedence is as follows:

- If a route exists to the destination address (a host route), it is chosen first.
- For IPv4, if subnet, network, or supernet routes exist to the destination, the route with the most specific network mask (the mask with the most bits on) is chosen second.
- For IPv6, if prefix routes exist to the destination, the route with the most specific prefix is chosen second.
- If the destination is a multicast destination and multicast default routes exist (valid only for IPv4), the route with the most specific multicast address is chosen third.
- Default routes are chosen when no other route exists to a destination.

Rule: The required parameters for this statement must be specified in the order shown here. The optional parameters can be specified in any order.

Syntax

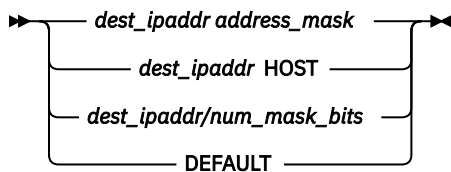

Route Entry

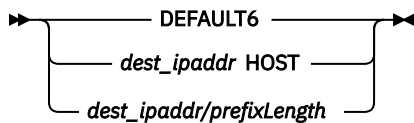

Destination

IPv4_Destination

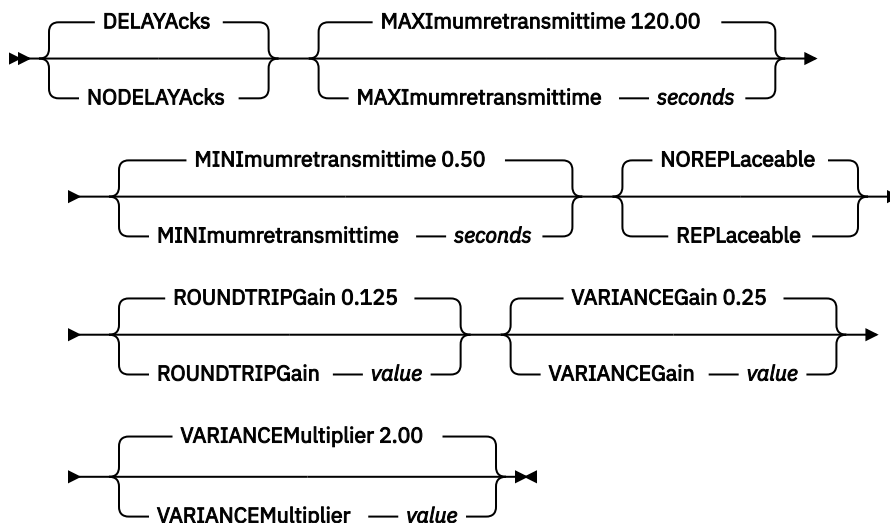

IPv6_Destination

Packet size

Options

Parameters

dest_ipaddr

The destination IPv4 or IPv6 address.

The DEFAULT/DEFAULT6 keyword in this field specifies default routes. For IPv4, the destination address can be a host, network, subnet, supernet or default address. For IPv6, the destination address can be a host, prefix or default address. In addition, multiple routes having an identical destination IP address and address mask can be specified. When multiple routes are specified, all of them are used when multipath is enabled on the IPCONFIG/IPCONFIG6 statement; otherwise, only the first active route specified is used.

Requirement: An IPv4 address must be fully qualified.

address_mask

The BSD style address mask for an IPv4 route. If the HOST keyword is specified in this field, it is a host route with a mask of 255.255.255.255.

num_mask_bits

An integer value in the range 1 - 32 that represents the number of leftmost significant bits for the address mask of an IPv4 route.

prefixLength

An integer value in the range 1 - 128 representing the number of bits in the *dest_ipaddr* value that are used to determine the destination address of the IPv6 route.

gateway_addr

The host IPv4 or IPv6 address of a gateway or router that you can reach directly, and that forwards packets for the destination network or host over the interface that is identified by *interface_name*.

Requirement: This value must be either a fully qualified address or an equal sign (=), meaning that the messages are routed directly to destinations on that network or directly to that host. The equal sign is not supported for DEFAULT or DEFAULT6 route entries. It cannot be a local IP address on this TCP/IP stack. A local IP address can be defined on the HOME, INTERFACE, VIPADEFINE, or IPCONFIG/IPCONFIG6 DYNAMICXCF statement.

interface_name

The name of the interface through which packets are sent to the specified destination.

Requirement: The interface name must be previously defined in a LINK or INTERFACE statement. VIPA interfaces are not allowed on the ROUTE entry statement.

MTU *mtu_size*

The maximum transmission unit (MTU) in bytes for the destination. This value can be up to 65535. The keyword DEFAULTSIZE in this field requests that TCP/IP supply a default value of 576 for IPv4 routes and 1280 for IPv6 routes.

See [Figure 1 on page 36](#) for more information about the largest MTU value supported by each IPv4 link type.

See [Table 6 on page 81](#) for more information about the largest MTU value supported by each IPv6 interface type.

See the Usage notes in this topic for packet size considerations.

Tip: See z/OS Communications Server: IP Configuration Guide, under section, Maximum transmission unit considerations, for additional information about how TCP/IP uses the MTU to determine the largest size frame to send.

REPLACEABLE | NOREPLACEABLE

Indicates whether or not the static route can be replaced by OMPROUTE and router advertisements when a dynamic route to the same destination is discovered.

NOREPLACEABLE

Indicates that static routes cannot be replaced by dynamic routes. The static route is always used to reach the destination, regardless of when dynamic routes are available. This is the default setting. This parameter can be abbreviated as NOREPL.

REPLACEABLE

Indicates that the static route can be replaced by OMPROUTE and router advertisements when a dynamic route to the same destination is discovered. This parameter can be abbreviated REPL.

Restrictions:

- Only one type (replaceable or nonreplaceable) of static route can be defined to the same destination. All static routes defined to a destination must match the type of the first static route defined to that destination. Any definitions that do not match that type are rejected.
- Replaceable static routes cannot be defined to destination addresses that correspond to dynamic VIPAs for which the TCP/IP stack is a sysplex distributor target.

Tip: You can use the Netstat ROUTE/-1 RSTAT command to display all replaceable static routes currently configured.

Retransmission parameter considerations

The parameters listed in this topic affect the TCP retransmit algorithms. When TCP packets are not acknowledged, TCP begins to retransmit these packets at certain time intervals. If these packets are not acknowledged after a specified number of retransmits, TCP aborts the connection. The time interval between retransmissions increases by approximately twice the previous interval until the packets are acknowledged or the connection times out.

The time intervals between retransmissions and the number of times that packets are retransmitted before the connection times out differs for initial connection establishment and for data packets. For initial connection establishment, the initial time interval is set at approximately 3 seconds and the SYN packet is retransmitted 5 times before the connection is timed out. Data packets use a smoothed Round Trip Time (RTT) as the initial time interval, and data packets are retransmitted 15 times before the connection is timed out. All of the remaining parameters listed in this topic affect the data packet retransmission algorithm. Only the MINIMUMRETRANSMITTIME parameter affects the initial connection establishment.

Tip: A new route lookup is performed after every two retransmissions for a data packet. For more information about the route lookup process, see [Route selection algorithm in z/OS Communications Server: IP Configuration Guide](#). Be careful when you design networks with firewalls. A firewall in an alternate routing path can generate a RESET packet for the rerouted data packets, which causes TCP to abort the connection.

The retransmission parameters enable system administrators who are familiar with TCP/IP transmission performance to alter the flow of TCP/IP data packets and acknowledgments. Under normal circumstances, the following occurs:

- TCP typically waits to receive two packets before sending one ACK to acknowledge the data within them.
- When TCP sends a packet, it waits for an acknowledgment. If it times out before getting an acknowledgment, it resends the packet.

Use the following parameters to adjust the retransmission time-out calculations; slower transmission times prevent packets from being resent as quickly:

- MAXIMUMRETRANSMITTIME
- MINIMUMRETRANSMITTIME
- ROUNDTRIPGAIN
- VARIANCEGAIN
- VARIANCEMULTIPLIER

- DELAYACKS
- NODELAYACKS

TCP uses these values in an algorithm called the TCP Retransmission Timeout Calculation, which is described in RFC 793. When you use this calculation, the following occurs:

- A smoothed round trip time (SRTT) and variance (VAR) is updated from the individual RTT derived from each packet acknowledgement.
- The retransmit time for a new packet is set to twice (approximately) the current SRTT value plus the VAR value.
- Each time a packet is retransmitted, the retransmit time value is doubled.
- The actual interval time used for the initial packet and each retransmission is the retransmit time calculated previously, but limited by the configured MINIMUMRETRANSMITTIME and MAXIMUMRETRANSMITTIME values.

DELAYACKS | NODELAYACKS

Controls transmission of acknowledgments when a packet is received with the PUSH bit on in the TCP header.

NODELAYACKS

Specifies that an acknowledgment is returned immediately when a packet is received with the PUSH bit on in the TCP header. The NODELAYACKS parameter on the BEGINROUTES and RouteTable statements affects only the connections that use this route. Specifying NODELAYACKS on the TCP/IP stack BEGINROUTES profile statement, or on the Policy Agent RouteTable statement, overrides the specification of the DELAYACKS parameter on the TCP/IP stack PORT, PORTRANGE, and TCPCONFIG profile statements.

DELAYACKS

Delays transmission of acknowledgments when a packet is received with the PUSH bit on in the TCP header. The DELAYACKS parameter on the BEGINROUTES and RouteTable statements affects only the connections that use this route. This is the default, but you can override the default by specifying the NODELAYACKS parameter on the TCP/IP stack PORT, PORTRANGE, or TCPCONFIG profile statements.

MAXIMUMRETRANSMITTIME

Limits the TCP retransmission interval. Decreasing this value might decrease the total time it takes a connection to timeout. Specifying MAXIMUMRETRANSMITTIME assures that the interval time never exceeds the specified limit. The minimum value that can be specified for MAXIMUMRETRANSMITTIME is 0. The maximum is 999.990. The default is 120 seconds. This parameter does not affect initial connection retransmission.

MINIMUMRETRANSMITTIME

Sets a minimum retransmit interval. Increasing this value might increase the amount of time it takes for TCP to time out a connection. The minimum value that can be specified for MINIMUMRETRANSMITTIME is 0. The maximum is 99.990. The default is 0.5 (500 milliseconds).

ROUNDTRIPGAIN

This value is the percentage of the latest Round Trip Time (RTT) to be applied to the smoothed RTT average. The higher this value, the more influence the latest packet RTT has on the average. The minimum value that can be specified for ROUNDTRIPGAIN is 0. The maximum value is 1.0. The default is 0.125. This parameter does not affect initial connection retransmission.

VARIANCEGAIN

This value is the percentage of the latest RTT variance from the RTT average to be applied to the RTT variance average. The higher this value, the more influence the latest packet's RTT has on the variance average. The minimum value that can be specified for VARIANCEGAIN is 0. The maximum value is 1.0. The default is 0.25. This parameter does not affect initial connection retransmission.

VARIANCEMULTIPLIER

This value is multiplied against the RTT variance in calculating the retransmission interval. The higher this value, the more affect variation in RTT has on calculating the retransmission interval. The

minimum value that can be specified for VARIANCEMULTIPLIER is 0. The maximum value is 99.990. The default is 2. This parameter does not affect initial connection retransmission.

Retransmission parameters

Use the ROUNDTripGain, VARIANCEGain, and VARIANCEMULTIPLIER parameters to instruct TCP how heavily to weigh the most recent behavior of the network versus the long term behavior for updating the SRTT and VAR values. If you specify smaller values for these parameters, TCP attempts to correct for congestion only if the congestion is sustained. With larger values, TCP corrects for congestion more quickly, and the system is more sensitive to variations in network performance. Use the default values (unless your retransmission rate is too high).

Use DELAYACKS to delay the acknowledgments so that they can be combined with data sent to the foreign host.

Steps for modifying

To modify any values on the BEGINROUTES-ENDROUTES block, use a VARY TCPIP,,OBEYFILE command with a data set that contains a new BEGINROUTES-ENDROUTES block. All existing static routes are deleted, along with all routes learned by way of ICMP or ICMPv6 redirects. Routes created by OMPROUTE and router advertisements are not deleted. To remove all static routes from the main routing table, specify an empty BEGINROUTES-ENDROUTES block.

Results:

- If any HOME list entries are changed or deleted, all static routes using the associated links are deleted. This applies to IPv4 only.
- If any INTERFACE statements are deleted, all static routes that correspond with the INTERFACE names are deleted.
- If a LINK or INTERFACE becomes inactive, then all routes that are associated with that link or INTERFACE are marked inactive.
- If a LINK or INTERFACE becomes active, then all static routes that are associated with that link or INTERFACE are marked active.

Examples

```
; BEGINRoutes: Defines static routes to the main route table for IPv4
;               and IPv6
;
BEGINRoutes
;
; Direct Routes - Routes that are directly connected to my interfaces.
;
;       Destination Subnet Mask   First Hop   Link Name Packet Size
;
ROUTE 193.5.2.0/24                =           ETH1      MTU 1500
ROUTE 193.7.2.2   HOST            =           SNA1      MTU 2000
;
;       Destination Subnet Mask   First Hop   Interface  Packet Size
;
ROUTE fe80::230:71ff:fed3:5160  HOST =         OSAQDI026  MTU 2000
ROUTE 2001:0CD8:1/128            =         OSAQDI026  MTU 2000
;
; Indirect Routes - Routes that are reachable through routers on my
;                   network.
;
;       Destination Subnet Mask   First Hop   Link Name Packet Size
;
ROUTE 10.5.6.4   HOST            193.5.2.10  ETH1      MTU 1500
;
;       Destination Subnet Mask   First Hop   Interface  Packet Size
;
ROUTE FEC8::/64          fe80::230:71ff:fed3:5160  OSAQDI026  MTU 2000
;
; Default Route - All packets to an unknown destination are routed
```

```

;           through this route.
;
;           Destination          First Hop   Link Name Packet Size
; ROUTE DEFAULT                  193.5.2.99   ETH1      MTU DEFAULTSIZE
;
;           Destination Subnet Mask   First Hop   Interface   Packet Size
; ROUTE DEFAULT6                 fe80::230:71ff:fed3:5160   OSAQDI026   MTU DEFAULTSIZE
ENDRoutes

```

Usage notes

- The destination address and first hop IP address must both be either IPv4 or IPv6. If they do not match, an error message is displayed.
- An error message is displayed if an IPv6 address is coded along with an IPv4 link name, or if an IPv4 address is coded along with an IPv6 interface name.
- If the first hop IP address is IPv6, then it cannot be an IPv4-mapped IPv6 address (in hexadecimal or dotted decimal format) or an IP address with the reserved prefix `::/96`. If the IPv6 address is one of these types, an error message is displayed.
- If the destination address is an IPv4-mapped IPv6 address, an error message is displayed.
- The host portion of a valid host IP address cannot be all ones or all zeros; an address that consists of all ones or zeros is considered to be the broadcast address. The *dest_ipaddr* value can be either a network address or a host IP address. The *gateway_addr* value must be a host IP address.
- Packet size considerations:
 - The *mtu_size* value that z/OS Communications Server can handle varies for different networks. For example, while the largest packet size for the Ethernet protocol is 1500 bytes, the largest packet size for the 802.3 protocol is 1492 bytes.
 - The actual packet size is determined by the total network connection.
 - If a locally attached host has a packet size smaller than yours, transfers to that host use the smaller size.
 - The TCP maximum segment size for the 3172 Interconnect Controller Program is 4096. Any packet specifications over 4096 are limited by this restriction. For example, if you specified a packet size of 4352, the resulting packet size would still only be 4096 + the header = 4132.
 - Large packets can be fragmented by intervening gateways for IPv4 only. Fragmentation and reassembly of packets are expensive in their use of bandwidth and CPU time. Therefore, packets sent through gateways to other networks should use the default size, DEFAULTSIZE, unless one of the following situations is true:
 - All intervening gateways and networks are known to accept larger packets
 - Path MTU discovery (PATHMTUDISCOVERY) is enabled on the IPCONFIG statement, which results in the TCP/IP stack dynamically learning the maximum MTU for the total network connection. For IPv6, Path MTU discovery is always enabled.
 - If this is a pSeries link, the *mtu_size* value cannot exceed the *write_size* specified on the corresponding DEVICE statement.
 - You cannot specify an MTU smaller than the default MTU size. For IPv4 the default MTU is 576 and for IPv6 it is 1280.
- If the routing table is empty, all addresses in the HOME list remain route capable. For information about testing commands with LOOPBACK, see the z/OS Communications Server: IP User's Guide and Commands.
- The IPv4 *address_mask* value must follow the Classless Inter-Domain Routing (CIDR) convention that requires the actual mask to be one or more on-bits followed by zero or more off-bits. You cannot have on-bits followed by off-bits followed by on-bits. Therefore, a mask of 255.255.254.0 (or FFFFFFFE00) is valid, but a mask of 255.255.253.0 (or FFFFFFFD00) is not valid because 253 is 11111101.
- There is no limit on the number of equal-cost multipath routes to a destination.

- Multicast routes can be specified using host specification. You can also specify multicast network or prefix routes by using BEGINROUTES. A general multicast default route for IPv6 can be specified using:

```
BEGINROUTES
ROUTE FF00::/8 = INTERFACE1 MTU 4096
ENDROUTES
```

- Policy agent Route table, see “RouteTable statement” on page 1068

BSDROUTINGPARMS statement

Restriction: The BSDROUTINGPARMS statement applies only to IPv4 interfaces defined with the LINK statement.

Use the BSDROUTINGPARMS statement to define the characteristics of every physical link defined at the host. This includes links used for static routing.

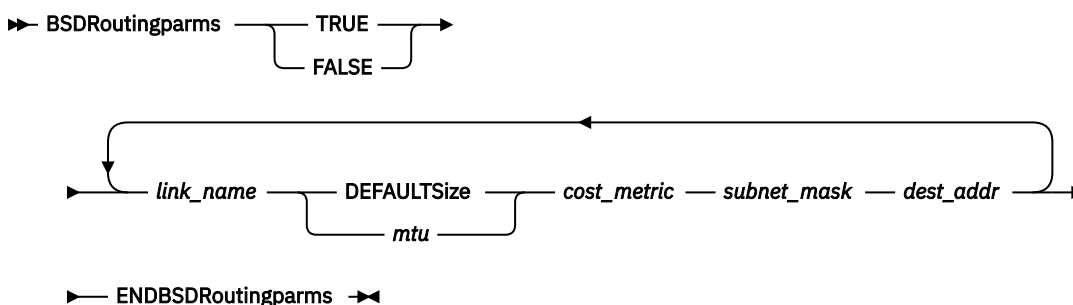

For more information about subnet masking, see [z/OS Communications Server: IP Configuration Guide](#).

When not using OMPROUTE, define links in BSDROUTINGPARMS. Otherwise, the values for MTU and subnet mask for links are filled in from BEGINROUTES statements, if any. These assumed definitions might not provide good performance or function.

If using OMPROUTE, it is not necessary to define the BSDROUTINGPARMS statement because the parameters are overridden by OMPROUTE. However, if the Ignore_Undefined_Interfaces option is defined in OMPROUTE such that a default interface definition is not generated for a corresponding link, BSDROUTINGPARMS might need to be defined to specify interface characteristics for that link. If OMPROUTE does not have the equivalent parameters coded for a corresponding link, it provides defaults that might not provide good performance or function.

Syntax

Rule: Specify the parameters in the order shown here.

Parameters

TRUE

Specifies that the maximum packet size for the interface is always used regardless of whether the destination is one or more hops away.

FALSE

Specifies that the default maximum packet size of 576 is used (rather than the packet size of the interface) when sending to networks that are not locally attached.

link_name

The name of the link as defined in a LINK statement.

Requirements:

- Each link must be defined once in the BSDROUTINGPARMS statement.
- To be used, a link must be defined at the time the BSDROUTINGPARMS statement is processed. If the corresponding link name is not defined in the HOME list, the link has no HOME address and is rendered as unusable until a HOME address is assigned.

mtu

The maximum packet size for this interface. The DEFAULTSIZE keyword can be used to designate the default of 576. The minimum value is 1, and the maximum value is 65 535.

See [Figure 1 on page 36](#) for more information about the largest MTU value supported by each link type.

The MTU value specified on BSDROUTINGPARMS statement is also used for applications that use the setsockopt() IP_MULTICAST_IF option to specify the route for multicast datagrams.

Tip: See *z/OS Communications Server: IP Configuration Guide*, section Maximum transmission unit considerations, for additional information about how TCP/IP uses the MTU to determine the largest size frame to send.

cost_metric

Specifies the interface-level metric associated with the cost of use for the link. If using OMROUTE, the value of *cost_metric* is overridden with a corresponding interface parameter value that might be coded or set (Cost0= on OSPF_INTERFACE or In_Metric= on RIP_INTERFACE). The default is 0.

subnet_mask

A bit mask (expressed in dotted decimal form), having bits in the network or host portions, that define the link-level subnet mask associated with the link and acts as a default for a route-level subnet mask to be used for routes dynamically created over this link.

Requirement: The bits must be contiguous from left to right.

The *subnet_mask* is related to the HOME IP address of the link. If the *subnet_mask* equals 0 to indicate that the network is not subnetted, the default is the network class mask, which is based on an IP address class. By definition, the network class masks are:

- Class A: 255.0.0.0
- Class B: 255.255.0.0
- Class C: 255.255.255.0

A subnet mask is used in calculation of a subnet, network, or supernet route. A subnet route is used to represent multiple hosts in a subnet, a network route is used to represent multiple subnet routes (or multiple hosts if the network is not subnetted), and a supernet route is used to represent multiple network routes in a supernet. For Classless Inter-Domain Routing (CIDR) support, variable-length subnet masks can be used. Variable-length subnet masks can be used in a single network; that is, multiple subnets having the same network number can have different subnet masks. Fixed-length subnet masks are used in a single network with multiple subnets having the same network number and subnet mask. A subnet mask that is less than the network class mask is considered to be a supernet mask. A supernet mask can be defined such that multiple networks can be represented by a single supernet.

Restriction: The host mask of 255.255.255.255 cannot be used for the interface-level subnet mask; however, an implicit host route based on its home IP address is dynamically created internally for this link.

dest_addr

Destination address applies to point-to-point links only. A nonzero destination address applies to nonbroadcast-capable and nonmulticast-capable point-to-point links. If 0 is coded, a directed broadcast or multicast address is used; otherwise, insert the address of the host on the other end of the link. For VIPA links, this field should be 0.

See [Figure 1 on page 36](#) for more descriptions about devices and links.

Steps for modifying

To modify the BSDROUTINGPARMS statement for a link, use a VARY TCPIP,,OBEYFILE command with a data set which defines a new BSDROUTINGPARMS statement for a link with the same *link_name*. The new BSDROUTINGPARMS statement is a complete replacement for the original BSDROUTINGPARMS statement. If you have changed the link's IP address, or the order of the HOME list entries, along with the BSDROUTINGPARMS changes, remember to include the new HOME list statement in the same VARY TCPIP,,OBEYFILE command data set as the new BSDROUTINGPARMS statement.

For more information about [VARY TCPIP Command](#), see [z/OS Communications Server: IP System Administrator's Commands](#).

Table 3. BSDROUTINGPARMS modification methods	
Modification method	Required action
Adding new links	Issue VARY TCPIP,,OBEYFILE command with new DEVICE, LINK, HOME, and BSDROUTINGPARMS statements.
Deleting or changing order of links in use.	Issue VARY TCPIP,,OBEYFILE command with new HOME statement.
Changing HOME IP addresses or BSDROUTINGPARMS values for existing links in use.	Issue VARY TCPIP,,OBEYFILE command with new HOME statements or BSDROUTINGPARMS statements, or both.
Guideline: If HOME addresses have been changed, the NCP generation definitions must also be changed in order to recognize the new HOME addresses.	

Examples

This example shows the BSDROUTINGPARMS statement for an Ethernet interface.

```
; link      maxmtu  metric  subnet mask  dest addr
BSDROUTINGPARMS false
  ETH1      1500    0      255.255.255.0  0
ENDBSDROUTINGPARMS
```

This example includes a link, LINK3, that is a point-to-point link between host MVS1 and host 128.84.54.6.

```
;
; link      maxmtu  metric  subnet_mask  dest_addr
BSDROUTINGPARMS false
  LINK1     DEFAULTSIZE  0      255.255.255.0  0
  LINK2     DEFAULTSIZE  0      255.255.255.0  0
  LINK3     1500        0      255.255.255.0  128.84.54.6
ENDBSDROUTINGPARMS
```

This example shows the definitions for VIPA links.

```
BSDROUTINGPARMS false
  VLINK1     DEFAULTSIZE  0  255.255.255.252  0
```

```

VLINK2  DEFAULTSIZE 0 255.255.255.252 0
ENDBSDROUTINGPARMS

```

This example shows how BSDRoutingparms relate to other statements in the profile.

```

DEVICE DEVC00 CTC C00 IOBUFFERSIZE 65535 AUTORESTART
LINK LCTCC00 0 DEVC00 IFSPEED 10000
HOME 9.32.2.1 LCTCC00
PRIMARYINTERFACE LCTCC00
BSDROUTINGPARMS TRUE
LCTCC00 DEFAULTSIZE 0 255.252.0.0 9.32.2.5
ENDBSDROUTINGPARMS
START DEVC00

```

This example shows how to use BSDRoutingparms with supernet routes.

```

HOME
130.201.1.1 VLINK1
172.200.10.1 ETH1
192.3.200.1 CTCBF0

BSDROUTINGPARMS FALSE
ETH1 1500 0 255.252.0.0 0
VLINK1 1500 0 255.254.0.0 0
CTCBF0 1000 0 255.255.252.0 192.3.200.2
ENDBSDROUTINGPARMS

```

Usage notes

- For rules on defining virtual IP addresses for VIPA links, see [“HOME statement” on page 76](#).
- The maximum transmission unit (MTU) and metric of any other links with a destination address in the same subnet are updated to ensure that all entries in the same subnet have the same routing values. Except for these links and the LOOPBACK link, all links get default BSD values if not specified.
- If no HOME address exists for a LINK or if a HOME address is changed by way of a later VARY TCPIP,,OBEYFILE command, processing of the HOME statement verifies whether *subnet_mask* value on the BSDROUTINGPARMS statement is within the valid ranges.
- When an incorrect BSDROUTINGPARMS entry is encountered, all entries following that entry on that BSDROUTINGPARMS statement are ignored. Subsequent BSDROUTINGPARMS statements are processed.
- BSDROUTINGPARMS statements can only be coded for LINK names that exist in the HOME list when the statement is processed. Thus, LINKs from IPCONFIG DYNAMICXCF and the VIPADYNAMIC block should not be included in BSDROUTINGPARMS statements of the initial PROFILE.TCPIP. However, the data set used on a VARY TCPIP,,OBEYFILE command can contain BSDROUTINGPARMS statements with LINKs from IPCONFIG DYNAMICXCF and the VIPADYNAMIC block.
- The BSDROUTINGPARMS parameter values are displayed with the Netstat DEvlinks/-d commands. If the BSDROUTINGPARMS statement is not defined, the values of the displayed parameters are either the defaults from the BEGINROUTES statement, or are from the OMPROUTE configuration statements.

Related topics

- [“BEGINROUTES statement” on page 19](#)

DEFADDRTABLE statement

Use the DEFADDRTABLE statement to configure the policy table for IPv6 default address selection. If you do not configure the policy table for IPv6 default address selection with the DEFADDRTABLE profile statement, then the following default policy table is used:

Prefix	Precedence	Label
::1/128	50	0
::/0	40	1
2002::/16	30	2
::/96	20	3
::ffff:0.0.0.0/96	10	4

Restriction: Only one DEFADDRTABLE block should appear in a configuration data set. Any subsequent DEFADDRTABLE blocks are ignored, and an informational message is displayed. If a syntax error is encountered when this statement is processed, an error message is displayed, and the entire DEFADDRTABLE block is ignored (no entries are processed).

Guideline: The order of the entries in the policy table is not important. When the policy table is used during address selection, all entries in the table are searched to locate the entry with the prefix that best matches (longest prefix match) the address for which precedence and label values are needed.

For more information about the policy table for default address selection and the precedence and label values, see [z/OS Communications Server: IPv6 Network and Appl Design Guide](#).

Syntax

Policy Entry

Parameters

prefix/prefix_length

The address prefix that is used to select the policy table entry that best matches a source address or a destination address. The policy table is a longest-matching-prefix lookup table.

If duplicate prefix entries are specified in the same DEFADDRTABLE block, the first prefix entry is used, the remaining duplicate prefix entries are ignored, and messages are displayed.

prefix

The digits (in colon-hexadecimal format) before the slash (/) specify the prefix.

prefix_length

An integer value in the range 0 - 128 that specifies the length of the prefix, in bits.

precedence

An integer value in the range 0 - 65530 that specifies the precedence that is used to sort destination addresses.

label

An integer value in the range 0 - 65530 that specifies that a particular source address prefix is preferred for use with a destination address prefix.

Steps for modifying

The following considerations apply when you modify the DEFADDRTABLE block:

- To remove all the current configured policies, specify the DEFADDRTABLE block without any entries:

```
DEFADDRTABLE ENDEFADDRTABLE
```

Issue the VARY TCPIP,,OBEYFILE command; the default policy table replaces the previously configured values.

- To change any of the policy entries, create a DEFADDRTABLE block with the existing set of policies. Update the policy entries that need to be changed. Then, issue the VARY TCPIP,,OBEYFILE command to activate the change. The new policy table completely replaces the existing policy table.

Examples

The default policy table contains the following values:

```
DEFADDRTABLE
; Prefix          Precedence Label
  ::1/128          50           0
  ::/0             40           1
  2002::/16        30           2
  ::/96            20           3
  ::ffff:0.0.0.0/96 10           4
ENDEFADDRTABLE
```

This default table specifies the following behavior:

- Prefer using native source addresses with native destination addresses, 6to4 source addresses with 6to4 destination addresses, and IPv4-compatible source addresses with IPv4-compatible destination addresses

Guideline: IPv4-compatible addresses have been deprecated by RFC 4291, but are shown here because they are part of the default policy table defined by RFC 3484.

- Prefer using IPv6 network transport over IPv4 network transport when possible

To specify that IPv4 network transport should be preferred over IPv6 network transport, change the precedence of the ::ffff:0.0.0.0/96 prefix to 100.

```
DEFADDRTABLE
; Prefix          Precedence Label
  ::1/128          50           0
  ::/0             40           1
  2002::/16        30           2
  ::/96            20           3
  ::ffff:0.0.0.0/96 100          4
ENDEFADDRTABLE
```

All other considerations being equal, a destination address whose label does not match the label of any of the possible source addresses prefers an IPv4 source address because the precedence value for the ::ffff:0.0.0.0/96 prefix is higher than the precedence value of all the other entries.

The destination address selection rules give preference to destinations of smaller scope. For example, a link-local destination is sorted before a global scope destination when the two are otherwise equally suitable. To sort global destinations before link-local destinations, change the policy table to reverse the existing preference.

```
DEFADDRTABLE
; Prefix          Precedence Label
  ::1/128          50           0
  ::/0             40           1
  fe80::/10        33           1
  2002::/16        30           2
  ::/96            20           3
  ::ffff:0.0.0.0/96 100          4
ENDEFADDRTABLE
```

DELETE statement

Use the DELETE statement to delete a previously defined DEVICE, LINK, PORT, or PORTRANGE.

Guideline: Use the INTERFACE statement with the DELETE parameter to delete a previously defined interface.

Syntax

Rule: Specify the parameters in the order shown here.

➤ DELETE — DEVICE — *device_name* ➤

➤ DELETE — LINK — *link_name* ➤

➤ DELETE — PORT ➤

Port Options

The optional parameters for the PORT profile statement can be specified on the DELETE PORT statement but, though the syntax of the parameters is verified, the parameter values are ignored.

➤ DELETE — PORTRange ➤

Portrange Options

The optional parameters for the PORTRANGE profile statement can be specified on the DELETE PORTRANGE statement but, though the syntax of the parameters is verified, the parameter values are ignored.

Parameters

The values of the required parameters must match the existing reservation or the delete fails. You can specify the optional parameters for the PORT or PORTRANGE profile statement on the DELETE PORT or DELETE PORTRANGE statement. However, even though the syntax of the parameters is verified, the parameter values are ignored.

The following parameters are network interface parameters:

device_name

The name of the device to be deleted. This is the name that was used on a DEVICE statement to define the device to TCP/IP.

link_name

The name of the link to be deleted. This is the name that was used on a LINK statement to define the link to TCP/IP.

The following parameters are PORT and PORTRANGE parameters.

To delete an existing PORT or PORTRANGE reservation, use a PORT or PORTRANGE profile statement and prefix it with the DELETE keyword. The only required parameters on the DELETE PORT or DELETE PORTRANGE statement are as follows:

- Reserved port number or UNRSV on the DELETE PORT statement, or the range of port numbers on the DELETE PORTRANGE statement
- Protocol of TCP or UDP
- Job name specification

num

The port number of the port to be deleted. This is the port number that was used on a PORT statement to define the port to TCP/IP.

UNRSV

UNRSV indicates that a statement that defines access to unreserved port numbers is to be deleted.

1st_port

The first port number in the range of reserved ports to be deleted.

num_ports

The number of ports to be deleted, starting with the port specified on the *1st_port* parameter. This range is the same number of ports that were reserved when the port range was defined with the PORTRANGE statement.

jobname

The job name associated with the port to be deleted.

RESERVED

Indicates that the port is not available for use by any user. Use this value to lock certain ports. This value is optional and valid for TCP and UDP protocols.

AUTHPORT

Indicates that the port is not available for use by any user except FTP, and only when FTP is configured to use PASSIVEDATAPORTS. AUTHPORT is valid only with the TCP protocol.

Steps for modifying

Modification is not applicable to this statement.

Statement dependency

- To delete a link, you must first delete any associated HOME entry by specifying a HOME statement that does not include the link, and you must also stop the device.

Restriction: You do not need to (and cannot) stop the device when deleting a link for a virtual device.

- To delete a device, you must first stop the device, then delete all associated links.

Restriction: You do not need to (and cannot) stop the device when deleting a link for a virtual device.

Examples

This example shows DELETE statements that delete a link called sanjose and a device called ourctc:

```
DELETE LINK sanjose
DELETE DEVICE ourctc
```

This example shows a DELETE PORT statement that deletes a reservation for port 5001:

```
PORT 5001 TCP MEGA
DELETE PORT 5001 TCP MEGA
```

This example shows a PORT statement that denies all jobs access to unreserved UDP ports on explicit binds. The example also shows the DELETE PORT statement that deletes this access restriction.

```
PORT UNRSV UDP * DENY WHENBIND
DELETE PORT UNRSV UDP *
```

The keywords DENY and WHENBIND are not required on the DELETE PORT statement.

This example shows several PORTRANGE statements to reserve ports for MEGA, and then several DELETE PORTRANGE statements to delete the reservations for those ports:

```
PORTRANGE 5000 10 UDP MEGA
          5100 10 TCP MEGA NOAUTOLOG
          5200 10 UDP MEGA DELAYACKS
          5300 10 TCP MEGA
          5400 10 UDP MEGA
          5500 10 TCP MEGA NOAUTOLOG DELAYACKS
DELETE PORTRANGE
          5000 10 UDP MEGA
          5100 10 TCP MEGA NOAUTOLOG
          5200 10 UDP MEGA DELAYACKS
          5300 10 TCP MEGA
          5400 10 UDP MEGA
          5500 10 TCP MEGA NOAUTOLOG DELAYACKS
```

Usage notes

The *link_name* of a deleted link remains associated with its device. It cannot be reassigned to a new device while TCP/IP is active.

Summary of DEVICE and LINK statements

Restriction: The DEVICE and LINK statements apply to IPv4 only.

To define an IPv6 interface, you must use the INTERFACE statement. You can also use the INTERFACE statement to define an IPv4 interface for OSA QDIO Ethernet, HiperSockets, and static VIPA. See [“Summary of INTERFACE statements” on page 80](#) for more information.

Overview of DEVICE and LINK statements

z/OS Communications Server allows a single TCP/IP address space to drive multiple instances of any supported device. To configure your devices, add the appropriate DEVICE and LINK statements to the configuration data set. The LINK statements show how to define a network interface link associated with the device and are included with the DEVICE statement for that device type.

Requirements: The following list shows the minimum required statements to define a network interface for use by TCP/IP:

- A set of DEVICE and LINK statements for the appropriate device. Depending on the type of device being defined, additional PROFILE statements, VTAM definitions, or both might be required. For more details, see the DEVICE and LINK statements for the device type.
- A HOME statement assigning an IP address to the LINK interface. For more details, see [“HOME statement” on page 76](#).
- If you use static routing, define a BEGINROUTES statement that references the LINK interface to reach the target networks. For more details, see [“BEGINROUTES statement” on page 19](#).
- If you use dynamic routing, see [Chapter 11, “OMPROUTE,” on page 429](#).

Because devices (except VIPA devices) are not automatically initialized, you must also specify a START statement in the configuration data set to start each device automatically.

Restrictions:

- Because TCP/IP has a maximum of 255 started devices (not including VIPA), you cannot start more than 255 devices.

- If you use OMPROUTE, the maximum number of non-VIPA links that can be specified in the HOME list is 255.
- There is no maximum for static VIPA interfaces, but the maximum number of dynamic VIPA interfaces is 1024.

Figure 1 on page 36 summarizes information about the various IPv4 network interfaces supported by TCP/IP. The values listed in the MTU column represent the largest MTU supported by each interface.

Device	Link type	Connectivity	ID in TCP/IP profile	ARP	ARP resolution	MTU (B)	QDIO	Multiple links	TRLE definition	Multiple support	Broadcast support	Point-to-point	Dynamic VOF support	64-bit support (68)
CTC	CTC	z/OS using channel-to-channel adapter	Device number	No	No	65527 (64)	No	No	Generated by VTAM	Yes	No	Yes (P1)	No	Compatibility
MPQDTP	MPQDTP	z/OS R84000 Cisco CIP, R84000, CCNT, or CEM	TRUE name	No	No	90102 (44)	No	No	Reserved	Yes	No	Yes (P1)	No	Compatibility
MPQDTP for KDC	MPQDTP	Another TCP/IP within same z/OS system	CP name of target VTAM	No	No	90106	No	No	Generated by VTAM	Yes	No	Yes (P1)	Yes	Compatibility
MPQDTP for UTWAND	MPQDTP	Another TCP/IP on external VOF for VTAM for CEM or CEM	UTWAND	No	No	90115	No	No	Reserved name	Yes	No	Yes (P1)	Yes	Compatibility
MPQDTP for R84000	R84000	Another TCP/IP within the same CIP	UTWAND	No	Yes (Local Binding)	90144 (48)	Yes	No	Reserved name	Yes	Yes (P1)	No	Yes	Exploitation

Figure 1. Summary of DEVICE and LINK statements

Notes:

1. Can be point-to-multipoint.
2. The MTU column represents the largest MTU supported by the interface.
3. Based on the IOBUFFERSIZE value on the CTC device statement in TCP/IP profile.
4. Based on MAXBFRU value in the TRLE definition.
5. Based on frame size configured in HCD.
6. Requires IPBCAST parameter on LINK statement in TCP/IP profile.
7. The TCP/IP stack exploits 64-bit virtual storage. TCP/IP device drivers have two levels of 64-bit support:
 - 64-bit compatibility means that the device does not exploit 64-bit virtual storage but is compatible with the 64-bit TCP/IP stack. Additional copies of incoming and outgoing data between stack 64-bit virtual storage and device driver 64-bit virtual storage might be required. This might affect CPU and performance. The impact, if any, is based on the characteristics of your specific workloads such as message size and patterns, and environment. This is primarily an issue for streaming or bulk workloads.
 - 64-bit exploitation means that the device fully exploits 64-bit virtual storage and does not require additional copies between stack 64-bit virtual storage and device driver 64-bit virtual storage.

Recovering from device failures

TCP/IP automatically attempts reactivation of the non-VIPA device following some device-failure indications (regardless of the AUTORESTART setting). Specifying AUTORESTART causes TCP/IP to attempt reactivation following most device-failure indications.

The AUTORESTART option is meaningful only for errors that occur after the device is active. For errors that occur before the device reaches the active state, AUTORESTART has no effect, as such errors might likely be the result of a configuration error (for example, incorrect device number specification within the TCP/IP PROFILE). No automatic error correction would be possible for such an error, and for this reason, TCP/IP initiates device recovery only when evidence of a previously working configuration exists. For any error encountered before the device reaches the active state, the user should correct any configuration error and initiate a new START DEVICE.

If automatic reactivation is attempted, the number of allowable reactivation attempts is determined from the IPCONFIG DEVRETRYDURATION setting.

DEVRETRYDURATION specifies the duration of the Retry Period, during which TCP/IP attempts automatic recovery of a device. The first reactivation attempt is performed two seconds after the original error, and subsequent attempts are 30 seconds apart. If not successfully reactivated within the specified retry

duration, the device is returned to the INACTIVE state, and a manual START of the device is required after the error has been corrected.

Missing interrupt handler factors

When multiple subchannels are used for channel-layer communications, WRITE operations and READ operations are separated onto their own subchannels. On a multi-subchannel device, the missing interrupt handler (MIH) is automatically (by VTAM) configured OFF on the READ subchannels. (This is necessary, as a READ command is always active for such devices, and MIH would detect a missing interrupt on the READ subchannels any time the device experienced an idle period.) Therefore, there is no need to specify any MIH values for TCP/IP read devices.

VTAM honors the MIH provided for MPCPTP and MPCPTP6 write devices, but imposes a limit of four minutes and fifteen seconds. If a value is not provided, VTAM uses a value of 30 seconds, unless running as a guest on VM in which case, a value of 45 seconds is used. For other device types, an MIH value of 0, which disables MIH, for a TCP/IP write device or a single-subchannel device is *not* advisable.

You should configure a reasonable MIH value for the WRITE subchannels on a multi-subchannel device. This configuration protects the system from a storage-usage spike, which a hung device brings on.

Reasonable values for MIH on the WRITE subchannel in the range 15-30 seconds [a value of 30 seconds might be warranted if either channel extenders are in the configuration, or dispatching delays (due to running second level, under VM) are possible]. For nonextended ESCON channels, being driven by z/OS running native, 15 seconds is the preferred MIH value.

In summary, MIH on the WRITE subchannels should be configured ON, with a value in the range 15 - 30 seconds for the following TCP/IP device types:

- For MPCPTP, the write subchannels are specified on the WRITE parameter of the TRLE definition.
- For MPCIPA, the WRITE-control subchannel is specified on the WRITE parameter of the TRLE definition.

Tip: To override the default MIH value for a given subchannel, use the MIH statement in the IECIOSxx parmlib member or use the SETIOS MIH command. See [z/OS MVS System Commands and z/OS MVS Initialization and Tuning Guide](#) for more information about the IECIOSxx parmlib and SETIOS command, respectively.

Restriction: For all other TCP/IP device types (including the XCF and IUTSAMEH types of MPCPTP and the data devices for MPCIPA), MIH is either not applicable or is automatically disabled by VTAM.

DEVICE and LINK statements relationship to VTAM configuration

z/OS Communications Server provides a set of High Performance Data Transfer (HPDT) services that includes MultiPath Channel (MPC), a high-speed channel interface designed for network protocol use (for example, APPN or TCP/IP). Multiple protocols can either share or have exclusive use of a set of channel paths to an attached platform. The term *MPC+* is used to distinguish this multi-protocol version of MPC from earlier versions that were restricted to APPN usage only.

MPC provides the user with the ability to have multiple device paths defined as a single logical connection. The term *MPC group* is used to define a single MPC connection that can contain multiple read and write paths. The number of read and write paths do not have to be equal, but there must be at least one read and write path defined within each MPC group.

MPC groups are defined using the Transport Resource List (TRL), where each defined MPC group becomes an entry (that is, a TRLE) in the TRL table. The user defines the channel paths that are a part of the group in the TRLE. Each TRLE is identified by a *resource_name*. For details about defining a TRLE, see the [z/OS Communications Server: SNA Resource Definition Reference](#).

Modifying DEVICE and LINK statements

To modify most LINK statement parameters and any DEVICE statement parameters, you must first delete and then redefine the LINK or DEVICE statement.

However, the following LINK statement parameters are dynamically modifiable:

- MONSYSPLEX
- NOMONSYSPLEX

To modify these parameters on a LINK statement, use a VARY TCPIP,,OBEYFILE command with a data set that contains a LINK statement for an existing link name which has new values for these parameters.

Guidelines:

- Any changes to non-modifiable parameters are ignored.
- If any modifiable parameters are not specified, prior values remain in effect for these parameters.

Steps for modifying DEVICE and LINK statements

Complete the following steps to modify all other parameters on a LINK statement or to modify any DEVICE statement parameters.

Procedure

1. Stop the device.

Ignore this step if the device is for a static VIPA because it cannot be stopped.

2. Use a VARY TCPIP,,OBEYFILE command with a data set that contains the following items:

- A new HOME statement that does not contain the home IP address or addresses of the link or links to be deleted
- DELETE linkname and DELETE devicename statements

Result: The stack deletes all static routes that reference the name of the deleted link.

For more information about [VARY TCPIP Command](#), see [z/OS Communications Server: IP System Administrator's Commands](#).

3. Use a VARY TCPIP,,OBEYFILE command with a data set that contains the following items:

- The changed DEVICE and LINK statements
- A new HOME statement that includes the home IP address or addresses of the link or links to be added

If you were using static routes that referenced the name of the deleted link, this data set should also contain a BEGINROUTES block with your complete set of static route definitions.

The data set that is used on the VARY TCPIP,,OBEYFILE command in this step must be different from the data set that is used in step 2. Do not put the deletion and redefinition of an interface in the same OBEYFILE data set.

4. Start the device.

Ignore this step if the device is for a static VIPA. A static VIPA becomes active after its IP address is added to the HOME list in step 3.

Guidelines:

- To change parameters or dynamically change a value on a LINK statement only, you do not need to delete and later redefine the DEVICE name statement.
- When you add LINK statements, any corresponding BEGINROUTES, HOME, and TRANSLATE statements coded to include the new links are treated as replacements for active statements. Therefore, when you code the BEGINROUTES, HOME, or TRANSLATE statements of the data set specified on a VARY TCPIP,,OBEYFILE command, be sure to include new and existing links that you want to have active in your configuration.

Monitoring network links (DEVICE and LINK statements)

To delete links, the devices must be stopped. When the devices are stopped, the link becomes inactive. If the TCP/IP stack is currently monitoring interfaces and detects that all monitored interfaces are inactive as a result of the devices being stopped, the TCP/IP stack might issue messages about the problem and might trigger a recovery action. You can disable monitoring of these interfaces. To do this, specify the NOMONSYNPLEX keyword on the LINK statement using the VARY TCPIP,,OBEYFILE command before stopping the devices. For more information, see [sysplex problem detection and recovery in z/OS Communications Server: IP Configuration Guide](#).

DEVICE and LINK - CTC devices statement

Use the DEVICE statement to specify the name and hexadecimal device number of the channel-to-channel (CTC) devices that you use. Use the LINK statement to define a network interface link associated with the CTC devices.

Requirement: You must use a separate DEVICE statement for each device you use. The same is true for the LINK statement.

For more information about missing interrupt handler (MIH) considerations with TCP/IP devices, see [“Missing interrupt handler factors” on page 37](#).

Syntax

Rule: Specify the parameters in the order shown here.

Parameter

device_name

The name of the device. The maximum length is 16 characters. The same name is specified in the LINK statement.

CTC

Specifies the device is a channel-to-channel (CTC) device.

base_device_number

The hexadecimal base device number associated with the CTC adapter. Two numbers are used by TCP/IP: the *base_device_number* and *base_device_number+1*.

IOBUFFERSIZE buffer_size

Specifies the I/O buffer size. The buffer size must be 32K (minimum), 32 768 (default), or 65 535 (maximum).

AUTORESTART | NOAUTORESTART

Controls device failure reactivation behavior.

NOAUTORESTART

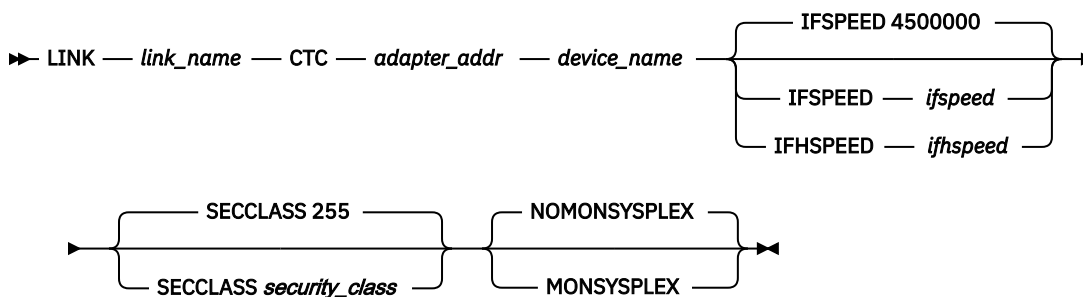

For most device failures, specifying NOAUTORESTART indicates that the TCP/IP address space does not attempt to reactivate this device.

AUTORESTART

In the event of a device failure, the TCP/IP address space attempts to reactivate the device. For more information, see [“Recovering from device failures” on page 36](#).

Syntax

Rule: The optional parameters on the LINK statement following the *device_name* parameter can be specified in any order.

Parameter

link_name

The name of the link. The maximum length is 16 characters.

CTC

Specifies that the link is a channel-to-channel link.

adapter_addr

An integer used to specify whether the DEVICE statement's parameter, *base_device_number*, is the read device number or the write device number. Use 0 to indicate that the base device number is the read device and 1 to indicate that the *base_device_number* is the write device.

device_name

The *device_name* must be the same as specified in the DEVICE statement.

IFSPEED *ifspeed*

An optional estimate of the interface's current bandwidth in bits per second. The minimum value that can be specified for *ifspeed* for a CTC link is 0; the maximum value is 2 147 483 647. The default is 4 500 000. This value is accessible to SNMP for management queries, but has no effect on operation of the device.

IFHSPEED *ifhspeed*

An optional estimate of the interface's current bandwidth in one million bits per second units. The minimum value that can be specified for *ifhspeed* for a CTC link is 0; the maximum value is 2147. The default is 4. This value is accessible to SNMP for management queries, but has no effect on operation of the device.

SECCLASS *security_class*

Use this parameter to associate a security class for IP filtering with this interface. In order for traffic over the interface to match a filter rule, the filter rule must have the same security class value as the interface or a value of 0. Filter rules can be specified in the TCP/IP profile or in an IP Security policy file read by the Policy Agent. Filter rules can include a security class specification on the IpService statement in an IP Security policy file or on the SECCLASS parameter on the IPSEC statement in the TCP/IP profile.

Valid security classes are identified as a number in the range 1 - 255. The default value is 255.

For more information about [security class values](#), see [z/OS Communications Server: IP Configuration Guide](#).

Restriction: The TCP/IP stack ignores this value if IPSECURITY is not specified on the IPCONFIG statement.

MONSYSPLEX | NOMONSYSPLEX

Specifies whether or not sysplex autonomics should monitor the link's status.

NOMONSYSPLEX

Specifies that sysplex autonomics should not monitor the link's status. This is the default value.

MONSYSPLEX

Specifies that sysplex autonomics should monitor the link's status.

Restriction: The MONSYSPLEX attribute is not in effect unless the MONINTERFACE keyword is specified on the GLOBALCONFIG SYSPLEXMONITOR profile statement. The presence of dynamic routes over this link is monitored if the DYNROUTE keyword is also specified on the GLOBALCONFIG SYSPLEXMONITOR profile statement.

Steps for modifying

See [“Modifying DEVICE and LINK statements” on page 37](#) for modifying information.

Usage notes

The configured I/O buffer sizes at each end of the CTC connection must match. A buffer size mismatch can cause packet loss or I/O errors, resulting in deactivation of the CTC connection. CTC I/O buffer size can be explicitly specified with the IOBUFFERSIZE parameter.

DEVICE and LINK - MPCIPA HiperSockets devices statement

When defining an MPCIPA HiperSockets device, also known as an IQDIO device, use the DEVICE statement to specify the IQD CHPID hexadecimal value. The reserved device name using prefix IUTIQDxx must be specified. The suffix xx indicates the hexadecimal value of the corresponding IQD CHPID that was configured within HCD.

The hexadecimal value specified here cannot be the same value that is used for the dynamic XCF HiperSockets interface. See the IQDCHPID start option in [z/OS Communications Server: SNA Resource Definition Reference](#).

MPCIPA HiperSockets devices do not require a corresponding TRLE. Instead, the TRLE is dynamically built when the device is started. There is no PORT name used for HiperSockets MPCIPA devices. The NONROUTER, PRIROUTER, and SECROUTER parameters do not apply to a HiperSockets device and are ignored if specified on the MPCIPA statement.

Use the LINK statement to define a network interface link associated with the HiperSockets interface.

Restriction: Only one LINK statement can be specified for each MPCIPA HiperSockets device.

Tip: You can also use the INTERFACE statement to define an IPv4 interface for HiperSockets, which combines the definitions of the DEVICE, LINK, and HOME statements into a single statement.

To determine the HiperSockets microcode level, use the DISPLAY TRL command. If a specific HiperSockets function is documented with a minimum microcode level, you can use this command to determine whether that function is supported. IBM service might request the microcode level for problem diagnosis. For more information, see [DISPLAY TRL command in z/OS Communications Server: SNA Operation](#).

Syntax

Rule: Specify the parameters in the order shown here.

Parameter

device_name

The name of the device must use the following convention:

- Prefix is IUTIQD.
- Suffix xx [hexadecimal value (00x - FFx) of the corresponding IQD CHPID]. This value cannot conflict with the IQD CHPID used for dynamic XCF.

MPCIPA

Specifies the device belongs to the MPC family of interfaces and uses the interface based on IP assist.

AUTORESTART | NOAUTORESTART

Controls device failure reactivation behavior.

NOAUTORESTART

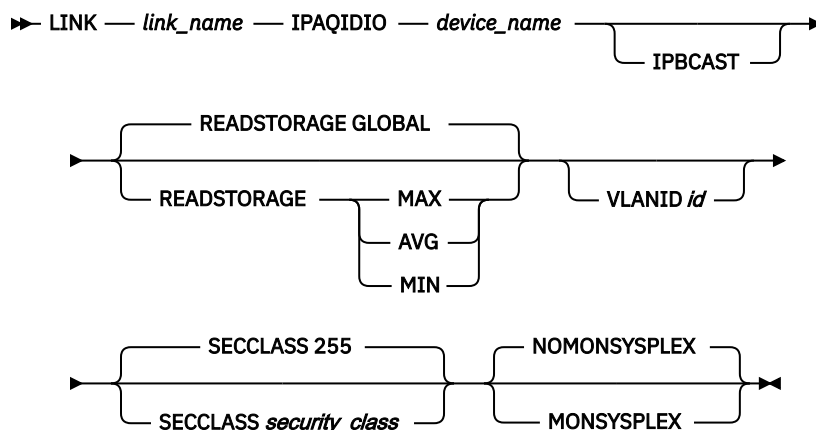

For most device failures, specifying **NOAUTORESTART** indicates that the TCP/IP address space does not attempt to reactivate this device.

AUTORESTART

In the event of a device failure, the TCP/IP address space attempts to reactivate the device. For more information, see [“Recovering from device failures” on page 36](#).

Syntax

Rule: The optional parameters on the LINK statement following *device_name* can be specified in any order.

Parameter

link_name

The name of the link. The maximum length is 16 characters.

IPAQIDIO

Indicates that the link uses the interface based on IP assist, belongs to the QDIO family of interfaces, and uses the HiperSockets protocol.

device_name

The *device_name* must be the same as specified in the **DEVICE** statement.

IPBCAST

Specifies that the link both sends and receives IP broadcast packets. If this parameter is not specified, no IP broadcast packets are sent or received on this link.

READSTORAGE

An optional parameter indicating the amount of fixed storage that z/OS Communications Server should keep available for read processing for this device. The IQDIOSTG VTAM start option allows you to specify a value which applies to all HiperSockets devices. You can use the READSTORAGE keyword to override the global IQDIOSTG value for this adapter based on the inbound workload you expect over this device on this stack. The valid values are:

GLOBAL

The amount of storage is determined by the IQDIOSTG VTAM start option. This is the default value.

MAX

Use this value if you expect a heavy inbound workload over this device.

AVG

Use this value if you expect a medium inbound workload over this device.

MIN

Use this value if you expect a light inbound workload over this device.

Tip: See the description of the IQDIOSTG VTAM start option in the [z/OS Communications Server: SNA Resource Definition Reference](#) for details about exactly how much storage is allocated by z/OS Communications Server for each of these values.

Restriction: This parameter only takes effect when the IQD frame size is 64K.

Rule: If you define both a LINK and INTERFACE statement for the same device, then the READSTORAGE value on the LINK statement must match the READSTORAGE value on the corresponding INTERFACE statement. If you define a LINK statement that contains a value for READSTORAGE that conflicts with the READSTORAGE value for a previous INTERFACE statement for the same device, then TCP/IP rejects the LINK statement.

VLANID *id*

An optional parameter followed by a decimal number indicating the virtual LAN identifier to be assigned to this HiperSockets link. The valid range is 1 - 4094.

Restriction: With HiperSockets, a stack can specify only one VLAN ID when the interface is used for both IPv4 and IPv6. If you specify a different VLAN ID value on a LINK and INTERFACE definition for the same CHPID, the second statement is rejected.

SECCLASS *security_class*

Use this parameter to associate a security class for IP filtering with this interface. In order for traffic over the interface to match a filter rule, the filter rule must have the same security class value as the interface or a value of 0. Filter rules can be specified in the TCP/IP profile or in an IP Security policy file read by the Policy Agent. Filter rules can include a security class specification on the IpService statement in an IP Security policy file or on the SECCLASS parameter on the IPSEC statement in the TCP/IP profile.

Valid security classes are identified as a number in the range 1 - 255. The default value is 255. For more information about [security class values](#), see [z/OS Communications Server: IP Configuration Guide](#).

Restriction: The TCP/IP stack ignores this value if IPSECURITY is not specified on the IPCONFIG statement.

MONSYSPLEX | NOMONSYSPLEX

Specifies whether or not sysplex autonomics should monitor the link's status.

NOMONSYSPLEX

Specifies that sysplex autonomics should not monitor the link's status. This is the default value.

MONSYSPLEX

Specifies that sysplex autonomics should monitor the link's status.

Restriction: The MONSYSPLEX attribute is not in effect unless the MONINTERFACE keyword is specified on the GLOBALCONFIG SYSPLEXMONITOR profile statement. The presence of

dynamic routes over this link is monitored if the DYNROUTE keyword is also specified on the GLOBALCONFIG SYSPLEXMONITOR profile statement.

Steps for modifying

See [“Modifying DEVICE and LINK statements” on page 37](#) for modifying information.

System environment

In order to configure a single HiperSockets device for both IPv4 and IPv6 traffic, you must use DEVICE/LINK/HOME for the IPv4 definition and INTERFACE for the IPv6 definition, such that the CHPID value on the INTERFACE statement matches the xx portion of the device_name (IUTIQDxx) on the DEVICE statement.

- [“STOP statement” on page 243](#)

DEVICE and LINK - MPCPTP devices statement

When defining a High Performance Data Transfer (HPDT) connection, use the DEVICE statement to specify the name of the TRLE definition for the multipath channel (MPC) group. Also, the TRLE must be defined as MPCLEVEL=HPDT.

When defining an Enterprise Extender connection to the VTAM instance running on this host, use the DEVICE statement to define an IUTSAMEH interface. IUTSAMEH can also be used to define a connection between two TCP/IP stacks on the same system, and the MPCPTP device and link statements can be used to define XCF connections between two TCP/IP stacks in the same sysplex. For more information about configuring Enterprise Extender, see [z/OS Communications Server: SNA Network Implementation Guide](#).

Use the LINK statement to define a network interface link associated with an MPC group when defining an HPDT connection, or a network interface link associated with the IUTSAMEH interface when defining an Enterprise Extender connection.

The preferred way to define XCF and IUTSAMEH connections is to use the IPCONFIG DYNAMICXCF statement.

For more information about missing interrupt handler (MIH) considerations with TCP/IP devices, see [“Missing interrupt handler factors” on page 37](#).

Syntax

Rule: Specify the parameters in the order shown here.

Parameter

device_name

For HPDT MPC connections to an IBM 2216 Multiaccess Connector Model 400, an IBM pSeries, or another z/OS host, the *device_name* must be the TRLE name of an HPDT connection. The TRLE is defined in a VTAM TRL major node and must be active to start the device. For details about defining a TRLE, see [z/OS Communications Server: SNA Resource Definition Reference](#).

The maximum length is eight characters.

The reserved TRLE name IUTSAMEH can be used to bring up an MPCPTP connection between two TCP/IP stacks on the same system without the need for a physical device connection between the two stacks. The reserved TRLE name IUTSAMEH can also be used to define an Enterprise Extender connection to the VTAM instance running on this host. If you are defining an Enterprise Extender connection, the device name must be IUTSAMEH. VTAM automatically activates the IUTSAMEH TRLE.

For XCF connections, the *device_name* must be the CPname or SSCPname of the target VTAM on the other side of the XCF connection, and the VTAM ISTLSXCF major node must be active in both nodes to start the device. The ISTLSXCF major node is created by VTAM dynamically.

Tip: This value is also specified for *device_name* in the MPCPTP LINK statement.

MPCPTP

Specifies the device is a multipath channel point-to-point device.

AUTORESTART | NOAUTORESTART

Controls device failure reactivation behavior.

NOAUTORESTART

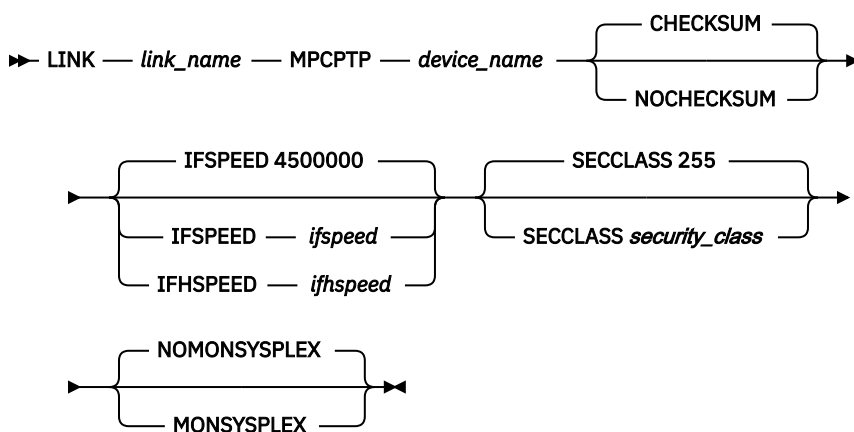

For most device failures, specifying NOAUTORESTART indicates that the TCP/IP address space does not attempt to reactivate this device.

AUTORESTART

In the event of a device failure, the TCP/IP address space attempts to reactivate the device. For more information, see [“Recovering from device failures”](#) on page 36.

Syntax

Rule: The optional parameters on the LINK statement following *device_name* can be specified in any order.

Parameter

link_name

The name of the link. The maximum length is 16 characters. The link name is associated with a home address on the HOME statement.

MPCPTP

Specifies that the link is for MPCPTP.

device_name

The *device_name* must be the same as specified in the DEVICE statement. The maximum length is eight characters.

CHECKSUM

Inbound checksum calculation is performed for all packets received on this interface. This is the default value.

NOCHECKSUM

Inbound checksum calculation is not performed for any packets received on this interface.

The CHECKSUM or NOCHECKSUM setting affects only the inbound TCP/IP data path. This setting has no effect upon the outbound path (checksum calculation is always performed outbound).

While a performance gain can be achieved by specifying NOCHECKSUM, only specify NOCHECKSUM for single-hop MPCPTP links (that is, where application traffic terminates in the adjacent node), such as z/OS to pSeries point-to-point connections. In such a configuration, the z/OS channel provides a reliable data path, thereby minimizing the need for TCP/IP checksum in detecting transmission errors.

Guideline: The TCP/IP checksum is useful in detecting software errors at the sending side, so it is further suggested that NOCHECKSUM be specified only when the sending-side software is considered reliable.

Restriction: Do not specify NOCHECKSUM when the sending side is forwarding packets received over other devices. Systems forwarding packets do not check the transport layer (TCP or UDP) checksums; this is the responsibility of the final destination stack. In this case, disabling checksum processing can result in corrupted data being provided to the application.

IFSPEED *ifspeed*

An optional estimate of the interface's current bandwidth in bits per second. The minimum value for *ifspeed* is 0; the maximum value is 2 147 483 647. The default is 4 500 000. This value is accessible to SNMP for management queries, but has no effect on operation of the device.

IFHSPEED *ifhspeed*

An optional estimate of the interface's current bandwidth in one million bits per second units. The minimum value that can be specified for *ifhspeed* is 0; the maximum value is 2147. The default is 4. This value is accessible to SNMP for management queries, but has no effect on operation of the device.

SECCLASS *security_class*

Use this parameter to associate a security class for IP filtering with this interface. In order for traffic over the interface to match a filter rule, the filter rule must have the same security class value as the interface or a value of 0. Filter rules can be specified in the TCP/IP profile or in an IP Security policy file read by the Policy Agent. Filter rules can include a security class specification on the IpService statement in an IP Security policy file or on the SECCLASS parameter on the IPSEC statement in the TCP/IP profile.

Valid security classes are identified as a number in the range 1 - 255. The default value is 255.

For more information about [security class values](#), see *z/OS Communications Server: IP Configuration Guide*.

Restriction: The TCP/IP stack ignores this value if IPSECURITY is not specified on the IPCONFIG statement.

MONSYSPLEX | NOMONSYSPLEX

Specifies whether or not sysplex autonomics should monitor the link's status.

NOMONSYSPLEX

Specifies that sysplex autonomics should not monitor the link's status. This is the default value.

MONSYSPLEX

Specifies that sysplex autonomics should monitor the link's status.

Restriction: The MONSYSPLEX attribute is not in effect unless the MONINTERFACE keyword is specified on the GLOBALCONFIG SYSPLEXMONITOR profile statement. The presence of

dynamic routes over this link is monitored if the DYNROUTE keyword is also specified on the GLOBALCONFIG SYSPLEXMONITOR profile statement.

Steps for modifying

See [“Modifying DEVICE and LINK statements” on page 37](#) for modifying information.

Usage notes

Requirements:

- In order to configure a single physical device for both IPv4 and IPv6 traffic, you must use DEVICE/LINK/HOME for the IPv4 definition and INTERFACE for the IPv6 definition, such that the TRLENAM value on the INTERFACE statement matches the device_name on the DEVICE statement.
- IUTSAMEH definition is required if you plan to use the Enterprise Extender function and the TCP/IP stack you are configuring is used for access to the IP network by VTAM on this host.

Restriction: A mix of static and dynamic IPv4 and IPv6 definitions for a device is not allowed. For example, if a static IUTSAMEH IPv4 device and link is defined, an IPv6 dynamic definition for IUTSAMEH is created. If a static IUTSAMEH IPv6 interface is defined, an IPv4 dynamic definition for IUTSAMEH is not created. The same logic also applies for XCF links; a mix of static and dynamic IPv4 and IPv6 definitions is not allowed for an XCF link.

- If you start an MPCPTP device and the device does not become active and TCP/IP issues no messages in response to the start request, ensure that the remote end of this HPDT MPC connection is active. Even though the TRLE is active and a start device request was initiated, VTAM holds the TCP/IP start request waiting for the remote side of the HPDT MPC connection to become active.
- For installations that plan on dedicating the MPC group for exclusive use by a single TCP/IP stack, improved performance can be achieved by explicitly defining the MPC group as MPCUSAGE=EXC. For additional information about the MPCUSAGE keyword, see the [z/OS Communications Server: SNA Resource Definition Reference](#).

- [“START statement” on page 242](#)
- [“STOP statement” on page 243](#)

DEVICE and LINK - VIRTUAL devices statement

Use the DEVICE statement to specify the device name of a static virtual device, and use the LINK statement to define the link on the DEVICE statement.

More than one virtual DEVICE/LINK statement can be defined to allow for multiple virtual IP addresses on one TCP/IP image in one MVS system.

Tip: You can also use the INTERFACE statement to define an IPv4 interface for a static VIPA, which combines the definitions of the DEVICE, LINK, and HOME statements into a single statement.

This statement applies to IPv4. See [“INTERFACE - VIRTUAL6 interfaces statement” on page 141](#) for this function in IPv6.

Syntax

Rule: Specify the parameters in the order shown here.

➤ DEVICE — *device_name* — VIRTUAL — *device_number* ➤

Parameter

device_name

The name of the device. The maximum length is 16 characters. The same name is specified in the LINK statement.

VIRTUAL

Specifies that the device is not associated with real hardware and is used for fault tolerance support. The static virtual devices always stay active and are never subject to physical failure.

device_number

The *device_number* must be a hexadecimal number, but the value is ignored. This parameter is included for consistency with the DEVICE statements for other device types.

Syntax

➤ LINK — *link_name* — VIRTUAL — *adapter_address* — *device_name* ➤

Restriction: Only one LINK statement can be defined for each virtual device.

Parameter

link_name

The name of the link. The maximum length is 16 characters. The same name is specified in the HOME statement.

VIRTUAL

Specifies that the link is a virtual link that is not associated with real hardware and is used for fault tolerance support.

adapter_address

The *adapter_address* must be an integer, but the value is ignored. This parameter is included for consistency with the LINK statements for other device types.

device_name

The *device_name* must be the same as specified in the DEVICE statement.

Steps for modifying

See [“Modifying DEVICE and LINK statements” on page 37](#) for modifying information.

Guideline: The steps in the Modifying DEVICE and LINK statements topic that refer to stopping and starting the device do not apply to virtual devices.

Examples

```
DEVICE VDEV1  VIRTUAL 0
LINK  VLINK1  VIRTUAL 0 VDEV1
DEVICE VDEV2  VIRTUAL 1
LINK  VLINK2  VIRTUAL 0 VDEV2
```

Usage notes

- The *device_name* or *link_name* values should not start with VIP because VIP is a restricted keyword.
- A virtual LINK cannot be coded on the START, BEGINROUTES or TRANSLATE statements, but can be coded on a BSDROUTINGPARMS statement for interface characteristics such as subnet mask.

Requirement: If you are running with 3172s configured for multihost connectivity (release 3.5 and later) and want to use VIPA addresses on the host, you must configure the 3172 in one of the following ways:

- As a default router (routes all IP addresses)
- Configure all VIPA addresses in the 3172
- For rules on defining virtual IP addresses for virtual links, see [“HOME statement” on page 76](#).

Related topics

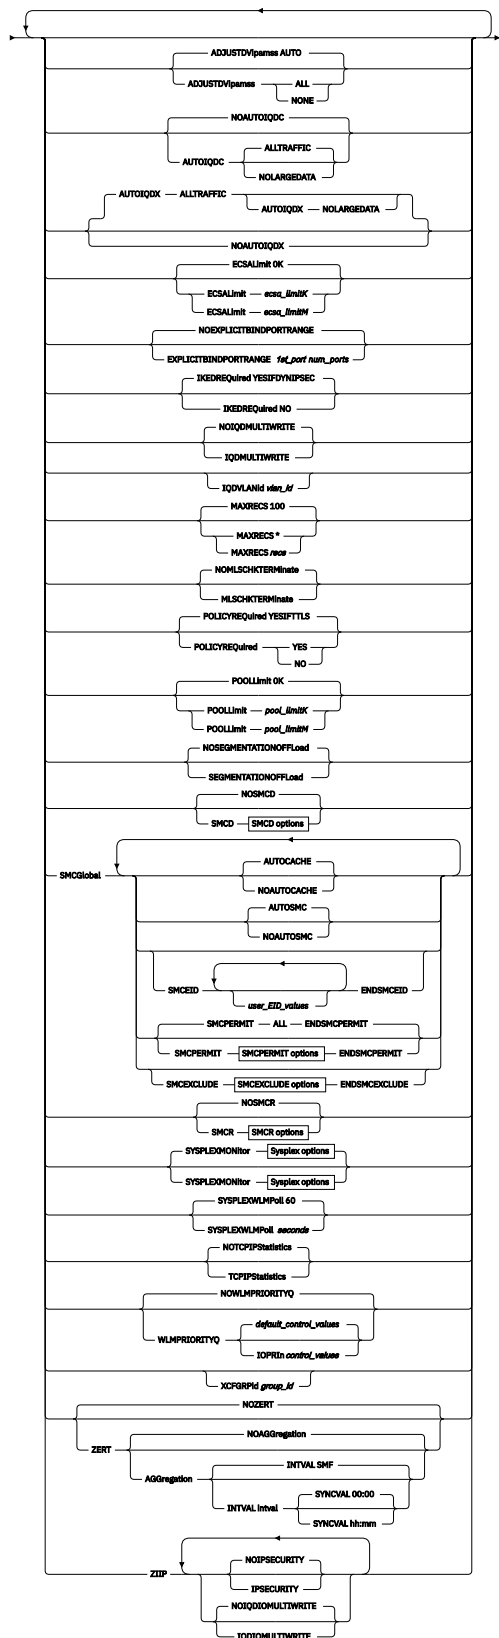

- [“BSDROUTINGPARMS statement” on page 27](#)
- [“HOME statement” on page 76](#)
- [“INTERFACE - VIRTUAL interfaces statement” on page 109](#)
- [“IPCONFIG statement” on page 143](#)
- [“VIPADYNAMIC statement summary” on page 253](#)

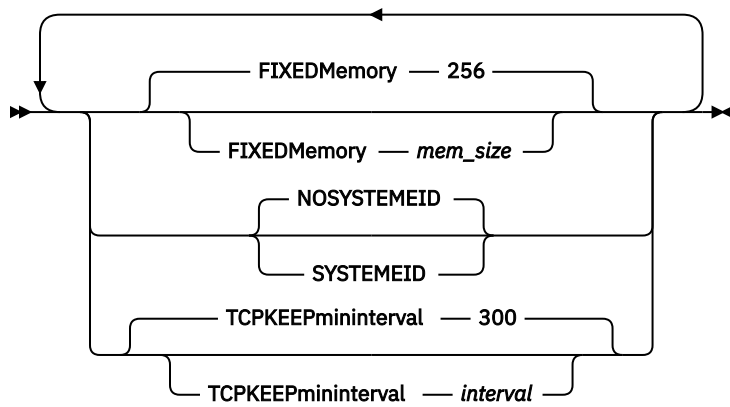

GLOBALCONFIG statement

Use the GLOBALCONFIG statement to pass global configuration parameters to TCP/IP.

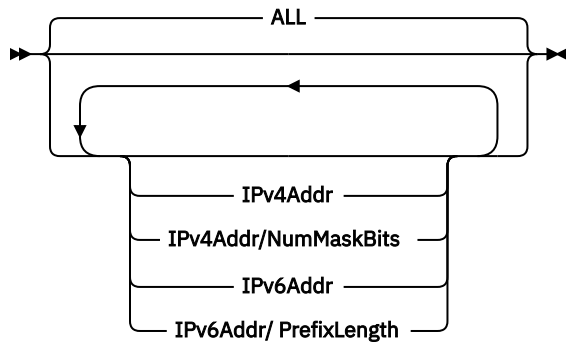

Syntax

Tip: Specify the parameters for this statement in any order.

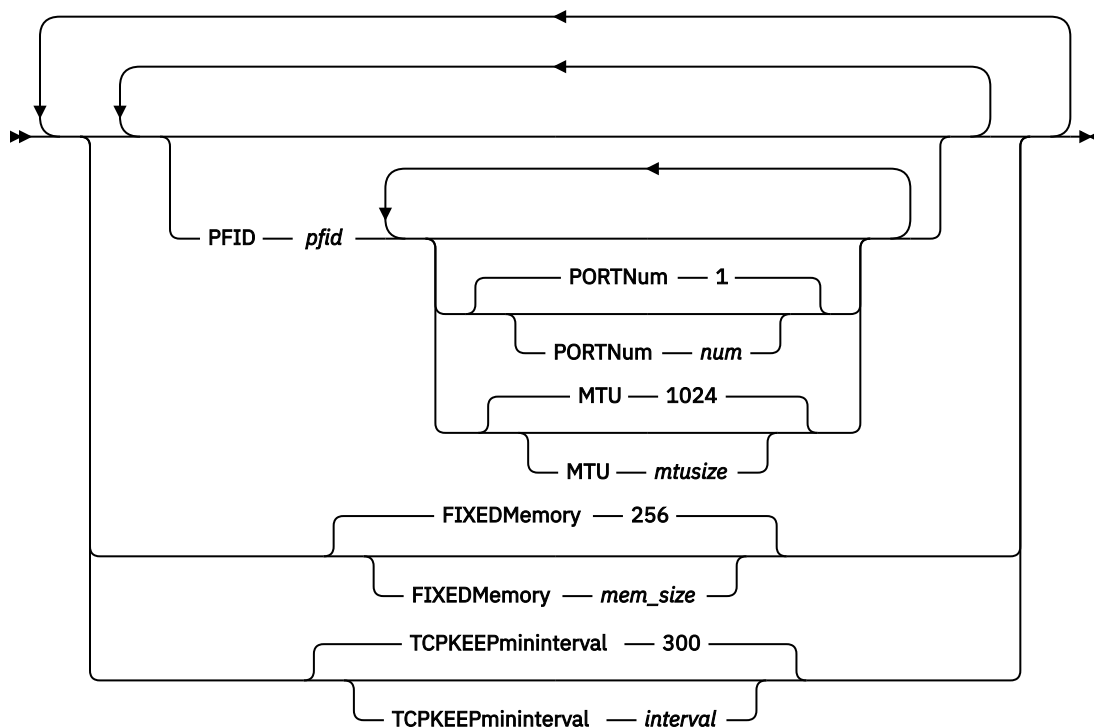

SMCPERMIT options

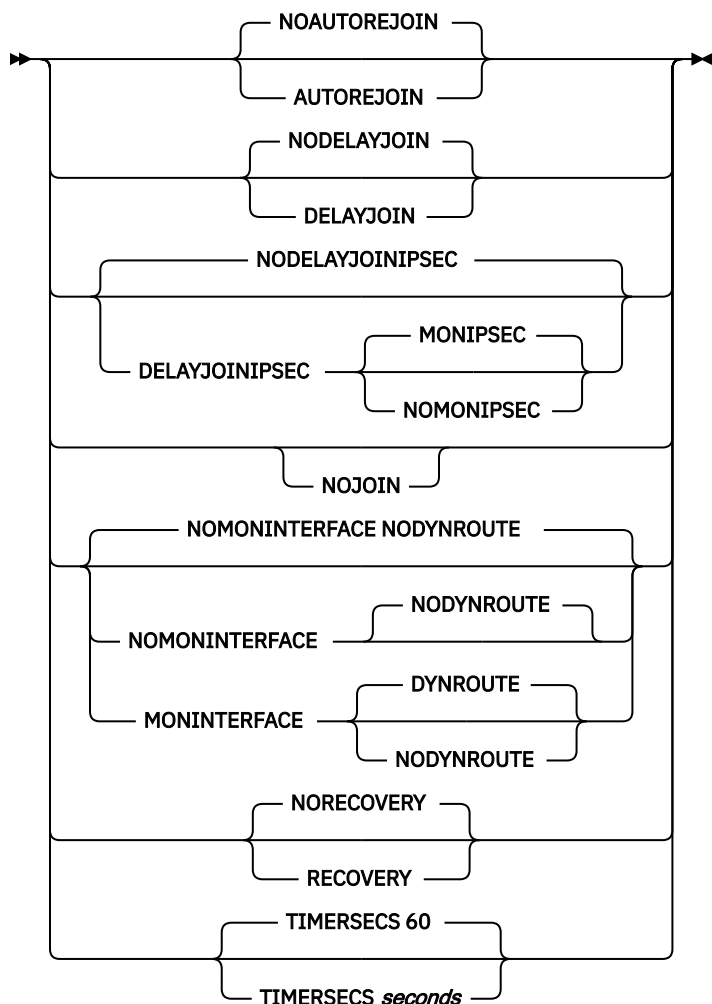

SMCEXCLUDE options

SMCR options

Sysplex options

Parameters

ADJUSTDVIPAMSS AUTO | ALL | NONE

Specifies sub parameters to control whether TCP/IP changes the Maximum Segment Size (MSS) that is advertised for a TCP connection. Connections that use VIPAROUTE to forward Sysplex Distributor packets add a Generic Routing Encapsulation (GRE) header to the packet. The addition of a GRE header increases the packet size and can cause IP fragmentation between the distributor and the target stack. To avoid this fragmentation, the length of the GRE header can be subtracted from the MSS that TCP connections advertise at connection establishment. Changes to ADJUSTDVIPAMSS affect only the new connections.

AUTO

Indicates that TCP/IP automatically adjusts the MSS to accommodate the length of a GRE header. For inbound connections on a target stack, the MSS is adjusted if the destination address is a distributed DVIPA and VIPAROUTE is being used. For outbound connections on a target stack, the MSS is adjusted if the source IP address is a distributed DVIPA. This is the default value.

ALL

Indicates that TCP/IP adjusts the MSS for connections that use a DVIPA as the local IP address, whether the DVIPA is distributed or not.

NONE

Indicates that TCP/IP does not adjust the MSS for any connections.

AUTOIQDC | NOAUTOIQDC

Specifies whether to dynamically create Internal Queued Direct I/O (IQD) interfaces and transparently converge the dynamic IQD interfaces with the associated OSA interfaces. The IQD interface that is dynamically created and managed is logically converged with the OSA interface and is referred to as a HiperSockets Converged Interface (IQDC).

See “Steps for modifying” on page 71 for details about changing this parameter while the TCP/IP stack is active. See [z/OS Communications Server: IP Configuration Guide](#) for information about the HiperSockets Converged Interface and the IQD External Bridge function.

NOAUTOIQDC

Do not use dynamic IQD (HiperSockets) converged interfaces. This value is the default value.

AUTOIQDC

Dynamically manage access to IQD (HiperSockets). AUTOIQDC will dynamically create / delete, start / stop, and transparently converge IQD interfaces (IQDC) with your OSA interfaces for external networks. AUTOIQDC applies to OSA interface statements. The OSA interface statement must also have been defined with the virtual MAC (VMAC) parameter to request an OSA-generated VMAC address.

The OSA CHPID associated with your OSA interface must have a PNetID configured in HCD for the associated OSA port. The dynamic IQD interface is created if an IQD CHPID is found to be configured (in HCD) with the External Bridge function and a PNetID that matches your OSA PNetID.

ALLTRAFFIC

Use IQD interfaces for all eligible outbound traffic flowing on the external IP data network. This value is the default value.

NOLARGEDATA

Do not use IQD dynamic interfaces for outbound TCP socket data transmissions of length 32 KB or larger. Use dynamic IQD interfaces for all other eligible outbound traffic. See [z/OS Communications Server: IP Configuration Guide](#) for more information about this setting.

Tips:

- When coding AUTOIQDC, also code IQDIOMULTIWRITE on the GLOBALCONFIG statement to optimize outbound write processing over all HiperSockets interfaces.
- Even when coding AUTOIQDC, some traffic might use the OSA interface to avoid fragmentation. If you use jumbo frames for your OSD interfaces that are associated with a converged

HiperSockets CHPID, specify (in HCD) an IQD frame size larger than 16 KB when you configure your converged HiperSockets CHPID. This avoids fragmentation, which allows more traffic to flow over the converged HiperSockets interface.

AUTOIQDX | NOAUTOIQDX

Specifies whether to use dynamic Internal Queued Direct I/O extensions (IQDX) interfaces for connectivity to the intraensemble data network.

See “Steps for modifying” on page 71 for details about changing this parameter while the TCP/IP stack is active. See [z/OS Communications Server: IP Configuration Guide](#) for information about the TCP/IP in an ensemble.

NOAUTOIQDX

Do not use dynamic IQDX interfaces.

AUTOIQDX

Use dynamic IQDX interfaces when an IQD CHPID has been configured with the Internal Queued Direct I/O extensions (IQDX) function. This value is the default value.

ALLTRAFFIC

Use IQDX interfaces for all eligible outbound traffic on the intraensemble data network. This value is the default value.

NOLARGEDATA

Do not use IQDX interfaces for outbound TCP socket data transmissions of length 32KB or larger. Use IQDX interfaces for all other eligible outbound traffic. See [z/OS Communications Server: IP Configuration Guide](#) for more information.

ECSALIMIT *ecsalimit* K | M

Specifies the maximum amount of extended common service area (ECSA) that TCP/IP can use. This limit can be expressed as a number followed by a K (which represents 1024 bytes), or a number followed by an M (which represents 1048576 bytes). If the K suffix is used, *ecsalimit* must be in the range 10240K and 2096128K inclusive or 0. If the M suffix is used, *ecsalimit* must be in the range 10M and 2047M inclusive or 0. The default is no limit, and it can be specified as 0 K or 0 M. The minimum value for ECSALIMIT and POOLLIMIT is not allowed to be set to a value if the current storage in use would be greater than or equal to 80% of that value (for example, not allowed to set it such that there is an immediate storage shortage).

ECSALIMIT ensures that TCP/IP does not overuse common storage. It is intended to improve system reliability by limiting TCP/IP's storage usage. The limit must account for peak storage usage during periods of high system activity or TCP/IP storage abends might occur. The limit does not include storage used by communications storage manager (CSM). CSM ECSA storage is managed independently of the TCP/IP ECSALIMIT. See [z/OS Communications Server: SNA Network Implementation Guide](#) for more information about CSM.

Specifying a nonzero ECSALIMIT enables warning messages EZZ4360I, EZZ4361I, and EZZ4362I to appear if a storage shortage occurs.

EXPLICITBINDPORTRANGE | NOEXPLICITBINDPORTRANGE

NOEXPLICITBINDPORTRANGE

Indicates that this stack does not participate in the allocation of ports from a pool of ports. The ports in the pool are guaranteed to be unique across the sysplex in that they are allocated to only one requestor in the sysplex at any one time, when processing an explicit bind() of a TCP socket to the IPv4 INADDR_ANY address, or to the IPv6 unspecified address (in6addr_any), and port 0.

EXPLICITBINDPORTRANGE

Indicates that this stack participates in the allocation of ports from a pool of ports guaranteed to be unique across the sysplex, when processing an explicit bind() of a TCP socket to the IPv4 INADDR_ANY address, or to the IPv6 unspecified address (in6addr_any), and port 0. This parameter also designates the range of ports that defines that pool. This parameter defines the range used by all stacks participating in EXPLICITBINDPORTRANGE port allocation processing throughout the sysplex. The most recently processed profile or OBEYFILE command that specifies EXPLICITBINDPORTRANGE defines the range for the sysplex.

Use this parameter so that you can specify distributed DVIPAs as the source IP address on DESTINATION or JOBNAME rules in a SRCIP block. See [“SRCIP statement”](#) on page 233.

1st_port

The starting port for the range of ports. The *1st_port* value is in the range 1024 - 65535. The sum of the *1st_port* value plus the *num_ports* value minus 1 cannot exceed 65535.

num_ports

The number of ports in the range. The *num_ports* value is in the range 1 - 64512. The sum of the *1st_port* value plus the *num_ports* value minus 1 cannot exceed 65535.

Guidelines:

- All TCP/IP stacks in the sysplex that participate in EXPLICITBINDPORTRANGE processing should have the same port range specified. To ensure this, specify the GLOBALCONFIG EXPLICITBINDPORTRANGE statement in a file that is specified in an INCLUDE statement in the TCP profiles data set of all the participating stacks.
- The port range defined on the EXPLICITBINDPORTRANGE parameter should not overlap any existing port reservations of any TCP/IP stacks in the sysplex. Any reserved ports that are within the EXPLICITBINDPORTRANGE range are excluded from the EXPLICITBINDPORTRANGE port pool, effectively making the pool smaller.
- The EXPLICITBINDPORTRANGE port range must be large enough to accommodate all applications in the sysplex that might issue explicit bind() calls for the IPv4 INADDR_ANY address, or for the IPv6 unspecified address (in6addr_any), and port 0.
- If additional TCP/IP stacks or systems are introduced into the sysplex, the extent of the port range defined by EXPLICITBINDPORTRANGE should be re-evaluated.
- If the size of the port range defined by the EXPLICITBINDPORTRANGE parameter is too large, there are fewer ports available for local ephemeral port allocation.

Restriction: In a common INET (CINET) environment, this parameter is accepted, but the EXPLICITBINDPORTRANGE function is supported in a limited set of conditions only. It is supported when CINET is managing one stack only on the system or when the affected application has established stack affinity. Otherwise, results can be unpredictable.

IQDMULTIWRITE | NOIQDMULTIWRITE

Specifies whether HiperSockets interfaces should use multiple write support. HiperSockets multiple write might reduce CPU usage and might provide a performance improvement for large outbound messages that are typically generated by traditional streaming workloads such as file transfer, and interactive web-based services workloads such as XML or SOAP. This parameter applies to all HiperSockets interfaces, including IUTIQDIO and IQDIOINTF6 interfaces created for Dynamic XCF.

Restriction: HiperSockets multiple write is effective only on an IBM z10 or later and when z/OS is not running as a guest in a z/VM® environment.

See the modifying information in this topic for details about changing this parameter while the TCP/IP stack is active. See the [HiperSockets multiple write information in z/OS Communications Server: IP Configuration Guide](#) for more information about HiperSockets multiple write support.

NOIQDMULTIWRITE

HiperSockets interfaces do not use the multiple write support. This is the default.

IQDMULTIWRITE

HiperSockets interfaces do use the multiple write support.

IQDVLANID *vlan_id*

Specifies a VLAN ID to be used when HiperSockets (iQDIO) connectivity is used for dynamic XCF support. VLAN IDs are used to partition communication across HiperSockets. Stacks on the same CPC using the same HiperSockets CHPID that use the same VLAN ID can establish communications; stacks on the same CPC using the same HiperSockets CHPID that use different VLAN IDs cannot.

The specified value, *vlan_id*, is used for both IPv4 and IPv6 DYNAMICXCF HiperSockets connectivity. This parameter is intended to be used in conjunction with the GLOBALCONFIG XCFGRPID parameter to support subplexing.

Subplexing enables TCP/IP participation in a Sysplex to be partitioned into subsets based on the XCFGRPID value. When using subplexing, TCP/IP stacks with the same XCFGRPID value should specify the same IQDVLANID value. Stacks with different XCFGRPID values should have different IQDVLANID values. If you have stacks in the default subplex (that is, stacks that do not specify an XCFGRPID value) that use the same HiperSockets CHPID as stacks within a non-default subplex (an XCFGRPID value was specified), then the stacks in the default subplex should specify an IQDVLANID value that is different from the other IQDVLANID values specified by the other non-default subplex stacks that use the same HiperSockets CHPID.

Restriction: The IQDVLANID parameter can be specified only in the initial profile.

Valid VLAN IDs are in the range 1 - 4094. For more information about VLANs and Hipersockets see [z/OS Communications Server: IP Configuration Guide](#).

MAXRECS

Specifies the maximum number of records to be displayed by the DISPLAY TCPIP,,NETSTAT operator command. The term *records* refers to the number of entries displayed on each report. For example, for the connection-related reports, a record is a TCP connection or listener, or a UDP endpoint. This configured value is used when the MAX parameter is not explicitly specified on the command. The default value is 100. If the number of output lines exceeds the maximum number of lines for a multi-line Write to Operator (WTO), the report output is truncated. See the information about the [Display TCPIP,,NETSTAT](#) command in [z/OS Communications Server: IP System Administrator's Commands](#) for more details about the command.

A value of asterisk (*) specifies that all records are to be displayed.

recs

This value specifies the number of records to be displayed. The valid range is 1 - 65535.

MLSCHKTERMINATE | NOMLSCHKTERMINATE

NOMLSCHKTERMINATE

Specifies that the stack should remain active after writing an informational message when inconsistent configuration information is discovered in a multilevel-secure environment.

Informational message EZD1217I is written to the system console summarizing the number of problems found. Additional informational messages between EZD1219I and EZD1234I are written to the job log for each configuration inconsistency found.

This is the default value.

MLSCHKTERMINATE

Specifies that the stack should be terminated after writing an informational message when inconsistent configuration information is discovered in a multilevel-secure environment.

Informational message EZD1217I is written to the system console summarizing the number of problems found. Additional informational messages between EZD1219I and EZD1234I are written to the job log for each configuration inconsistency found.

POLICYREQUIRED YESIFTTLS | YES | NO

Specifies sub parameters to control the timing of the output of message EZD1314I TCP/IP AND EXTENDED SERVICES ARE NOW INITIALIZED. The message will be generated at a different time depending on the option that is specified.

YESIFTTLS

If AT-TLS is configured in the TCP/IP profile (TCPCONFIG TTLS), the stack will wait for Policy Agent processing to complete before issuing EZD1314I. If AT-TLS is not configured in the profile, the stack will issue EZD1314I without waiting for Policy Agent. This is the default option.

YES

The stack will wait for Policy Agent processing to complete before issuing EZD1314I.

Tip: This option should be considered if you know subsystems/processes are reliant on policies other than, or in addition to, AT-TLS (IPSec, QoS, IDS, etc.)

NO

The stack will issue EZD1314I without waiting for the Policy Agent to process policies.

Tip: This option should be considered if you do not require any policies to be installed to the stack before continuing operations.

IKEDREQUIRED YESIFDYNIPSEC | NO

Specifies sub parameters to control the timing of the output of message EZD1314I TCP/IP AND EXTENDED SERVICES ARE NOW INITIALIZED. Depending on the option specified, IKED initialization may or may not be required before EZD1314I is output.

YESIFDYNIPSEC

If all of the following conditions are met, the stack will wait for IKED initialization before issuing EZD1314I:

- IPSECURITY is configured on the IPCONFIG statement of the TCP/IP profile.
- POLICYREQUIRED YESIFTTLS (TCPCONFIG TTLS) or POLICYREQUIRED YES is configured on the GLOBALCONFIG statement of the TCP/IP profile.
- IPSec policy includes dynamic filter rules.

Otherwise the stack will not wait for IKED initialization before issuing EZD1314I.

This is the default option.

NO

The stack will not wait for IKED initialization before issuing EZD1314I.

Tip: This option should be considered if you do not require IKED to be active before continuing operations. An example of this would be when the only IPSec protection required for this stack is for target-only DVIPAs.

POOLLIMIT *pool_limit* K | M

Specifies the maximum amount of authorized private storage that TCP/IP can use within the TCP/IP address space. This limit can be expressed as a number followed by a K (which represents 1024 bytes), or a number followed by an M (which represents 1048576 bytes). If the K suffix is used, *pool_limit* must be in the range 10240K and 2096128K inclusive or 0. If the M suffix is used, *pool_limit* must be in the range 10M and 2047M inclusive or 0. The default is no limit, and it can be specified as 0K or 0M. The minimum value for ECSALIMIT and POOLLIMIT is not allowed to be set to a value if the current storage in use would be greater than or equal to 80% of that value (for example, not allowed to set it such that there is an immediate storage shortage).

POOLLIMIT ensures that TCP/IP does not overuse its authorized private storage. Most systems can use the default POOLLIMIT (no limit). Systems with limited paging capacity can use POOLLIMIT to help limit TCP/IP storage usage. If the limit is used, it must account for peak storage usage during periods of high system activity or TCP/IP storage abends might occur.

POOLLIMIT can be higher than the REGION size on the TCP/IP start procedure because POOLLIMIT applies to authorized storage, whereas REGION applies to unauthorized storage. Specifying a nonzero POOLLIMIT enables warning messages EZZ4364I, EZZ4365I, and EZZ4366I to appear if a storage shortage occurs.

SEGMENTATIONOFFLOAD | NOSEGMENTATIONOFFLOAD

Specifies whether the stack should offload TCP segmentation for IPv4 packets to OSA features. TCP segmentation offload support transfers the overhead of segmenting outbound data into individual TCP packets to OSA devices whose features support this function. Offloading segmentation of streaming-type workloads reduces CPU use and increases throughput.

Guideline: The support for specifying IPv4 segmentation offload on the GLOBALCONFIG profile statement has been deprecated. The parameters are still supported on the GLOBALCONFIG statement, but the support for specifying these parameters on the GLOBALCONFIG statement will be dropped in a future release. It is recommended to specify these parameters on the IPCONFIG profile statement instead.

Rule: The SEGMENTATIONOFFLOAD and NOSEGMENTATIONOFFLOAD parameters specified on the IPCONFIG statement override the equivalent parameters specified on the GLOBALCONFIG statement.

See the Modifying topic for information about changing this parameter while the TCP/IP stack is active. See [segmentation offload information in z/OS Communications Server: IP Configuration Guide](#) for more information about TCP segmentation offload support.

NOSEGMENTATIONOFFLOAD

TCP segmentation is performed by the TCP/IP stack. This is the default.

SEGMENTATIONOFFLOAD

TCP segmentation is offloaded to the OSA feature.

SMCD | NOSMCD

Specifies whether this stack uses Shared Memory Communications - Direct Memory Access (SMC-D). For more information about SMC-D, see [Shared Memory Communications - Direct Memory Access in z/OS Communications Server: IP Configuration Guide](#).

NOSMCD

Specifies that this stack should not use SMC-D communications. This is the default setting.

SMCD

Specifies that this stack should use SMC-D communications. You can use this parameter to define operational characteristics for SMC-D communications.

Result: The AUTOCACHE and AUTOSMC monitoring functions are started if SMCGLOBAL AUTOCACHE and AUTOSMC are configured, either by default or by being explicitly specified.

If you specify the SMCD parameter without any sub parameters, you get one of the following results:

- If you specify the SMCD parameter for the first time, the FIXEDMEMORY and TCPKEEPMININTERVAL sub parameters are set to default values.
- If you previously specified the SMCD parameter with sub parameters, TCP/IP retains the knowledge of the sub parameter settings, even if SMC-D processing is stopped by issuing the VARY TCPIP,,OBEYFILE command with a data set that contains a GLOBALCONFIG NOSMCD parameter. Therefore, a subsequent specification of a GLOBALCONFIG SMCD profile statement resumes SMC-D processing with the previous sub parameter settings.

FIXEDMEMORY *mem_size*

Specifies the maximum amount of 64-bit storage that the stack can use for the receive buffers that are required for SMC-D communications. The *mem_size* value is an integer in the range 30 - 9999, and represents the maximum storage in megabytes of data. The default value is 256 megabytes.

SYSTEMEID | NOSYSTEMEID

Specifies whether or not a system EID will be generated for use with SMC-Dv2. The system EID (SEID) is an internal EID that is built by the SMC-Dv2 software stack that has a predefined, constant value representing the CPC that the OS is executing on. The IBM Z SEID is a globally unique ID representing an IBM CPC (type and serial are encoded within the SEID). The SEID format is consistent with the UEID (32-character bytes) format. The SEID is only applicable to SMC-Dv2.

NOSYSTEMEID

The SEID will not be generated and SMC-Dv2 will only be enabled if SMCEID is configured. This is the default.

SYSTEMEID

The SEID will be generated for use with SMC-Dv2. In cases where SMCEID is not configured, this option also activates SMC-Dv2 functionality.

TCPKEEPMININTERVAL *interval*

This interval specifies the minimum interval that TCP keepalive packets are sent on the TCP path of an SMC-D link.

Rules:

- If a keepalive interval is also specified on the INTERVAL parameter of the TCPCONFIG statement or is set for a specific SMC-D link socket by the TCP_KEEPAIVE setsockopt() option, the largest of the three interval values is used.
- The valid range for this interval is 0-2147460 seconds, and the default value is 300 seconds.
- A value of 0 disables TCP keepalive probe packets on the TCP path of an SMC-D link.
- The SO_KEEPAIVE setsockopt() option must be set to use keepalive processing.

Result: The TCPKEEPMININTERVAL setting has no effect on keepalive processing for the SMC-D path of an SMC-D link.

For more information about TCP keepalive processing for the TCP path and the SMC-D path of SMC-D links, see [TCP keepalive in z/OS Communications Server: IP Configuration Guide](#).

SMCGLOBAL

Specifies global settings for Shared Memory Communications (SMC). SMC includes Shared Memory Communications over Remote Direct Memory Access (RDMA), or SMC-R, for external data network communications and Shared Memory Communications - Direct Memory Access (SMC-D). For more information about SMC-R and SMC-D, see [Shared Memory Communications in z/OS Communications Server: IP Configuration Guide](#).

AUTOCACHE | NOAUTOCACHE

Specifies whether this stack caches unsuccessful attempts to use SMC communication. Use SMCGLOBAL AUTOCACHE to prevent the overhead of persistent attempts to establish a TCP connection to a specific destination IP address over SMC if previous attempts to the same destination failed.

NOAUTOCACHE

Specifies that this stack does not cache unsuccessful attempts to create an SMC-R or SMC-D link and that existing SMC cache entries are cleared.

AUTOCACHE

Specifies that this stack caches unsuccessful attempts to create an SMC-R or SMC-D link per destination IP address. Subsequent TCP connections to the same destination bypass the use of SMC while the IP address is cached. To clear this cache, specify the NOAUTOCACHE sub parameter. Cached entries remain in effect for approximately 20 minutes. AUTOCACHE is the default setting. The AUTOCACHE function is started only when you enable SMC. For more information about enabling SMC, see the description of the GLOBALCONFIG SMCR and SMCD parameters.

AUTOSMC | NOAUTOSMC

Specifies whether this stack monitors inbound TCP connections to dynamically determine whether SMC is beneficial for a local TCP server application. Results of this monitoring influence whether TCP connections to a particular server or port use SMC. AUTOSMC monitoring ensures that TCP connections use the most appropriate communications protocol, either TCP or SMC. You can use the Netstat ALL/-A command to monitor the results of this dynamic monitoring and SMC enablement or disablement. For more information about the Netstat ALL/-A command, see [Netstat ALL/-A in z/OS Communications Server: IP System Administrator's Commands](#).

Guideline: Configuration of either SMC or NOSMC on the PORT or PORTRANGE statement overrides configuration of the AUTOSMC monitoring function for particular servers. For more information, see [“PORT statement” on page 207](#) and [“PORTRANGE statement” on page 216](#).

NOAUTOSMC

Specifies that this stack does not monitor inbound TCP connections to determine whether the connections can benefit from using SMC.

AUTOSMC

Specifies that this stack monitors inbound TCP connections to determine whether the connections can benefit from using SMC. AUTOSMC is the default setting. The AUTOSMC monitoring function is started only when you enable SMC. For more information about enabling SMC, see the description of the GLOBALCONFIG SMCR and SMCD parameters.

SMCPERMIT/ENDSMCPERMIT

Specifies the SMC filter that allows SMC negotiation with peers within the listed TCP/IP address(es)/subnet(s). If the user implements the SMCPERMIT, only the defined IP address/subnets will be allowed to participate in SMC by including the TCP/IP SMCR option in the TCP 3-way handshake. This filter applies to both the z/OS client and server and is applied to the peer host's TCP/IP connection IP address/subnet. When Permit filters are defined, one of the filters must match the peer's IP address/subnet to allow SMC negotiation to proceed.

SMCPERMIT

Allows the users to specify up to 256 IP addresses/subnets/prefixes each for IPv4 and IPv6 categories. If SMCPERMIT/ENDSMCPERMIT is configured as an empty block with no IP addresses specified or specified with the keyword ALL, then SMC negotiation will be allowed to proceed for all IP addresses/subnets.

Specifying SMC filters is optional. When not specified, the default will be the same as if "SMCPERMIT ALL ENDSMCPERMIT" is specified.

IPv4Addr

The destination IPv4 address. This can be a TCP/IP address or subnet. Users can specify up to 256 IP addresses.

NumMaskBits

An integer value in the range 1 - 32 that represents the number of leftmost significant bits for the address mask of an IPv4 address. If not specified, it will be defaulted to 32.

IPv6Addr

The destination IPv6 address. For IPv6, the destination address can be a host, prefix or default address. In addition, multiple routes having an identical destination IP address and address mask can be specified.

PrefixLength

An integer value in the range 1 - 128 representing the number of bits in the ipaddr value that are used to determine the destination address of the IPv6 address. If not specified, it will be defaulted to 128.

SMCEXCLUDE/ENDSMCEXCLUDE

Specifies the SMC filter that prevents SMC negotiation with peers within the listed TCP/IP address(es)/subnet(s). If the user implements the SMCEXCLUDE, then the defined IP address/subnets will not be allowed to participate in SMC. When the SMCEXCLUDE list is empty or SMCEXCLUDE is not specified, then there will be no entries on the Exclude list (So no IP addresses/subnets/prefixes will be explicitly excluded). This filter applies to both the z/OS client and server. The processing of filters specified in SMCEXCLUDE takes precedence over those specified in SMCPERMIT when there is an overlap in the IP addresses specified.

SMCEXCLUDE

Allows the users to specify up to 256 IP addresses/subnets/prefixes each for IPv4 and IPv6 categories. If SMCEXCLUDE/ENDSMCEXCLUDE is configured as an empty block with no IP addresses specified, SMC negotiation will be allowed to proceed for all IP addresses/subnets.

Specifying SMC filters is optional. When not specified, the default will be the same as if an empty SMCEXCLUDE/ENDSMCEXCLUDE block is specified.

IPv4Addr

The destination IPv4 address. This can be a TCP/IP address or subnet. Users can specify up to 256 IP addresses.

NumMaskBits

An integer value in the range 1 - 32 that represents the number of leftmost significant bits for the address mask of an IPv4 address. If not specified, it will be defaulted to 32.

IPv6Addr

The destination IPv6 addresses. For IPv6, the destination address can be a host, prefix or default address. In addition, multiple routes having an identical destination IP address and address mask can be specified.

PrefixLength

An integer value in the range 1 - 128 representing the number of bits in the ipaddr value that are used to determine the destination address of the IPv6 address. If not specified, it will be defaulted to 128.

SMCEID/ENDSMCEID

The SMCEID/ENDSMCEID block allows the users to specify up to 4 user-defined EIDs (UEIDs). The presence of any UEIDs will enable SMCv2. For example, if SMCEID/ENDSMCEID is configured as an empty block with no UEIDs specified, SMCv2 will not be enabled. Similarly, if SMCv2 is already enabled, and then SMCEID/ENDSMCEID is configured as an empty block with no UEIDs specified, this will disable SMC-Rv2; it will also disable SMC-Dv2 as long as the SYSTEMEID keyword was not configured under the SMCD section of the profile.

Restriction:

SMC-Dv2 supports both IPv4 and IPv6. SMC-Rv2 supports IPv4 only.

SMCEID

Allows for up to 4 EIDs to be configured. If any EIDs are configured, SMCv2 functionality will be enabled. By default, SMCEID is not configured and SMCv2 is disabled.

user_EID_values

A user defined identifier that represents a group of systems that are allowed to communicate using SMC over multiple IP subnets using the SMC V2 protocol. The EID is a user defined, fixed length, 32-byte character (ASCII 4) field defined within the SMCv2 CLC messages supporting any valid combination of valid ASCII characters (ASCII 4) with no spaces or blanks. Below are the rules to follow when configuring a user EID.

Rules:

- The characters are capitalized alphanumeric in addition to allowing both the "." and "-" special characters (A-Z,0-9,-,.).
- A UEID however, may not start with any special character.
- A UEID might not have consecutive "." characters.
- UEIDs should be globally unique. IBM provides guidelines for creating globally unique EIDs.

SMCR | NOSMCR

Specifies whether this stack uses Shared Memory Communications over Remote Direct Memory Access (RDMA), or SMC-R, for external data network communications. For more information about SMC-R, see [Shared Memory Communications over Remote Direct Memory Access in z/OS Communications Server: IP Configuration Guide](#).

NOSMCR

Specifies that this stack should not use SMC-R for external data network communications. This is the default setting.

SMCR

Specifies that this stack should use SMC-R for external data network communications. Use this parameter to define the *RoCE* features that this stack should use for SMC-R communications. You can use this parameter to define additional operational characteristics for SMC-R communications.

Result: If at least one PFID is defined, the AUTOCACHE and AUTOSMC monitoring functions are started if SMCGLOBAL AUTOCACHE and AUTOSMC are configured, either by default or by being explicitly specified.

If you specify the SMCR parameter without any sub parameters, you get one of the following results:

- If this is the first time that you specify the SMCR parameter, the following results occur:
 - No Peripheral Component Interconnect Express (PCIe) function IDs are defined.
 - FIXEDMEMORY and TCPKEEPMININTERVAL sub parameters are set to default values.

- If you previously specified the SMCR parameter with sub parameters, TCP/IP retains the knowledge of the sub parameter settings, even if SMC-R processing is stopped by issuing the VARY TCPIP,,OBEYFILE command with a data set that contains a GLOBALCONFIG NOSMCR parameter. Therefore, a subsequent specification of a GLOBALCONFIG SMCR profile statement resumes SMC-R processing with the previous sub parameter settings.

PFID *pfid*

Specifies the Peripheral Component Interconnect Express (PCIe) function ID (PFID) value for a *RoCE* feature that this stack uses. PFIDs specified here will allow for SMC-Rv1 communications. (For multiple IP subnet support (SMC-Rv2 communications), you must specify the SMC-Rv2 parameters (PFID, SMCRIPADDR) on the OSA INTERFACE statement.) A *pfid* is a 2-byte hexadecimal value that identifies this TCP/IP stack's representation of a *RoCE* supports values for *pfid* in the range 0 to FFFF. The maximum supported PFID value depends on the System z[®] machine level.

The PFID configured on the OSA INTERFACE statement is used for SMC-Rv2 communications. When SMC-Rv1 communications are also required, configuring the same PFID on the GLOBALCONFIG statement enables this PFID for SMC-Rv1. However, the VLAN definition for the INTERFACE statement impacts the SMC-Rv1 communications capability as follows:

- When VLAN is configured on the INTERFACE statement (trunk mode), this PFID can also be used for SMC-Rv1 communications. For this case, configuring this same PFID on the GLOBALCONFIG statement enables SMC-Rv1 connectivity.
- When VLAN is not configured on the INTERFACE statement (access mode), this PFID can conditionally be used for SMC-Rv1 connectivity described as follows:
 - When the OSA interface and all *RoCE* PFIDs on the PNET that are to be used for SMC-Rv1 connectivity are all defined in the associated switch ports with a single VLAN ID, SMC-Rv1 connectivity is supported. For this case, the PFID should be configured on the GLOBALCONFIG statement.

Restriction: When the OSA interface and all *RoCE* PFIDs on the PNET that are to be used for SMC-Rv1 connectivity are not defined in the associated switch ports with a single VLAN ID, SMC-Rv1 connectivity is not supported. When enabling SMC-Rv2 communications in this access mode configuration the PFID must not be configured on the GLOBALCONFIG statement.

Result: Configuring PFID on the GLOBALCONFIG statement for this case could result in connection hangs with SMC-Rv1 link timeouts.

Rules:

- You must code at least one PFID sub parameter for this stack to use SMC-R communications.
- You can specify a maximum of 16 PFID sub parameter values on the SMCR parameter.
- The value for each PFID and PORTNUM pair must be unique.
- When the *RoCE* feature operates in a shared *RoCE* environment, you cannot simultaneously activate a *RoCE* feature that uses the same PFID value from different TCP/IP stacks within the same logical partition (LPAR).

PORTNUM *num*

Specifies the *RoCE* port number to use for a particular PFID. Configure each PFID to use only a single port. The port number can be 1 or 2; 1 is the default value.

Rules:

- You do not need to configure PORTNUM for IBM *RoCE* Express2 or *RoCE* Express3 features in the TCP/IP profile. The correct port number for these features is configured in the Hardware Configuration Definition (HCD) and is learned by VTAM and the TCP/IP stack during PFID activation. VTAM ignores the GLOBALCONFIG SMCR PORTNUM value if it differs from the port number configured in the HCD for the IBM *RoCE* Express2/*RoCE* Express3 feature.

- If the 10 GbE RoCE Express feature operates in a dedicated RoCE environment, you can activate either port 1 or port 2 but not both simultaneously for an individual PFID value. If PORTNUM 1 and PORTNUM 2 definitions for the same PFID value are created, the port that is first activated is used.
- If the 10 GbE RoCE Express feature operates in a shared RoCE environment, you can use both port 1 and port 2 on an individual RNIC adapter, but the PFID value that is associated with each port must be different. You cannot simultaneously activate PORTNUM 1 and PORTNUM 2 definitions for the same PFID value.

For example, if PFID 0013 and PFID 0014 are both defined in HCD to represent the RNIC adapter with PCHID value 0140, you can configure PFID 0013 PORT 1 PFID 0014 PORT 2 to use both ports on the RNIC adapter. However, if you specify PFID 0013 PORT 1 PFID 0013 PORT 2, only the first port that is activated is used.

MTU *mtusize*

Specifies the maximum transmission unit (MTU) value to be used for a particular PFID. The MTU value can be 1024, 2048, or 4096. The default value is 1024 and can be used for most workloads. If you set the MTU size to 2048 or 4096, you must also enable jumbo frames on all switches in the network path for all peer hosts. For more information about the [RoCE maximum transmission unit](#), see [z/OS Communications Server: IP Configuration Guide](#).

FIXEDMEMORY *mem_size*

Specifies the maximum amount of 64-bit storage that the stack can use for the send and receive buffers that are required for SMC-R communications. The *mem_size* value is an integer in the range 30 - 9999, and represents the maximum storage in megabytes of data. The default value is 256 megabytes.

TCPKEEPMININTERVAL *interval*

This interval specifies the minimum interval that TCP keepalive packets are sent on the TCP path of an SMC-R link.

Rules:

- If a keepalive interval is also specified on the INTERVAL parameter of the TCPCONFIG statement or is set for a specific SMC-R link socket by the TCP_KEEPALIVE setsockopt() option, the largest of the three interval values is used.
- The valid range for this interval is 0-2147460 seconds, and the default is 300 seconds.
- A value of 0 disables TCP keepalive probe packets on the TCP path of an SMC-R link.
- The SO_KEEPALIVE setsockopt() option must be set for keepalive processing to be used.

Result: The TCPKEEPMININTERVAL setting has no effect on keepalive processing for the SMC-R path of an SMC-R link.

For more information about TCP keepalive processing for the TCP path and the SMC-R path of SMC-R links, see [TCP keepalive in z/OS Communications Server: IP Configuration Guide](#).

SYSPLEXMONITOR

Specifies SYSPLEXMONITOR sub parameters to configure the operation of the sysplex autonomics function. For more information about [sysplex problem detection and recovery](#), see [z/OS Communications Server: IP Configuration Guide](#).

If the SYSPLEXMONITOR parameter is not specified in the initial TCP/IP profile, then the sysplex autonomics function uses the default values for all SYSPLEXMONITOR sub parameters. If the SYSPLEXMONITOR parameter is specified but not all sub parameters are specified in the initial TCP/IP profile, then the sysplex autonomics function uses the default values for those SYSPLEXMONITOR sub parameters that are not specified. For example, if SYSPLEXMONITOR is specified without RECOVERY or NORECOVERY specified in the initial profile, then the NORECOVERY action is in effect.

Rule: If you specify the GLOBALCONFIG statement in a data set associated with a VARY TCPIP,,OBEYFILE command and the SYSPLEXMONITOR parameter is specified without any sub parameters, an informational message is issued and the parameter is ignored.

AUTOREJOIN | NOAUTOREJOIN

Specifies whether TCP/IP should automatically rejoin the TCP/IP sysplex group when a detected problem is relieved after the stack has left the sysplex group.

NOAUTOREJOIN

Do not rejoin the TCP/IP sysplex group when a detected problem is relieved. This is the default value.

AUTOREJOIN

When all detected problems (that caused the stack to leave the sysplex group) are relieved, the stack automatically rejoins the sysplex group and reprocesses the saved VIPADYNAMIC block configuration.

Restriction: AUTOREJOIN cannot be configured when NORECOVERY is configured (or set to the default value).

Guideline: AUTOREJOIN should be used when RECOVERY is configured to allow the stack to rejoin the sysplex group without operator intervention.

DELAYJOIN | NODELAYJOIN

Specify whether TCP/IP should delay joining or rejoining the TCP/IP sysplex group (EZBTCPCS) if OMPROUTE is not started and active.

NODELAYJOIN

Attempt to join the TCP/IP sysplex group without waiting for OMPROUTE to be started and active. This is the default value.

DELAYJOIN

Delay joining or rejoining the TCP/IP sysplex group and processing any VIPADYNAMIC block or DYNAMICXCF statements during stack initialization until OMPROUTE is started and active.

DELAYJOINIPSEC | NODELAYJOINIPSEC

Specify whether TCP/IP should delay joining or rejoining the TCP/IP sysplex group (EZBTCPCS) if the IPsec infrastructure is not active and operational.

NODELAYJOINIPSEC

Attempt to join the TCP/IP sysplex group without waiting for the IPsec infrastructure to be active and operational. This is the default value.

DELAYJOINIPSEC

Delay joining or rejoining the TCP/IP sysplex group and processing any VIPADYNAMIC block or DYNAMICXCF statements until the IPsec infrastructure is active and operational.

Guideline: The DELAYJOINIPSEC parameter is only relevant when Sysplex-wide Security Association (SWSA) support is enabled with the DVIPSEC parameter on the IPSEC statement. If SWSA support is not enabled, the DELAYJOINIPSEC parameter is not accepted. Message EZZ0839I is issued indicating that DELAYJOINIPSEC is ignored.

Restrictions:

- If your IPsec infrastructure includes the Network Security Services daemon (NSSD), and the IKED to NSSD connection uses a DVIPA as the source or destination IP address, do not configure DELAYJOINIPSEC.
- If you use a centralized Policy Agent server for IPsec or AT-TLS policy, and the connection from the policy client to the policy server uses a DVIPA as the source or destination IP address, do not configure DELAYJOINIPSEC.

DYNROUTE | NODYNROUTE

Specifies whether TCP/IP should monitor the presence of dynamic routes over monitored network links or interfaces.

NODYNROUTE

The TCP/IP stack should not monitor the presence of dynamic routes over monitored network links or interfaces. When MONINTERFACE is not configured, this is the default value.

DYNROUTE

The TCP/IP stack should monitor the presence of dynamic routes over monitored network links or interfaces. When MONINTERFACE is configured, this is the default value.

Tip: This level of monitoring is useful in detecting problems that OMPROUTE is having in communicating with other routing daemons on the selected network interfaces.

If no dynamic routes are present in the TCP/IP stack from that network, a specific interface attached to that network might not be active or routers attached to that network might not be active or healthy. In either case, when these conditions are detected, they provide a reasonable indication that client requests for DVIPAs or distributed DVIPAs owned by this TCP/IP stack might not reach this stack over that interface. These checks can help further qualify the state of a network interface on this TCP/IP stack. When the MONINTERFACE parameter is specified, This is the default value.

Restriction: DYNROUTE cannot be specified when NOMONINTERFACE is configured (or is the default value).

Rules:

- Specify DYNROUTE only when OMPROUTE is configured and started; otherwise, the TCP/IP stack might be forced to leave the TCP/IP sysplex group if RECOVERY is coded.
- If DYNROUTE is specified, also specify DELAYJOIN to avoid a scenario where the TCP/IP stack leaves the TCP/IP sysplex group before OMPROUTE is started.

NOJOIN

Specifies that the TCP/IP stack should not join the TCP/IP sysplex group (EZBTCPCS) during stack initialization. If this value is specified, the TCP/IP stack does not process any VIPADYNAMIC block or DYNAMICXCF statements. Any other GLOBALCONFIG SYSPLEXMONITOR parameter settings (configured or default) are ignored, and the settings are saved in case you want the TCP/IP stack to join the sysplex group at a later time.

If you subsequently issue a VARY TCPIP,,SYSPLEX,JOINGROUP command, the NOJOIN setting is overridden and the saved GLOBALCONFIG SYSPLEXMONITOR parameter settings become active. For example, if you configure NOJOIN and DELAYJOIN, DELAYJOIN is initially ignored. If you subsequently issue a V TCPIP,,SYSPLEX,JOINGROUP command, NOJOIN is overridden, DELAYJOIN becomes active, and the stack joins the sysplex group if OMPROUTE is initialized.

Similarly, if you configure NOJOIN and DELAYJOINIPSEC, DELAYJOINIPSEC is initially ignored. If you subsequently issue a V TCPIP,,SYSPLEX,JOINGROUP command, NOJOIN is overridden, DELAYJOINIPSEC becomes active, and the stack joins the sysplex group when the IPsec infrastructure is active.

Any sysplex-related definitions within the TCP/IP profile, such as VIPADYNAMIC or IPCONFIG DYNAMICXCF statements, are not processed until the TCP/IP stack joins the sysplex group.

Restriction: You can specify this parameter only in the initial profile; you cannot specify it when you issue a VARY TCPIP,,OBEYFILE command.

MONINTERFACE | NOMONINTERFACE

NOMONINTERFACE

The TCP/IP stack should not monitor the status of any network links or interfaces. This is the default.

MONINTERFACE

The TCP/IP stack should monitor the status of specified network link or interfaces. The interfaces or links being monitored are those that are configured with the MONSYSPLEX keyword on the LINK or INTERFACE statement. See [“Summary of DEVICE and LINK statements” on page 35](#) or [“Summary of INTERFACE statements” on page 80](#) for more information.

Guideline: This level of monitoring can further qualify the health of the TCP/IP stack by ensuring that at least one key interface is active and available. This option can be useful in environments

where the dynamic XCF interface is not configured as an alternate network path for this stack (for example, where no dynamic routes are advertised over dynamic XCF interfaces and no static or replaceable static routes are defined over those interfaces).

MONIPSEC | NOMONIPSEC

Specify whether TCP/IP should monitor the IPsec infrastructure after the stack has joined the sysplex group. MONIPSEC or NOMONIPSEC can only be specified as a sub parameter of DELAYJOINIPSEC.

NOMONIPSEC

The TCP/IP stack should not monitor the IPsec infrastructure after the stack has joined the sysplex group.

MONIPSEC

The TCP/IP stack should monitor the IPsec infrastructure after the stack has joined the sysplex to detect if it is not active and operational. When DELAYJOINIPSEC is configured, this is the default.

Restriction:

- If your IPsec infrastructure includes the Network Security Services daemon (NSSD), and the IKED to NSSD connection uses a DVIPA as the source or destination IP address, do not configure MONIPSEC.
- If you use a centralized Policy Agent server for IPsec or AT-TLS policy, and the connection from the policy client to the policy server uses a DVIPA as the source or destination IP address, do not configure MONIPSEC.

RECOVERY | NORECOVERY

Specify the action to be taken when a sysplex problem is detected.

NORECOVERY

When a problem is detected, issue messages regarding the problem but take no further action. This is the default value.

RECOVERY

When a problem is detected, issue messages regarding the problem, leave the TCP/IP sysplex group, and delete all DVIPA resources owned by this stack. As allowed by a configuration with backup capabilities, other members of the TCP/IP sysplex automatically take over the functions of this member that was removed from the TCP/IP sysplex group.

Recovery is the preferred method of operation because other members of the TCP/IP sysplex can automatically take over the functions of a member with no actions needed by an operator. IBM Health Checker for z/OS enhancements can be used to check whether the RECOVERY parameter has been specified when the IPCONFIG DYNAMICXCF or IPCONFIG6 DYNAMICXCF parameters have been specified. For more details about IBM Health Checker for z/OS enhancements, see [IBM Health Checker for z/OS](#) in the [z/OS Communications Server: IP Diagnosis Guide](#).

TIMERSECS seconds

Time value specified in seconds. Determines how quickly the sysplex monitor reacts to problems with needed sysplex resources. Valid values are in the range 10 - 3600 seconds. The default value is 60 seconds.

SYSPLXWLMPPOLL seconds

Time value specified in seconds. Determines how quickly the sysplex distributor and its target servers poll WLM for new weight values. A short time results in quicker reactions to changes in target status. Valid values are in the range 1 - 180 seconds. The default value is 60 seconds.

TCPIPSTATISTICS | NOTCPIPSTATISTICS

NOTCPIPSTATISTICS

Indicates that the TCP/IP counter values are not to be written to the output data set designated by the CFGPRINT JCL statement.

The NOTCPIPSTATISTICS parameter is confirmed by the message:

```
EZZ0613I TCPIPSTATISTICS IS DISABLED
```

This is the default value.

TCPIPSTATISTICS

Prints the values of several TCP/IP counters to the output data set designated by the CFGPRINT JCL statement. These counters include number of TCP retransmissions and the total number of TCP segments sent from the MVS TCP/IP system. These TCP/IP statistics are written to the designated output data set only during termination of the TCP/IP address space.

The TCPIPSTATISTICS parameter is confirmed by the message:

```
EZZ0613I TCPIPSTATISTICS IS ENABLED
```

The SMFCONFIG TCPIPSTATISTICS parameter (see “SMFCONFIG statement” on page 224) serves a different purpose. It requests that SMF records of subtype 5 containing TCP/IP statistics be created. These statistics are recorded in SMF type 118 or 119, subtype 5 records.

WLMPRIORITYQ | NOWLMPRIORITYQ

Specifies whether write priority values should be assigned to packets associated with WorkLoad Manager service classes, and to forwarded packets. See the information about prioritizing outbound OSA-Express data using the WorkLoad Manager service class importance level in [z/OS Communications Server: IP Configuration Guide](#).

NOWLMPRIORITYQ

Specifies that write priority values should not be assigned to packets associated with WorkLoad Manager service class values or to forwarded packets. This value is the default.

WLMPRIORITYQ

Specifies that write priority values should be assigned to packets associated with WorkLoad Manager service class values and to forwarded packets.

You can assign specific write priority values by using the IOPRI n sub parameters, where n is one or more of the priority values in the range 1 - 4. For each sub parameter, you can specify a control value in the range 0 - 6, which correlates to the WLM service classes, or you can specify the keyword FWD for forwarded packets. WLM supports a service class for the SYSTEM value, but this value is always assigned the write priority 1 and its assignment cannot be configured; therefore, a control value is not assigned for the SYSTEM WLM service class.

You can use the default assignment by specifying the WLMPRIORITYQ parameter without any IOPRI n sub parameters. See the description of the *default_control_values* variable in this topic to understand the default assignment.

control_values

Control values are used to represent the WLM service classes and forwarded packets. Valid control values are the digits 0 - 6, which represent WLM service classes, or the keyword FWD, which represents forwarded packets. [Table 4 on page 67](#) identifies the control value, the type of packet that it represents, and the default priority assigned to the packet:

Table 4. WLM Service Class Importance Levels		
Control value	Type of packet	Default priority queue
0	System-defined service class (SYSSTC) used for high-priority started tasks	1
1	User-defined service classes with importance level 1	2
2	User-defined service classes with importance level 2	3

<i>Table 4. WLM Service Class Importance Levels (continued)</i>		
Control value	Type of packet	Default priority queue
3	User-defined service classes with importance level 3	3
4	User-defined service classes with importance level 4	4
5	User-defined service classes with importance level 5	4
6	User-defined service classes associated with a discretionary goal	4
FWD	Forwarded packets	4

default_control_values

When the WLM `PRIORITYQ` parameter is specified without any `IOPRIIn` sub parameters, then the write priority values are assigned as shown [Table 4 on page 67](#).

IOPRIIn control_values

Use the `IOPRIIn` sub parameters to correlate control values with specific write priority values. You can use one or more of the following sub parameter keywords:

- `IOPRI1`
- `IOPRI2`
- `IOPRI3`
- `IOPRI4`

Each sub parameter keyword corresponds to one of the four write priority values, 1 through 4. Each sub parameter can be specified once on a `GLOBALCONFIG` statement.

control_values

Indicates the type of packet to which the write priority value should be assigned. Valid values are:

Digits 0 - 6

Causes the write priority value that is specified by the `IOPRIIn` sub parameter to be assigned to packets associated with the WLM service classes represented by the control value.

FWD

This keyword causes the write priority value indicated by the `IOPRIIn` sub parameter to be assigned to forwarded packets.

Rules:

- `IOPRIIn` must be followed by one or more priority level releases.
- You can specify more than one control value for an `IOPRIIn` sub parameter. Each control value must be separated by at least one blank.
- A specific control value can be specified only once in the set of `IOPRIIn` sub parameters on a `GLOBALCONFIG` statement.
- If any control value is not explicitly specified on an `IOPRIIn` sub parameter, then the associated packets are assigned a default write priority 4.

In the following example, priority 1 is assigned to packets associated with control values 0 and 1, priority 2 is assigned to packets associated with control value 2 and to forwarded packets, priority 3 is assigned to packets associated with control values 3 and 4, and priority 4 is assigned to packets associated with control values 5 and 6.

```

WLMRIORITYQ  IOPRI1 0 1
              IOPRI2 2 FWD
              IOPRI3 3 4
              IOPRI4 5 6

```

XCFGRPID *group_id*

This parameter is needed only if you want subplexing. If specified, the value provides a 2-digit suffix that is used in generating the XCF group name that the TCP/IP stack joins. Valid values are in the range 2 - 31. The group name is EZBTVvtt, where the vv value is the VTAM XCF group ID suffix (specified with the XCFGRPID VTAM start option) and the tt value is the *group_id* value supplied on this parameter, used as a 2-digit value converted to character format. If no VTAM XCF group ID suffix was specified, the group name is EZBTCPTt. If no VTAM XCF group ID suffix and no TCP XCF group ID suffix is specified, the group name is EZBTCPCS.

These characters are also used as a suffix for the EZBDVIPA and EZBEPOR structure names, in the form EZBDVIPAvt and EZBEPORvt. If no VTAM XCF group ID suffix was specified, the structure names are EZBDVIPA01t and EZBEPOR01t.

If XCFGRPID is not specified, the XCF group name is EZBTVCS and the structure names are EZBDVIPAvt and EZBEPORvt. If no VTAM XCF group id suffix was specified, the group name is EZBTCPCS and the structure names are EZBDVIPA and EZBEPOR.

Restriction: XCFGRPID can be specified only in the initial profile.

This allows multiple TCP/IP stacks to join separate Sysplex groups and access separate Coupling Facility structures, isolating sets of TCP/IP stacks into subplexes with XCF communication only with other TCP/IP stacks within the same subplex.

If HiperSockets is supported on this system, the IQDVLANID parameter, on the GLOBALCONFIG statement, must be specified if XCFGRPID is specified. Stacks on the same CPC using the same HiperSockets CHPID that specify the same XCFGRPID value must specify the same IQDVLANID value.

Stacks on the same CPC using the same HiperSockets CHPID specifying different XCFGRPID values must specify different IQDVLANID values. This allows partitioning of connectivity across the Sysplex to include partitioning of connectivity across HiperSockets.

Creating TCP/IP and VTAM subplexes can add some complexity to your VTAM and TCP/IP configurations and requires careful planning. Before setting this parameter you should review the information about [setting up a sysplex in the z/OS Communications Server: IP Configuration Guide](#).

ZERT|NOZERT

Specifies whether the z/OS Encryption Readiness Technology (zERT) will monitor TCP and Enterprise Extender traffic on this TCP/IP stack.

NOZERT

Indicates that the TCP and Enterprise Extender traffic will not be monitored by zERT. This is the default value.

ZERT

Indicates that TCP and Enterprise Extender traffic will be monitored by zERT. The zERT discovery function, which monitors and collects information about security sessions on a per-TCP- and per-EE connection basis, is always enabled when ZERT is specified. In addition, you can specify sub parameters to enable other zERT functions.

AGgregation

Indicates that the zERT aggregation function is enabled. zERT aggregation uses the information collected by zERT discovery to create summarized security session information. The zERT aggregation information is reported at fixed intervals of time, as defined by the INTVAL sub parameter. For more details on the zERT aggregation function, see [What does zERT aggregation collect?](#) in [z/OS Communications Server: IP Configuration Guide](#).

INTVal

Specifies the interval at which zERT aggregation will be reported.

SMF

Indicates the system's SMF interval is to be used. This is the default.

nn

Specifies the recording interval in one hour increments. Valid values are 1 through 24.

SYNCval hh:mm

Indicates a reference time for which zERT aggregation records will be recorded. SYNCVAL is a sub-parameter of the INTVAL sub-parameter. This field is in the form of 24 hour clock format hh:mm (hour and minute value separated by a colon). This reference time will be used to indicate the point from which the first zERT summary records should be recorded (SMF 119 subtype 12). If not specified, the default value is midnight or 00:00.

Specifies a reference time upon which INTVAL is based. The value is a time of day specified in hours and minutes in 24 hour clock format.

hh

Specifies the hour of the day, between midnight (00) and 11 PM (23).

:

Is a required separator with no intervening blanks.

mm

Specifies the minutes after the hour, between 00 and 59.

If SYNCVAL is not specified, the default is midnight (00:00).

NOAGgregation

Indicates that the zERT aggregation function is disabled. This is the default.

Note that additional configuration is required to specify where zERT data is to be written. For more information of those configuration parameters, see [“SMFCONFIG statement” on page 224](#) and [“NETMONITOR statement” on page 185](#). Separate SMFCONFIG controls exist for zERT discovery records and for zERT aggregation records.

See the [Steps for modifying](#) in this topic for details about changing this parameter while the TCP/IP stack is active.

ZIIP

Specifies sub parameters that control whether TCP/IP displaces CPU cycles onto a System z9® Integrated Information Processor (zIIP). You must specify at least one sub parameter. If the ZIIP parameter is specified with no sub parameters, an informational message is issued and the parameter is ignored.

IPSECURITY | NOIPSECURITY

Specifies whether TCP/IP should displace CPU cycles for IPsec workload to a zIIP. For more information about this function, see the [Additional IPsec assist using z9 Integrated Information Processor \(zIIP IP security\)](#) topic in [z/OS Communications Server: IP Configuration Guide](#).

NOIPSECURITY

Do not displace CPU cycles for IPsec workload to a zIIP. This is the default value.

IPSECURITY

When possible, displace CPU cycles for IPsec workload to a zIIP. Workload Manager (WLM) definitions should be examined and possible changes made before this option is used. See the more detailed description in the [Additional IPsec assist using z9 Integrated Information Processor \(zIIP IP security\)](#) topic in [z/OS Communications Server: IP Configuration Guide](#).

IQDIOMULTIWRITE | NOIQDIOMULTIWRITE

Specifies whether TCP/IP should displace CPU cycles for large outbound TCP messages that are typically created by traditional streaming work loads such as file transfer, and interactive web-based service workloads such as XML or SOAP. The TCP/IP outbound message must be at least 32KB in length before the write processing is off-loaded to an available zIIP specialty engine. For more information about this function, see the information about [HiperSockets multiple write assist with IBM zIIP](#) in [z/OS Communications Server: IP Configuration Guide](#).

NOIQDIOMULTIWRITE

Do not displace CPU cycles for the writing of large TCP outbound messages to a zIIP. This is the default value.

IQDIOMULTIWRITE

When possible, displace CPU cycles for the writing of large TCP outbound messages to a zIIP.

Rules:

- You cannot specify IQDIOMULTIWRITE as a ZIIP parameter when GLOBALCONFIG IQDMULTIWRITE is not configured. When GLOBALCONFIG IQDMULTIWRITE is not configured, HiperSockets interfaces do not use the multiple write support.
- Only large TCP outbound messages (32KB and larger) are processed on the zIIP specialty engine.
- The TCP message must be originating from this node. Routed TCP messages are not eligible for zIIP assistance.

Tip: These ZIIP parameters apply to pre-defined HiperSockets interfaces, as well as HiperSockets interfaces that are created and used by dynamic XCF definitions.

Steps for modifying

To modify parameters for the GLOBALCONFIG statement, you must respecify the statement with the new parameters.

The following list describes how to modify individual parameters:

AUTOIQDC and NOAUTOIQDC

If you use the VARY TCPIP,,OBEYFILE command to change this parameter from AUTOIQDC to NOAUTOIQDC, no new dynamic IQDC interfaces will be activated. All active dynamic IQDC interfaces will remain active and available for use. To stop existing interfaces, you must issue a V TCPIP,,STOP command for each active IQDC interface.

If you use the VARY TCPIP,,OBEYFILE command to change this parameter from NOAUTOIQDC to AUTOIQDC, active OSA interfaces are not affected, but the stack will attempt to activate a dynamic IQDC interface on any subsequent OSA activations.

AUTOIQDX and NOAUTOIQDX

If you use the VARY TCPIP,,OBEYFILE command to change this parameter from AUTOIQDX to NOAUTOIQDX, no new dynamic IQDX interfaces will be activated. All active dynamic IQDX interfaces will remain active and available for use. To stop existing interfaces, you must issue a V TCPIP,,STOP command for each active IQDX interface.

If you use the VARY TCPIP,,OBEYFILE command to change this parameter from NOAUTOIQDX to AUTOIQDX, active OSX interfaces are not affected, but the stack will attempt to activate a dynamic IQDX interface on any subsequent OSX activations.

EXPLICITBINDPORTRANGE and NOEXPLICITBINDPORTRANGE

If you specified the EXPLICITBINDPORTRANGE parameter and then you change to the NOEXPLICITBINDPORTRANGE parameter, then the stack stops allocating more ports from the EXPLICITBINDPORTRANGE pool. However, the existing active range for the EXPLICITBINDPORTRANGE pool in the coupling facility is unaffected unless you are changing the parameter on the last stack in the sysplex using this function.

If you specified the NOEXPLICITBINDPORTRANGE parameter and then you change to the EXPLICITBINDPORTRANGE parameter, then a range of ports used for the EXPLICITBINDPORTRANGE pool is set. The stack uses ports from that pool for explicit bind() requests to the IPv4 INADDR_ANY address, or to the IPv6 unspecified address (in6addr_any), and port 0. If the range specified on the EXPLICITBINDPORTRANGE parameter is different from the currently active range for the EXPLICITBINDPORTRANGE pool in the coupling facility, the new range replaces that value.

Changing the starting port (*1st_port*), the number of ports (*num_ports*), or both for the EXPLICITBINDPORTRANGE parameter changes the port numbers in the pool of ports that is guaranteed to be unique across the sysplex for future port allocation

Guidelines:

- Changing the range specified on the EXPLICITBINDPORTRANGE parameter of the GLOBALCONFIG statement affects every stack in the sysplex that has configured a GLOBALCONFIG EXPLICITBINDPORTRANGE value. Future port allocations for all such stacks use the new port range.
- Ports in the EXPLICITBINDPORTRANGE range are usually assigned to a stack in blocks of 64 ports. When expanding the range, use multiples of 64 multiplied by the number of stacks that use a GLOBALCONFIG EXPLICITBINDPORTRANGE configuration.

IQDMULTIWRITE and NOIQDMULTIWRITE

If this parameter is changed with the VARY TCPIP,,OBEYFILE command, the new value does not take effect for any active HiperSockets (iQDIO) interfaces. For a change in this parameter to take effect for an active iQDIO interface, you must stop and restart both the IPv4 and IPv6 interface for the change to be effective.

IQDVLANID

If the IQDVLANID parameter was previously specified and you modify that value, then you must stop and restart the TCP/IP stack for the change to take effect.

MLSCHKTERMINATE

You cannot change the MLSCHKTERMINATE parameter to the NOMLSCHKTERMINATE parameter when the RACF option MLSTABLE is on and the RACF option MLQUIET is off. You can always change the NOMLSCHKTERMINATE parameter to the MLSCHKTERMINATE parameter, but this change is ignored if the value is specified in the data set of a VARY TCPIP,,OBEYFILE command and consistency errors are detected at the same time.

SEGMENTATIONOFFLOAD and NOSEGMENTATIONOFFLOAD

If this parameter is changed with the VARY TCPIP,,OBEYFILE command, the new value does not take effect for any active OSA interfaces. For a change in these parameters to take effect, all the OSA interfaces that support TCP segmentation offload must be stopped and restarted.

SMCD and NOSMCD

- If SMC-D support is not enabled, you can specify the SMCD parameter in a VARY TCPIP,,OBEYFILE command data set to activate the support.

Result: TCP/IP retains knowledge of the last set of SMCD sub parameter values that are specified on the GLOBALCONFIG statement, even if GLOBALCONFIG NOSMCD was specified subsequently. If you issue a VARY TCPIP,,OBEYFILE command with GLOBALCONFIG SMCD specified, TCP/IP uses the last saved set of SMCD sub parameters, unless new values for the sub parameters are coded on the GLOBALCONFIG SMCD statement. Therefore, you can temporarily stop SMC-D processing by issuing a VARY TCPIP,,OBEYFILE command with GLOBALCONFIG NOSMCD specified. Then you can resume SMC-D processing with the previous sub parameter settings by issuing a second VARY TCPIP,,OBEYFILE command with just GLOBALCONFIG SMCD specified. Specifying the SMCD parameter also causes the AUTOCACHE function and AUTOSMC monitoring function to be restarted if the SMCGLOBAL AUTOCACHE and AUTOSMC parameters are enabled.

- If SMC-D support is enabled, you can specify the NOSMCD parameter in a VARY TCPIP,,OBEYFILE command data set to deactivate the support.
 - No new TCP connections that use SMC-D processing will be established.
 - Existing TCP connections that use SMC-D will continue to use SMC-D processing.
 - The AUTOCACHE function will be stopped if SMC-R processing is not active.
 - The AUTOSMC monitoring function will be stopped if SMC-R processing is not active.

SMCGLOBAL

AUTOCACHE and NOAUTOCACHE

If you use the VARY TCPIP,,OBEYFILE command to change this parameter from AUTOCACHE to NOAUTOCACHE, the following actions occur:

- Destination IP addresses cached not to use SMC will be deleted from the cache.
- The stack will not cache unsuccessful attempts to create an SMC-R or SMC-D link per destination IP address for new TCP connections.

If you use the VARY TCPIP,,OBEYFILE command to change this parameter from NOAUTOCACHE to AUTOCACHE, the SMCGLOBAL AUTOCACHE function is enabled.

SMCEID/ENDSMCEID

If you specify SMCEID-ENDSMCEID block with the VARY TCPIP,,OBEYFILE command, the values are changed to the data set that contains the new user EID values. All existing definitions for SMCEID-ENDSMCEID block will be fully replaced with the new definitions immediately. Specifying SMCEID-ENDSMCEID block while SMCv2 is disabled will enable both SMC-Dv2 and SMC-Rv2. Specifying SMCEID-ENDSMCEID block with no values will disable SMC-Rv2; it will also disable SMC-Dv2 if NOSYSTEMEID is in effect.

SYSTEMEID/NOSYSTEMEID

If SYSTEMEID has previously been configured and you then specify NOSYSTEMEID with the VARY TCPIP,,OBEYFILE command, SMC-Dv2 will be disabled. If NOSYSTEMEID has previously been configured and you then specify SYSTEMEID with the VARY TCPIP,,OBEYFILE command, SMC-Dv2 will be activated.

SMCPERMIT/ENDSMCPERMIT

If you specify SMCPERMIT-ENDSMCPERMIT block with the VARY TCPIP,,OBEYFILE command, the values are changed to the data set that contains a new SMCPERMIT-ENDSMCPERMIT values. All existing definitions for SMCPERMIT-ENDSMCPERMIT block will be fully replaced with the new definitions immediately.

SMCEXCLUDE/ENDSMCEXCLUDE

If you specify SMCEXCLUDE - ENDSMCEXCLUDE block with the VARY TCPIP,,OBEYFILE command, the values are changed to the data set that contains a new SMCEXCLUDE - ENDSMCEXCLUDE values. All existing definitions for SMCEXCLUDE - ENDSMCEXCLUDE block will be fully replaced with the new definitions immediately.

SMCR and NOSMCR

- If SMCR support is not enabled, you can specify the SMCR parameter in a VARY TCPIP,,OBEYFILE command data set to activate the support.

Result: TCP/IP retains knowledge of the last set of SMCR sub parameter values that are specified on the GLOBALCONFIG statement, even if GLOBALCONFIG NOSMCR was specified subsequently. If you issue a VARY TCPIP,,OBEYFILE command with GLOBALCONFIG SMCR specified, TCP/IP uses the saved last set of SMCR sub parameters, unless new values for the sub parameters are coded on the GLOBALCONFIG SMCR statement. This allows you to temporarily stop SMC-R processing by issuing a VARY TCPIP,,OBEYFILE command with GLOBALCONFIG NOSMCR specified. Then you can resume SMC-R processing with the previous sub parameter settings by issuing a second VARY TCPIP,,OBEYFILE command with just GLOBALCONFIG SMCR specified. Specifying the SMCR parameter also causes the AUTOCACHE function and AUTOSMC monitoring function to be restarted if the SMCGLOBAL AUTOCACHE and AUTOSMC parameters are enabled.

- If SMCR support is enabled, you can specify the NOSMCR parameter in a VARY TCPIP,,OBEYFILE command data set to deactivate the support.
 - No new TCP connections that use SMC-R processing will be established.
 - Existing TCP connections that use SMC-R will continue to use SMC-R processing.
 - The AUTOCACHE function will be stopped if SMC-D processing is not active.
 - The AUTOSMC monitoring function will be stopped if SMC-D processing is not active.

- You cannot change the SMCR PFID parameter values that are currently configured when the associated *RoCE* interfaces are active. To change the SMCR PFID parameter values that are currently configured, you must perform the following steps in order:
 1. Stop the associated *RoCE* interface.
 2. Issue the VARY TCPIP,,OBEYFILE command with the new PFID values that are coded in the command data set. The new PFID values replace the existing PFID values.
- To add PFID values when you have one or more PFID values coded, you must specify the existing PFID values and the additional PFID values on the SMCR parameter in the VARY TCPIP,,OBEYFILE command data set. Existing PFID values and any existing *RoCE* interfaces are not affected.

SYSPLEXMONITOR

AUTOREJOIN and NOAUTOREJOIN

If you change NOAUTOREJOIN to AUTOREJOIN after the stack has left the sysplex and before the problem that caused it to leave has been relieved, the stack automatically rejoins the sysplex group when the problem is relieved. However, if you change NOAUTOREJOIN to AUTOREJOIN after the problem that caused the stack to leave the group has been relieved, you must issue a VARY TCPIP,,SYSPLEX,JOINGROUP command to cause the stack to rejoin the sysplex.

DELAYJOIN and NODELAYJOIN

Changing from DELAYJOIN to NODELAYJOIN while the TCP/IP stack is in the process of delaying joining the sysplex group because OMROUTE is not active causes the TCP/IP stack to immediately join the sysplex group.

Changing from NODELAYJOIN to DELAYJOIN has no immediate effect until the TCP/IP stack leaves the sysplex group and then attempts to rejoin while OMROUTE is not active.

DELAYJOINIPSEC and NODELAYJOINIPSEC

Changing from DELAYJOINIPSEC to NODELAYJOINIPSEC while the TCP/IP stack is in the process of delaying joining the sysplex group because the IPsec infrastructure is not active causes the TCP/IP stack to immediately join the sysplex group.

Changing from NODELAYJOINIPSEC to DELAYJOINIPSEC NOMONIPSEC has no immediate effect until the TCP/IP stack leaves the sysplex group and then attempts to rejoin while the IPsec infrastructure is not active.

Changing from NODELAYJOINIPSEC to DELAYJOINIPSEC with MONIPSEC configured or defaulted activates monitoring of the IPsec infrastructure.

MONIPSEC and NOMONIPSEC

Changing from MONIPSEC to NOMONIPSEC after the TCP/IP stack has detected a problem with the IPsec infrastructure does not clear message EZD1977E or cause the TCP/IP stack to rejoin the sysplex group (if RECOVERY had caused it to leave the sysplex). If you want the TCP/IP stack to rejoin the sysplex group, you must issue a VARY TCPIP,,SYSPLEX,JOINGROUP command.

Changing from NOMONIPSEC to MONIPSEC activates monitoring of the IPsec infrastructure.

SYSPLEXWLM POLL

You can change the polling rate for WLM values while the TCP/IP stack is active. In order for the change to be effective, you should change the polling rate on all stacks that participate in sysplex distribution (all active distributing stacks, any backup stacks that might take over distribution, and all target stacks).

WLM PRIORITYQ

If you specify WLM PRIORITYQ with the VARY TCPIP,,OBEYFILE command, the IOPRI n values are changed to the values specified for the *default_control_values* variable. The new values take effect immediately for all workloads influenced by this function.

WLM PRIORITYQ IOPRI n control_values

If you specify this parameter with the VARY TCPIP,,OBEYFILE command, and you do not specify all the control values, the priority 4 is assigned to packets associated with all control values omitted. The new values immediately take effect for all workloads influenced by this function.

Rule: You cannot modify individual IOPRIn control values. If you attempt to modify IOPRIn control values, but you specify only those control values that you want to modify, then the priority 4 is assigned to packets that are associated with any control values that you omitted.

XCFGRPID

For a change in this parameter to take effect, you must stop and restart the TCP/IP stack.

ZERT|NOZERT

If you use the VARY TCPIP,,OBEYFILE command to change INTVAL, zERT aggregation will flush the existing records and begin for new TCP and Enterprise Extender connections, with a new INTVAL. If not specified, the default value for INTVAL is SMF (which is the SMF interval time).

If you use the VARY TCPIP,,OBEYFILE command to change SYNCVAL, zERT aggregation will flush the existing records and will begin for new TCP and Enterprise Extender connections, with a new SYNCVAL (INTVAL always has to be specified since SYNCVAL is a sub-parameter of INTVAL). If not specified, the default time for SYNCVAL is 00:00 which is midnight.

If you use the VARY TCPIP,,OBEYFILE command to change this parameter from ZERT to NOZERT then all ZERT discovery and aggregation functions stop. In addition, all zERT SMF recording stops and all collected data is discarded.

If you use the VARY TCPIP,,OBEYFILE command to change this parameter from NOZERT to ZERT then zERT discovery will begin for new TCP and Enterprise Extender connections only. TCP and Enterprise Extender connections that existed before zERT discovery was enabled will not be monitored. The zERT aggregation function remains disabled.

If you use the VARY TCPIP,,OBEYFILE command to change this parameter from NOZERT to ZERT AGGREGATION, then both the zERT discovery and aggregation functions will begin for new TCP and Enterprise Extender connections only. TCP and Enterprise Extender connections that existed before zERT was enabled will not be monitored, nor will they be included in the aggregation function statistics.

If you use the VARY TCPIP,,OBEYFILE command to change the sub parameter from ZERT NOAGGREGATION to ZERT AGGREGATION, then zERT aggregation will begin for new TCP and Enterprise Extender connections only. TCP and Enterprise Extender connections that existed before zERT aggregation was enabled will not be included in the summarized data. The zERT discovery function is not affected.

If you use the VARY TCPIP,,OBEYFILE command to change the sub parameter from ZERT AGGREGATION to ZERT NOAGGREGATION, then the zERT aggregation function stops, although zERT discovery continues. All zERT summary information is discarded and one final set of zERT summary records is generated.

Examples

This example shows the use of the SYSPLEXMONITOR parameter on the GLOBALCONFIG statement that enables many of the sysplex autonomies functions:

```
GLOBALCONFIG SYSPLEXMONITOR AUTOREJOIN DELAYJOIN MONINTERFACE DYNROUTE RECOVERY
```

The following example shows the use of the EXPLICITBINDPORTRANGE parameter to define 1024 ports in the range 5000 - 6023. The ports are used for explicit binds to the IPv4 INADDR_ANY address, or to the IPv6 unspecified address (in6addr_any), and port 0:

```
GLOBALCONFIG EXPLICITBINDPORTRANGE 5000 1024
```

The following examples shows the use of the SMCR parameter to define two RoCE features that use PFID values 0018 and 0019 and port numbers 1 and 2, and to limit the stack to 500 megabytes of 64-bit storage for SMC-R communications. The first example represents 10 GbE RoCE Express features and the second example represents RoCE Express2/RoCE Express3 features.

```
GLOBALCONFIG SMCR PFID 0018 PORTNUM 1 PFID 0019 PORTNUM 2 FIXEDMEMORY 500
```

Parameters

internet_addr

The IP address valid for this host. The IP address can be associated with a physical or VIPA link.

Requirement: The IP address must be specified in dotted decimal form.

link_name

The name of the link defined in a previous LINK statement (or the reserved name LOOPBACK) that is associated with the home address.

Steps for modifying

To modify the HOME statement, use a VARY TCPIP,,OBEYFILE command with a data set that defines a new HOME statement.

Rules:

- If you use the HOME statement to change the IP addresses of any links, you should stop and restart the affected devices. Furthermore, if the OSPF dynamic routing protocol is being used over an affected interface, you should wait between stopping and restarting the device to enable the OSPF protocol to fully propagate the deletion of the old IP address. The duration of this wait should be at least three times the dead router interval configured for the interface.
- The first HOME statement of each configuration data set that is set replaces the existing HOME list with the new list. Subsequent HOME statements in the same data set add entries to the list; however, dynamically defined HOME list entries created by XCF dynamics, by a VIPADefine statement, or by an application binding to an IP address in a currently valid VIPARANGE statement are not deleted by a new HOME statement. You can display dynamically created HOME list entries with the Netstat HOME/-h command. A dynamic XCF HOME list entry has the link name EZASAMEMVS or begins with EZAXCF. A dynamic VIPA HOME list entry has a link name that begins with VIPL, followed by the hexadecimal value of its IP address.
- If the first HOME statement of a profile contains no entries, then all IP addresses that were specified in a HOME statement from a previous profile are removed from the HOME list.
- If you change the IP address of a link that was used by previously specified default routes and you want to maintain those default routes, you must include your BEGINROUTES statement for those default routes in the VARY TCPIP,,OBEYFILE command data set that contains the new HOME list. If you do not include your BEGINROUTES statement, the static routes using that link are deleted.
- If you had previously specified the PRIMARYINTERFACE statement and want to preserve the primary interface that was previously specified, you must include your PRIMARYINTERFACE statement in the VARY TCPIP,,OBEYFILE command data set that contains the new HOME list. If you do not include the original PRIMARYINTERFACE statement, the primary interface is reset to the first entry in the new HOME list.

Usage notes

- Only one home address can be associated with a link. If the same link is specified in more than one HOME list entry, only the home address in the last entry is associated with the link. The only exception to this is the LOOPBACK link.
- The default LOOPBACK address of 127.0.0.1 is internally defined by the TCP/IP stack. If you try to define this LOOPBACK address, it is flagged as a duplicate entry. You can use a *link_name* value of LOOPBACK in the HOME list to define additional LOOPBACK addresses. No DEVICE or LINK statement is needed for LOOPBACK, and it cannot be started or stopped (LOOPBACK is always active).
- IP addresses from 127.0.0.128 through 127.0.0.255 are reserved for IBM use and cannot be coded on the HOME statement as the IP address of any link; this includes LOOPBACK addresses.
- To improve server application performance, use a non-loopback home address instead of a loopback address. This can result in improved throughput for applications that reside on the same MVS system and communicate with one another on the same TCP/IP stack.

- If a default local address is not specified using the PRIMARYINTERFACE statement, the first address in the HOME list is used as the default local address. This default local address is the value obtained by the GETHOSTID() function.
- If an outgoing packet has the limited broadcast address (255.255.255.255) as its destination address and the source address is not specified by the sender, the default local address (see previous bullet) is used as the source address as long as it is associated with a link (other than LOOPBACK) that supports broadcast. If the link associated with the default local address is LOOPBACK or it does not support broadcast, the first address in the HOME list that is associated with a link (other than LOOPBACK) that supports broadcast is used as the source address.
- When an incorrect HOME entry is encountered, all entries following that entry on that HOME statement are ignored. Subsequent HOME statements are processed.
- When defining static VIPA addresses, observe the following rules:
 - Code a primary VIPA address first in the HOME list or on the PRIMARYINTERFACE statement to serve as the default local address for use by the GETHOSTID() function.

A static VIPA address must be a unique host address in the network and not be a duplicate of any physical IP address in the network.

If using the RIP routing protocol and host route broadcasting is not supported by adjacent routers (that is, adjacent routers are unable to learn host routes), the following restrictions for VIPA addresses must be applied in order to benefit from fault tolerance support:

- If you use subnetting and VIPA addresses are in the same network as the physical IP addresses, the subnetwork portion of any VIPA addresses must not be the subnetwork portion of any physical IP addresses in the network. In this case, assign a new subnetwork for the VIPA address.

If subnetting is not used on any physical interface, the network portion of any VIPA address must not be the network portion of any physical IP address in the network. In this case, assign a new network for the VIPA address, preferably a class C network address.

If using the RIP routing protocol and host route broadcasting is supported by adjacent routers (that is, adjacent routers are able to learn host routes), the network or subnetwork portions of VIPA addresses can be the same across multiple z/OS TCP/IP stacks in the network. See [Chapter 11, “OMPROUTE,” on page 429](#) for more information.

While a VIPA address can be assigned to each TCP/IP stack in one z/OS image, you should define an internal point-to-point link (for example, CTC) between the stacks. This ensures that the VIPA address in one z/OS TCP/IP stack attached to a failing adapter/controller (for example, 3172) can be reached by way of another z/OS TCP/IP stack channel-attached to the same controller through another adapter or to another controller across the point-to-point link.

For information about what routing protocols to use to achieve nondisruptive TCP-connection fault tolerance, see the VIPA information in [z/OS Communications Server: IP Configuration Guide](#).

If you are using a name server to resolve host names by way of UDP and any of the related resolver configuration files have only one name server address coded that specifies a VIPA address, the host the name server is running on must be configured to use the SOURCEVIPA option.

- In general, the static VIPA addresses can be coded in any order in the HOME list; however, if you specify the SOURCEVIPA option on the IPCONFIG statement, the order of the VIPA addresses is important in terms of how source IP addresses are used for outbound datagrams originating at the host. In this case, the following rules apply:
 - In the HOME list, the static VIPA address that precedes a physical IP address is used as the source IP address if not overridden by another method of source address selection. See the information about source IP address selection in [z/OS Communications Server: IP Configuration Guide](#) for the hierarchy of ways that the source IP address of an outbound packet is determined.
 - If static VIPA addresses are coded after all of the physical IP addresses, no VIPA addresses are used as the source IP address.
- More than one VIPA address can be defined in one network or subnetwork.

- You can use the VIPA address as the primary or only destination for the name of a z/OS server on the domain name server. A workstation on the network would use the z/OS server name (translated into the VIPA address) to access applications on the z/OS server.
- If you use DEVICE and LINK statements to define an IPv4 interface and you want to designate a static VIPA as the source VIPA for that interface, use DEVICE and LINK statements to define the static VIPA.
- If you use the INTERFACE statement to define an IPv4 interface and you want to designate a static VIPA as the source VIPA for that interface, take the following steps:
 - Use the INTERFACE VIRTUAL statement to define the static VIPA that will be used as the source VIPA.
 - Specify the SOURCEVIPAINTERFACE parameter on the INTERFACE statement for the IPv4 interface.

Examples

This example shows a HOME statement that defines the IP addresses of each link in the host.

```
HOME
 151.4.1.2    ETH3
 192.1.1.1    VIPA1
 193.5.2.1    ETH1
 192.2.1.1    VIPA2
 193.7.2.1    SNA1
```

VIPA1 and VIPA2 are examples of static VIPA links associated with static VIPA addresses, the other values are examples of physical links associated with physical IP addresses. If you specify SOURCEVIPA on the IPCONFIG statement, VIPA1 serves as the VIPA address for ETH1, and VIPA2 for link SNA1. Because there is no VIPA definition preceding ETH3 in the HOME list, it is not affected by SOURCEVIPA. The VIPA addresses are used in the outbound IP datagrams. For more information, see [“IPCONFIG statement” on page 143](#).

The following example shows the definition of an additional LOOPBACK address:

```
HOME  9.67.113.105  CTCD00 ; CTC IP address for this system
      127.0.0.2     LOOPBACK ; additional LOOPBACK address
```

If using the SOURCEVIPA option for the outbound datagrams originating at a z/OS TCP/IP stack, see the following example for details:

```
HOME
 172.2.1.1    VIPA1 ; <-- Source for ETH1
 151.2.3.1    ETH1
 172.2.1.2    VIPA2 ; <-- Source for ETH2
 151.2.3.2    ETH2
```

Select a VIPA address in the HOME statement to provide as the local address. The address that closely precedes a physical IP address is used as the local address. For example:

Optionally, additional VIPA addresses can be defined to associate a group of interfaces and serve as local addresses. In this example, VIPA1 is associated with ETH1, and VIPA2 is associated with ETH2.

If an outbound datagram is not to contain a SOURCEVIPA address for a particular interface (that is, use a physical IP address), then use the following example:

```
HOME
 151.4.1.2    ETH3 ; <-- No SOURCEVIPA for outbound on ETH3
 172.2.1.1    VIPA ; <-- Source for ETH1
 151.2.3.1    ETH1
```

If traffic over an interface should not use a source VIPA address, put the HOME entry for that interface before all VIPA addresses in the HOME list.

- See the SOURCEVIPA information in [“IPCONFIG statement” on page 143](#).

INCLUDE statement

This statement causes profile statements from the named data set to be included at the point that the INCLUDE statement is encountered. In general, a profile statement must begin and end within the same data set. For example, the statement beginning with BSDROUTINGPARMS and ending with ENDBSDROUTINGPARMS must be contained within the same data set.

Syntax

➤ INCLUDE — *data_set_name* ➤

Parameters

data_set_name

A fully qualified data set name that identifies a sequential file. The sequential file can be a sequential data set or a PDS with the member name. It cannot be a z/OS UNIX file.

Steps for modifying

Modification is not applicable to this statement.

Summary of INTERFACE statements

Use the INTERFACE statement to define an IPv4 or IPv6 interface for OSA Ethernet. You can also use the INTERFACE statement to define an interface for Hipersockets or static VIPA

See [“Summary of DEVICE and LINK statements” on page 35](#) for IPv4 support for other interface types.

[Table 5 on page 80](#) summarizes information about the IPv4 network interface types supported by TCP/IP with the INTERFACE statement.

Table 5. IPv4 network interface types supported by TCP/IP						
Interface type	Connectivity	ID in TCP/IP profile	MTU	TRLE definition	DYNAMICXCF support	64-bit support (see Note 3 in Table 6 on page 81)
EQENET	LAN by way of Network Express in Enhanced QDIO mode (Gigabit Ethernet, 10G, 25G)	DEVNUM	9000	Automatically generated by VTAM	No	Exploitation

<i>Table 5. IPv4 network interface types supported by TCP/IP (continued)</i>						
Interface type	Connectivity	ID in TCP/IP profile	MTU	TRLE definition	DYNAMICXCF support	64-bit support (see Note 3 in Table 6 on page 81)
IPAQENET	LAN by way of OSA in QDIO mode (Gigabit Ethernet, 10G, or Fast Ethernet), 1000BASE-T Ethernet	OSA port name	8992 (1492 for Fast Ethernet)	Required	No	Exploitation
IPAQIDIO	Another TCP/IP within same CPC	CHPID	57344 Note: Based on frame size configured in HCD.	Reserved name	Yes	Exploitation

Table 6 on page 81 summarizes information about the IPv6 network interface types supported by TCP/IP.

<i>Table 6. IPv6 network interface types supported by TCP/IP</i>						
Interface type	Connectivity	ID in TCP/IP profile	MTU	TRLE definition	DYNAMICXCF support	64-bit support (3)
EQENET6	LAN by way of Network Express in Enhanced QDIO mode (Gigabit Ethernet, 10G, 25G)	DEVNUM	9000	Automatically generated by VTAM	No	Exploitation
IPAQENET6	LAN by way of OSA in QDIO mode (Gigabit Ethernet, 10G, 1000BASE-T, or Fast Ethernet)	OSA port name	9000 (1500 for Fast Ethernet)	Required	No	Exploitation
IPAQIDIO6	Another TCP/IP within same CPC	CHPID	57344 (2)	Reserved name	Yes	Exploitation
MPCPTP6 for ESCON	ESCON to another z/OS Communications Server image, running IPv6 at z/OS level V1R5 or later.	TRLE Name	59392 (1)	Manual definition required	No	Compatibility

Table 6. IPv6 network interface types supported by TCP/IP (continued)						
Interface type	Connectivity	ID in TCP/IP profile	MTU	TRLE definition	DYNAMICXCF support	64-bit support (3)
MPCPTP6 for XCF	Coupling Facility or ESCON channel to another z/OS Sysplex member running IPv6 at z/OS level V1R5 or later.	CP name of target VTAM	55296	Automatically generated by VTAM	Yes	Compatibility
MPCPTP6 (for IUTSAMEH)	Simulated IPv6 channel to another TCP/IP (or to VTAM, for Enterprise Extender) on same z/OS image.	IUTSAMEH	65535	Automatically generated by VTAM	Yes	Compatibility
Notes: <ol style="list-style-type: none"> Based on MAXBFRU value in the TRLE definition. Based on frame size configured in HCD. The TCP/IP stack exploits 64-bit virtual storage. TCP/IP device drivers have two levels of 64-bit support: <ul style="list-style-type: none"> 64-bit compatibility means that the device does not exploit 64-bit virtual storage but is compatible with the 64-bit TCP/IP stack. Additional copies of incoming and outgoing data between stack 64-bit virtual storage and device driver 64-bit virtual storage might be required. This might affect CPU and performance. The impact, if any, is based on the characteristics of your specific workloads such as message size and patterns, and environment. This is primarily an issue for streaming or bulk workloads. 64-bit exploitation means that the device fully exploits 64-bit virtual storage and does not require additional copies between stack 64-bit virtual storage and device driver 64-bit virtual storage. 						

The stack supports one IPv4 home address per interface. The stack does not impose any limit on the number of IPv6 home addresses allowed for a given interface.

Statement dependency

The INTERFACE statement for an IPv6 interface type is rejected unless the stack is enabled for IPv6. To enable the stack for IPv6, see [z/OS Communications Server: IPv6 Network and Appl Design Guide](#) for information about defining TCP/IP as a UNIX System Services physical file system (PFS).

Modifying INTERFACE statements

To modify most INTERFACE statement parameters, you must first delete and redefine the INTERFACE statement.

However, the following INTERFACE statement parameters are dynamically modifiable:

- MONSYSPLEX

- NOMONOSYSPLEX

To modify these parameters on an INTERFACE statement, use a VARY TCPIP,,OBEYFILE command with a data set that contains an INTERFACE statement for an existing interface name which has new values for these parameters.

Restrictions:

- Any changes to non-modifiable parameters are ignored
- If any modifiable parameters are not specified, prior values remain in effect for these parameters

Restrictions on IPv6 addresses configured in the TCP/IP profile

The following IPv6 addresses are not accepted for *ipaddr_spec*:

- Link local IP addresses
- Multicast IP addresses
- IPv4-mapped IPv6 addresses
- Addresses with the reserved prefix `::/96`
- Default loopback address `::1`
- Unspecified address `::`
- Any address where bit 6 (the universal/local flag - 'U' bit) or bit 7 (the group/individual flag - 'G' bit) of the Interface ID portion is nonzero.

The Interface ID portion is the lower 64 bits of the address. The Interface ID bit positions are numbered 0 - 63. This is shown in the following code example:

		1 1		3 3		4 4		6
0		5 6		1 2		7 8		3
+	-----	+	-----	+	-----	+	-----	+
	xxxxxx	UGxxxxxx		xxxxxxxxxxxxxxxx		xxxxxxxxxxxxxxxx		xxxxxxxxxxxxxxxx
+	-----	+	-----	+	-----	+	-----	+

- ISATAP address ('00005EFE'x in bits 0 - 31 of the Interface ID portion of the address).
- Reserved Anycast address (Non-multicast format prefix 001 - - 111 and 'FCFFFFFFFFFFFF8'x in bits 0 - 56 of the Interface ID portion of the address. The format prefix is the bit string consisting of the first 3 bits of the address.)
- A site-local address that has any value other than 0 in bits 10 - 47 of the address. (A site-local address has 1111111011 in bits 0 - 9 of the address.)

Guideline: Site-local addresses were designed to use private address prefixes that could be used within a site without the need for a global prefix. Until recently, the full negative impacts of site-local addresses in the Internet were not fully understood. Because of problems in the use and deployment of addresses constructed using a site-local prefix, the IETF has deprecated the special treatment given to the site-local prefix. An IPv6 address constructed using a site-local prefix is now being treated as a global unicast address. The site-local prefix might be reassigned for other use by future IETF standards action.

You should not use site-local unicast addresses. Instead of site-local addresses, you should use global unicast addresses.

Steps for modifying INTERFACE statements

This topic describes the steps for modifying the INTERFACE statement.

Procedure

Perform the following steps to modify all other parameters (other than MONOSYSPLEX and NOMONOSYSPLEX) on an INTERFACE statement:

1. Stop the interface.

Ignore this step if the device is for a static VIPA because it cannot be stopped.

2. Use a VARY TCPIP,,OBEYFILE command with a data set that contains: `INTERFACE interface_name
DELETE statement`

Result: The stack deletes all static routes that reference the name of the deleted interface.

For more information about the [VARY TCPIP Command](#), see [z/OS Communications Server: IP System Administrator's Commands](#).

3. Use a VARY TCPIP,,OBEYFILE command with a data set that contains the changed INTERFACE statement.

If you were using static routes that referenced the name of the deleted interface, then this data set should also contain a BEGINROUTES block with your complete set of static route definitions.

Rule: The data set that you use on the VARY TCPIP,,OBEYFILE command in this step should be different from the data that you used in Step 2. Do not attempt to delete and redefine an interface in the same OBEYFILE data set.

4. Start the interface.

Ignore this step if the device is for a static VIPA. A static VIPA becomes active after its interface is added in step 3.

What to do next

To modify IPADDR values for an IPAQENET6 interface, use INTERFACE ADDADDR and INTERFACE DELADDR.

To modify TEMPPREFIX for an IPAQENET6 interface, use INTERFACE ADDTEMPPREFIX and INTERFACE DELTEMPPREFIX.

Monitoring network interfaces (INTERFACE statements)

To delete interfaces, stop the interfaces first. When the interfaces are stopped, they become inactive. If the TCP/IP stack is currently monitoring interfaces and detects that all monitored interfaces are inactive as a result of stopping devices, the TCP/IP stack might issue messages regarding the problem and might trigger a recovery action. You can disable monitoring these interfaces. Specify the NOMONSYSPLEX keyword on the INTERFACE statement using the VARY TCPIP,,OBEYFILE command before stopping the interfaces. For more information about sysplex autonomics, see [sysplex problem detection and recovery](#) in [z/OS Communications Server: IP Configuration Guide](#).

INTERFACE - IPAQENET OSA-Express QDIO interfaces statement

Use the INTERFACE statement to specify an OSA-Express QDIO Ethernet interface for IPv4.

Restriction: This statement applies to IPv4 IP addresses only.

To determine the OSA microcode level, use the DISPLAY TRL command. If a specific OSA function is documented with a minimum microcode level, you can use this command to determine whether that function is supported. IBM service might request the microcode level for problem diagnosis. For more information about the [DISPLAY TRL command](#), see [z/OS Communications Server: SNA Operation](#).

For more information about OSA features that support QDIO mode, see <https://www.ibm.com/docs/en/zos/2.3.0?topic=osa-z-systems-express-customers-guide-reference>.

When you start an IPAQENET interface (and you did not specify VMAC with ROUTEALL), TCP/IP registers all non-loopback local (home) IPv4 addresses for this TCP/IP instance to the OSA feature. If you subsequently add, delete, or change any home IPv4 addresses on this TCP/IP instance, TCP/IP dynamically registers the changes to the OSA feature. The OSA adapter routes datagrams destined for those IPv4 addresses to this TCP/IP instance.

If a datagram is received at the OSA adapter for an unregistered IPv4 address, then the OSA feature routes the datagram to the TCP/IP instance, depending on the setting of a virtual MAC (VMAC) address or definition of an instance as PRIROUTER or SECROUTER. If the datagram is not destined for a virtual MAC address and no active TCP/IP instance using this interface is defined as PRIROUTER or SECROUTER, then the OSA feature discards the datagram. See the [router information in z/OS Communications Server: IP Configuration Guide](#) for more details and [primary and secondary routing in z/OS Communications Server: SNA Network Implementation Guide](#).

For detailed instructions on setting up an OSA feature, see <https://www.ibm.com/docs/en/zos/2.3.0?topic=osa-z-systems-express-customers-guide-reference>.

For more information about missing interrupt handler (MIH) considerations with TCP/IP interfaces, see “Missing interrupt handler factors” on page 37.

Tip: For a list of all related OSA Express Best Practices for optimizing your performance for your OSA interface configuration, see [IBM z/OS Communications Server and OSA Express Best Practices](#).

Syntax

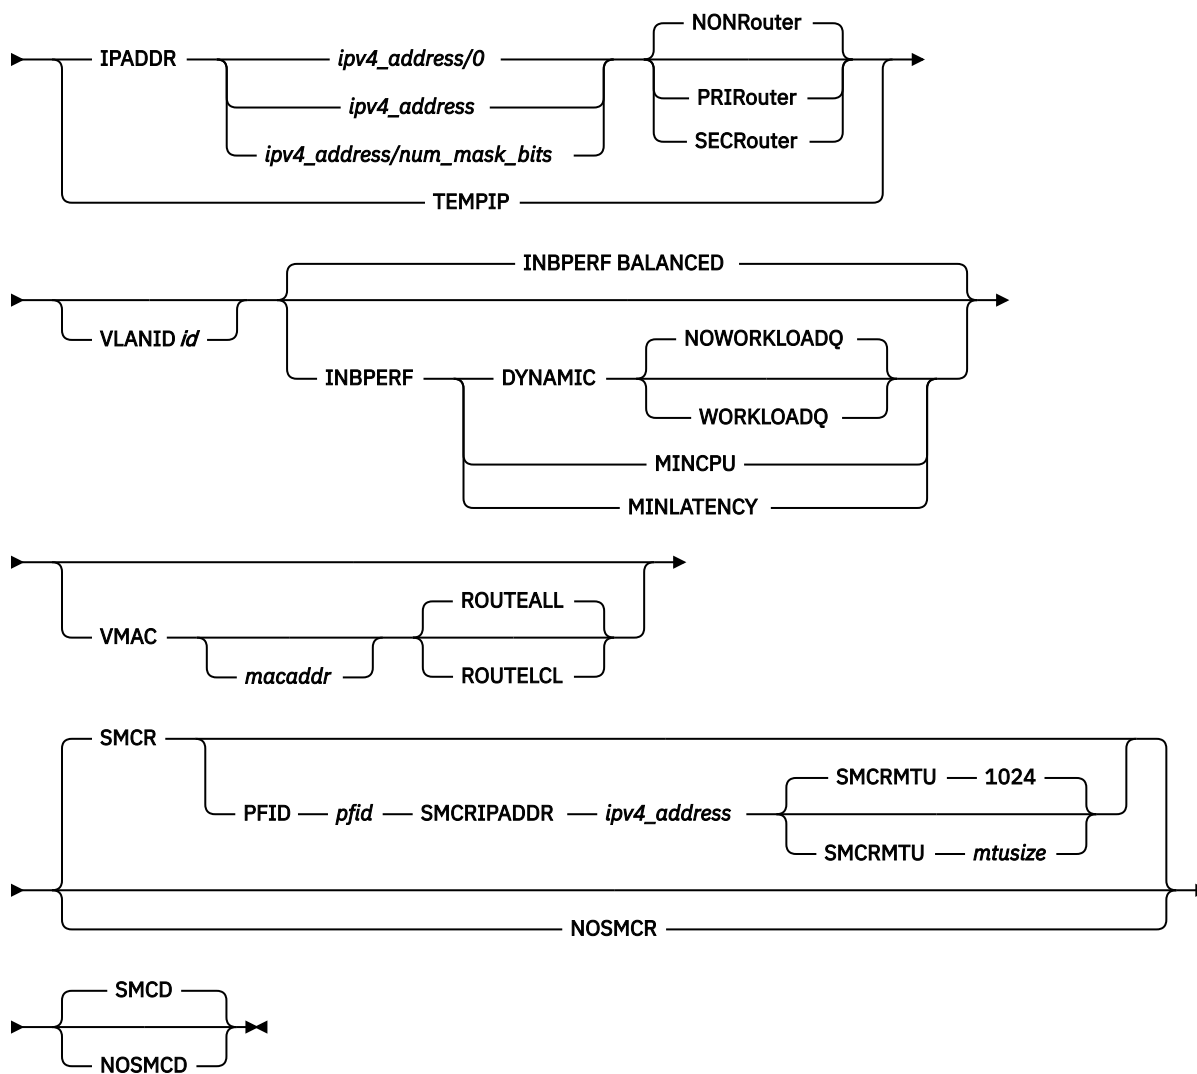

Rule: Specify the required parameters and the CHPIDTYPE parameter in the order shown here. The OSD Interface Definition and OSX Interface Definition parameters can be specified in any order.

►► INTERFace — *intf_name* ►

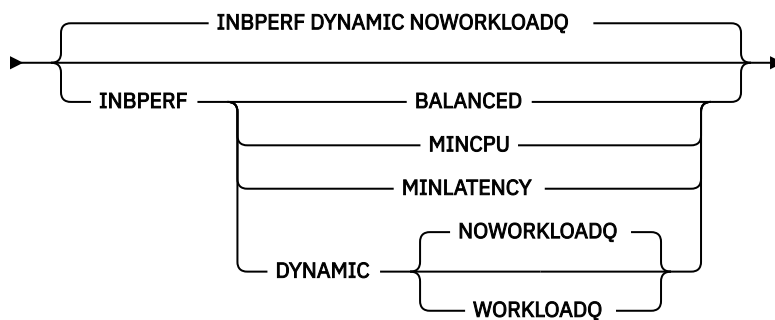

OSD Interface Definition

➤➤ PORTNAME *portname* ➡

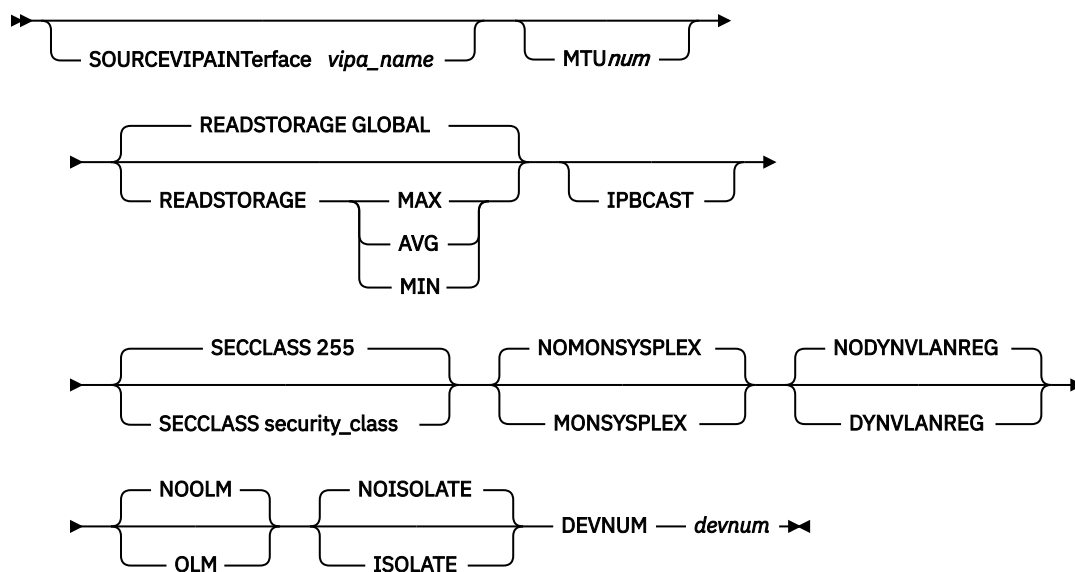

➤➤ DEVNUM — *devnum* ➡

OSX Interface Definition

Common parameters for OSD and OSX interface definitions

Parameters

intf_name

The name of the interface. The maximum length is 16 characters.

Requirement: This name must be different than the name specified for the PORTNAME parameter.

DEFINE

Specifies that this definition is to be added to the list of defined interfaces.

DELETE

Specifies that this definition is to be deleted from the list of defined interfaces. The *intf_name* value must be the name of an interface previously defined by an INTERFACE statement. Specifying INTERFACE DELETE deletes the home IP address for the interface.

IPAQENET

Indicates that the interface uses the interface based on IP assist, which belongs to the QDIO family of interfaces, and uses the Ethernet protocol.

CHPIDTYPE

An optional parameter indicating the CHPID type of the OSA-Express QDIO interface.

OSD

Indicates an external data network type. This is the default value.

OSX

The intraensemble data network. See [z/OS Communications Server: IP Configuration Guide](#) for information about [requirements necessary to make an OSX work](#).

Rule: You must specify an OSD interface definition to make this interface eligible to use Shared Memory Communications over Remote Direct Memory Access (SMC-R) or Shared Memory Communications - Direct Memory Access (SMC-D).

CHPID *chpid*

This parameter applies only to interfaces of CHPIDTYPE OSX and is used to specify the CHPID for the interface. This value is a 2-character hexadecimal value (00 - FF).

PORTNAME *portname*

Use this parameter to specify the PORT name that is in the TRLE definition for the QDIO interface. The TRLE must be defined as MPCLEVEL=QDIO. For details about defining a TRLE, see [z/OS Communications Server: SNA Resource Definition Reference](#).

Requirement: The *portname* value must be different than the name specified for *intf_name*.

IPADDR

ipv4_address

The home IP address for this interface.

Requirement: The IP address must be specified in dotted decimal form.

num_mask_bits

An integer value in the range 0 - 32 that represents the number of leftmost significant bits for the subnet mask of the interface. This value also controls how ARP processing for VIPAs is handled for this interface. When you specify a nonzero value, the TCP/IP stack informs OSA to perform ARP processing for a VIPA only if the VIPA is configured in the same subnet as the OSA (as defined by this subnet mask). The default is 0 for CHPIDTYPE OSD. This parameter is required for CHPIDTYPE OSX..

Requirement: If you are configuring multiple IPv4 VLAN interfaces to the same OSA feature, then you must specify a nonzero value for the *num_mask_bits* variable for each of these interfaces and the resulting subnet must be unique for each of these interfaces.

Rule: If you are using OMROUTE and OMROUTE is not configured to ignore this interface, ensure that the subnet mask value that you define on this parameter matches the subnet mask used by OMROUTE for this interface. The subnet mask used by OMROUTE is the subnet mask value defined on the corresponding OMROUTE statement (OSPF_INTERFACE, RIP_INTERFACE, or INTERFACE) for this interface. If no OMROUTE statement is specified for this interface, the subnet mask used by OMROUTE is the class mask for the interface IP address.

TEMPIP

Specifies that the interface starts with an IP address of 0.0.0.0. The interface can be used for broadcast traffic. This parameter applies only to interfaces that are defined with CHPIDTYPE OSD.

Guideline: Use TEMPIP interfaces in a unit test environment to support an application that provides a DHCP client, such as IBM Rational Developer for System z Unit Test feature (Rdz-UT). For more information about configuring a TEMPIP interface, see [Using TEMPIP interfaces in z/OS Communications Server: IP Configuration Guide](#).

NONROUTER

If a datagram is received at this interface for an unknown IP address, the datagram is not routed to this TCP/IP instance. This is the default value.

The PRIROUTER and SECROUTER parameters interact with the VLANID parameter. See the VLANID parameter definition to understand this relationship.

Rule: This keyword applies only to interfaces of CHPIDTYPE OSD and is ignored if the VMAC parameter is configured on the INTERFACE statement.

PRIROUTER

If a datagram is received at this interface for an unknown IP address and is not destined for a virtual MAC, the datagram is routed to this TCP/IP instance. This parameter interacts with the VLANID parameter. See the VLANID parameter definition to understand this relationship.

Rule: This keyword applies only to interfaces of CHPIDTYPE OSD and is ignored if the VMAC parameter is configured on the INTERFACE statement.

SECROUTER

If a datagram is received at this interface for an unknown IP address and is not destined for a virtual MAC, and there is no active TCP/IP instance defined as PRIROUTER, then the datagram is routed to this TCP/IP instance. This parameter interacts with the VLANID parameter. See the VLANID parameter definition to understand this relationship.

Rule: This keyword applies only to interfaces of CHPIDTYPE OSD and is ignored if the VMAC parameter is configured on the INTERFACE statement.

VLANID id

Specifies the decimal virtual LAN identifier to be assigned to the OSA interface. This field should be a virtual LAN identifier recognized by the switch for the LAN that is connected to this OSA interface. The valid range is 1 - 4094. This parameter is optional for CHPIDTYPE OSD and required for CHPIDTYPE OSX.

Guideline: Installation configuration on other platforms or related to Ensemble networking can limit the maximum VLANID of 4096.

The VLANID parameter interacts with the PRIROUTER and SECROUTER parameters. If you configure both the VLANID parameter and either PRIROUTER or SECROUTER parameter, then this TCP/IP instance acts as a router for this VLAN (ID) only. Datagrams that are received at this device instance for an unknown IP address and are not destined for a virtual MAC are routed only to this TCP/IP instance if it is VLAN tagged with this VLAN ID. For more information about VLANID parameter interactions, see [OSA VLAN in z/OS Communications Server: IP Configuration Guide](#).

Rule: If you are configuring multiple VLAN interfaces to the same OSA feature, then you must specify the VMAC parameter (with the default ROUTEALL attribute) on the INTERFACE statement for each of these interfaces.

Restriction: The stack supports a maximum of 32 IPv4 VLAN interfaces to the same OSA port. Additional VLANID limitations might exist if this interface can be used with Shared Memory Communications over Remote Direct Memory Access (SMC-R). See [VLANID considerations in z/OS Communications Server: IP Configuration Guide](#) for details.

INBPERF

An optional parameter that indicates how processing of inbound traffic for the QDIO interface is performed.

There are three supported static settings that indicate how frequently the adapter should interrupt the host for inbound traffic: BALANCED, MINCPU, and MINLATENCY. The static settings use static interrupt-timing values. The static values are not always optimal for all workload types or traffic patterns, and the static values cannot account for changes in traffic patterns.

There is also one supported dynamic setting (DYNAMIC). This setting causes the host (stack) to dynamically adjust the timer-interrupt value while the device is active and in use. This function exploits an OSA hardware function called Dynamic LAN Idle. Unlike the static settings, the DYNAMIC setting reacts to changes in traffic patterns and sets the interrupt-timing values to maximize throughput. The dynamic setting does not incur additional CPU consumption that might be produced when you specify any of the static settings. In addition, the DYNAMIC setting uses the OSA Dynamic Router Architecture function to enable inbound workload queues for specific inbound traffic types.

Result: When you specify OLM on the INTERFACE statement, the INBPERF parameter is ignored and the statement takes the value DYNAMIC.

Valid values for INBPERF are:

BALANCED

This setting uses a static interrupt-timing value, which is selected to achieve reasonably high throughput and reasonably low CPU consumption. This is the default value for CHPIDTYPE OSD. .

DYNAMIC

This setting causes the host to dynamically signal the OSA feature to change the timer-interrupt value, based on current inbound workload conditions. The DYNAMIC setting is effective only for OSA-Express2 or later features on at least an IBM System z9® that supports the corresponding Dynamic LAN Idle function. See the 2097DEVICE Preventive Service Planning (PSP) bucket for more information about the OSA-Express3 adapter that supports this function. The DYNAMIC setting should outperform the other three static settings for most workload combinations. This is the default value for CHPIDTYPE OSX.

If the DYNAMIC setting is specified for an OSA-Express adapter that does not support the dynamic LAN Idle function, the stack reverts to using the BALANCED setting.

WORKLOADQ | NOWORKLOADQ

This sub parameter controls the inbound workload queuing function for the interface. inbound workload queuing is effective only for OSA-Express features in QDIO mode that support the corresponding Data Router Architecture. OSA-Express features that support workload queuing do not necessarily support workload queuing for all possible traffic types. For more information about the inbound workload queuing function and the OSA-Express features that support it, see [QDIO inbound workload queueing in z/OS Communications Server: IP Configuration Guide](#).

NOWORKLOADQ

Specifies that inbound workload queuing is not enabled for inbound traffic. All inbound traffic for this interface uses a single input queue. This is the default value.

WORKLOADQ

Specifies that inbound workload queuing (IWQ) is enabled for inbound traffic.

If the WORKLOADQ sub parameter is specified, inbound workload queuing is enabled for specific inbound traffic types. A primary input queue is reserved for all other traffic types.

Ancillary input queues (AIQs) are created for the following inbound traffic types when supported by the OSA-Express feature:

- Sysplex distributor
- Streaming workloads (for example FTP)
- Enterprise Extender (EE)
- IP Security (IPSec)
- IBM z/OS Container Extensions (zCX)

Requirement: You must specify the VMAC parameter with WORKLOADQ to enable inbound workload queuing.

Restrictions:

- Bulk-mode TCP connection registration is supported only in configurations in which a single inbound interface is servicing the bulk-mode TCP connection. If a bulk-mode TCP connection detects that it is receiving data over multiple interfaces, Inbound workload queuing is disabled for the TCP connection and inbound data from that point forward is delivered to the primary input queue.
- Inbound workload queuing does not apply for traffic that is sent over an OSA port that is shared by the receiving TCP/IP stack when an indirect route (where the next hop and destination IP address are different) is being used; this traffic is placed on the primary input queue. Inbound workload queuing does apply when traffic on the shared OSA path uses a direct route (where the next hop and destination IP address are the same).

Guideline: The WORKLOADQ parameter requires an additional amount of fixed 4K CSM HVCOMMON storage per AIQ. The amount of storage consumed per AIQ is based on the amount of storage defined for READSTORAGE for this interface. The bulk AIQ is always backed with this additional CSM storage. The remaining AIQs are not backed by the additional CSM storage until the specific function (EE, SD, IPSec, or zCX) is used. The EE AIQ is backed by fixed 4K CSM DSPACE64 storage (instead of HVCOMMON). To verify the amount of CSM storage that is being used for each input queue, display the VTAM TRLE name that is associated with the interface. The WORKLOADQ parameter also requires an additional 36K of ECSA per AIQ.

Tip: The additional CSM storage consumed by each OSA interface using WORKLOADQ consumes fixed (real) storage. It is recommended that you verify that the additional fixed storage required by enabling WORKLOADQ (per OSA interface) will not approach any of the following limits:

- The CSM FIXED MAXIMUM value used by Communications Server (use the D NET, CSM command and see the CSM FIXED MAXIMUM value defined in IVTPRM00)
- The actual real storage available to this z/OS system (see D M=STOR or D M=HIGH)

If the WORKLOADQ setting is specified for an OSA-Express adapter that does not support the Data Router Architecture function, the stack reverts to using a single input queue.

MINCPU

This setting uses a static interrupt-timing value, which is selected to minimize host interrupts without regard to throughput. This mode of operation might result in minor queuing delays (latency) for packets flowing into the host, which is not optimal for workloads with demanding latency requirements.

MINLATENCY

This setting uses a static interrupt-timing value, which is selected to minimize latency (delay), by more aggressively sending received packets to the host. This mode of operation generally results in higher CPU consumption than the other three settings. Use this setting only if host CPU consumption is not an issue.

Tip: The OSA-Express Enhanced Inbound Blocking function is dependent on the INBPERF setting for your interface. For more information about the OSA-Express EIB function and using the VTAM QDIOEIB start option, see the [QDIOEIB start option](#) in *z/OS Communications Server: SNA Resource Definition Reference*.

VMAC *macaddr*

Specifies the virtual MAC address, which can be represented by 12 hexadecimal characters. The OSA device uses this address rather than the physical MAC address of the device for all IPv4 packets sent to and received from this TCP/IP stack. For CHPIDTYPE OSD, using a virtual MAC address is optional. For CHPIDTYPE OSX, using a virtual MAC address is required, so the VMAC parameter is the default

The *macaddr* value is optional. The *macaddr* value is optional for CHPIDTYPE OSD and cannot be specified for CHPIDTYPE OSX. If you do not code the *macaddr* value, then the OSA device generates a virtual MAC address. If you do code the *macaddr* value, it must be defined as a locally administered individual MAC address. This means the MAC address must have bit 6 (the universal or local flag U bit) of the first byte set to 1 and bit 7 (the group or individual flag G bit) of the first byte set to 0. The second hexadecimal character must be 2, 6, A, or E. The bit positions within the 12 hexadecimal characters are indicated as follows:

	1 1	3 3	4
0	5 6	1 2	7
+	+	+	+
xxxxxxUGxxxxxxx	xxxxxxxxxxxxxxxx	xxxxxxxxxxxxxxxx	xxxxxxxxxxxxxxxx
+	+	+	+

Rules:

- The same virtual MAC address generated by the OSA device during interface activation remains in effect for this OSA for this TCP/IP stack, even if the interface is stopped or becomes inoperative

(INOPs). A new virtual MAC address is generated only if the INTERFACE statement is deleted and redefined or if the TCP/IP stack is recycled.

- The NONROUTER, PRIROUTER, and SECROUTER parameters are ignored for an OSA interface if the VMAC parameter is configured on the INTERFACE statement.

Guideline: Unless the virtual MAC address representing this OSA device must remain the same even after TCP/IP termination and restart, configure VMAC without a *macaddr* value and allow the OSA device to generate it. This guarantees that the VMAC address is unique from all other physical MAC addresses and from all other VMAC addresses generated by any OSA feature.

Tip: If DEVNUM is coded on an IPAQENET interface statement and VMAC is not specified, the interface will default to VMAC ROUTEALL when the TCP/IP stack is started on a z17 or higher machine.

ROUTEALL

Specifies that all IP traffic destined to the virtual MAC is forwarded by the OSA device to the TCP/IP stack. This is the default value. See the [router information in z/OS Communications Server: IP Configuration Guide](#) for more details.

ROUTECL

Specifies that only traffic destined to the virtual MAC and whose destination IP address is registered with the OSA device by this TCP/IP stack is forwarded by the OSA. See the [router information in z/OS Communications Server: IP Configuration Guide](#) for more details.

SMCR | NOSMCR

Specifies whether this interface can be used with Shared Memory Communications over Remote Direct Memory Access (SMC-R) for external data network communications.

NOSMCR

Specifies that this interface cannot be used for new TCP connections with SMC-R for external data network communications.

SMCR

Specifies that this interface can be used for new TCP connections with SMC-R for external data network communications. This is the default setting.

Rules:

- SMCR and NOSMCR are valid with CHPIDTYPE OSD definitions only.
- SMCR has no effect unless at least one RoCE Express Peripheral Component Interconnect Express (PCIe) function ID (PFID) value is specified by using the PFID subparameter of the SMCR parameter on this INTERFACE statement or the PFID subparameter of the SMCR parameter on the GLOBALCONFIG statement.
- SMCR has no effect unless a nonzero subnet mask is configured on the INTERFACE statement.

PFID *pfid*

Specifies the Peripheral Component Interconnect® Express (PCIe) function ID (PFID) value for a RoCE Express feature that this interface uses for SMC-Rv2 communications. The RoCE Express feature used here must support RoCEv2 (Routable RoCE) to be used for SMC-Rv2 communication (See the rules below). A *pfid* is a 2-byte hexadecimal value that identifies this TCP/IP stack's representation of a RoCE Express feature. z/OS supports values for *pfid* in the range 0 to FFFF. The maximum supported PFID value depends on the IBM Z machine level.

The PFID configured on the OSA-Express INTERFACE statement is used for SMC-Rv2 communications. When SMC-Rv1 communications are also required, configuring the same PFID on the GLOBALCONFIG statement enables this PFID for SMC-Rv1. However, the VLAN definition for the OSA INTERFACE statement impacts the SMC-Rv1 communications capability as follows:

- When VLAN is configured on the OSA INTERFACE statement (trunk mode), this PFID can also be used for SMC-Rv1 communications. For this case, configuring this same PFID on the GLOBALCONFIG statement enables SMC-Rv1 connectivity.
- When VLAN is not configured on the OSA INTERFACE statement (access mode), this PFID can conditionally be used for SMC-Rv1 connectivity described as follows:

- When the OSA interface and all RoCE PFIDs on the PNET that are to be used for SMC-Rv1 connectivity are all defined in the associated switch ports with a single VLAN ID, SMC-Rv1 connectivity is supported. For this case, the PFID should be configured on the GLOBALCONFIG statement.

Restriction: When the OSA interface and all RoCE PFIDs on the PNET that are to be used for SMC-Rv1 connectivity are not defined in the associated switch ports with a single VLAN ID, SMC-Rv1 connectivity is not supported. When enabling SMC-Rv2 communications in this access mode configuration the PFID must not be configured on the GLOBALCONFIG statement.

Result: Configuring PFID on the GLOBALCONFIG statement for this case could result in connection hangs with SMC-Rv1 link timeouts.

Rules:

- You must code a PFID subparameter for this interface to use SMC-Rv2 communications.
- The PFID value that is coded must represent a RoCE Express2 or later feature to use SMC-Rv2 communications.
- RoCE Express2 or later features operate in a shared RoCE environment. You cannot simultaneously activate a RoCE Express feature that uses the same PFID value from different TCP/IP stacks within the same logical partition (LPAR).
- If the same PFID is coded on both the GLOBALCONFIG statement and the INTERFACE statement, the PFID can be used for SMC-Rv1 as well as SMC-Rv2 communications.
- The same PFID can only be specified on multiple OSA interfaces if they all specify a VLAN ID, or if they all do not specify a VLAN ID and are using different OSA ports on the same IP subnet. For more information about configuring PFID for SMC-Rv2 connections, see [z/OS Communications Server: IP Configuration Guide](#).

SMCRIPADDR IPAddress

The IPv4 address used for SMC-Rv2 communications for this interface. The IP address must be specified in dotted decimal form.

Rules:

- You must code an SMCRIPADDR subparameter for this interface to use SMC-Rv2 communications.
- SMCRIPADDR must be in the same subnet that is specified on the IPADDR parameter of the OSA-Express QDIO INTERFACE statement.
- The same IP address can be specified for SMCRIPADDR on multiple interfaces only if they all use the same PFID, and if they all specify the same VLAN ID, or if they all do not specify a VLAN ID and are in the same subnet. For more information about configuring SMCRIPADDR for SMC-Rv2 connections, see [z/OS Communications Server: IP Configuration Guide](#).

SMCRMTU mtusize

Specifies the maximum transmission unit (MTU) value to be used for SMC-Rv2 communications for this interface. The MTU value can be 1024, 2048, or 4096. The default value is 1024 and can be used for most workloads. If you set the MTU size to 2048 or 4096, you must also enable jumbo frames on all switches in the network path for all peer hosts. For more information about the RoCE maximum transmission unit, see [z/OS Communications Server: IP Configuration Guide](#).

Rules:

- A SMC-Rv2 PFID will only use one MTU value. If the same SMC-Rv2 PFID is defined on two different OSA-Express QDIO INTERFACE statements, their respective SMCRMTU values should match. If two different SMCRMTU values are coded for the same SMC-Rv2 PFID, the first OSA-Express QDIO INTERFACE that is started will have its SMCRMTU value used.
- SMC-Rv1 communications will use the PFID MTU value defined on the GLOBALCONFIG SMCR statement.

Guideline: If you enable Multipath and equal-cost interfaces are associated with different IP subnets, enabling SMC for some of, but not all, the interfaces can cause unpredictable SMC usage. You must specify either SMCD or NOSMCD on all equal-cost interfaces.

SMCD | NOSMCD

Specifies whether this interface can be used with Shared Memory Communications - Direct Memory Access (SMC-D).

NOSMCD

Specifies that this interface cannot be used for new TCP connections with SMC-D.

SMCD

Specifies that this interface can be used for new TCP connections with SMC-D. This is the default setting.

Rules:

- SMCD and NOSMCD are valid with CHPIDTYPE OSD definitions only.
- SMCD has no effect unless a nonzero subnet mask is configured on the INTERFACE statement.

Guideline: If you enable Multipath and equal-cost interfaces are associated with different IP subnets, enabling SMC for some of, but not all, the interfaces can cause unpredictable SMC usage. You must specify either SMCD or NOSMCD on all equal-cost interfaces.

DEVNUM *devnum*

This parameter applies to interfaces with CHPIDTYPE OSD specified and is only used for migration purposes. It is used to specify the device number that identifies the associated OSH CHPID of an Network Express feature. The first available device associated with the OSH CHPID is used for this interface. This value is a 4-character hexadecimal value (0000 - FFFF).

When specified, this parameter is used to conditionally migrate the QDIO (IPAQENET) interface definition associated with an OSA-Express feature to an Enhanced QDIO (EQENET) interface definition associated with an Network Express feature. If the TCP/IP stack is started on a System z16 or earlier machine, the DEVNUM keyword is ignored and activation of the IPAQENET interface proceeds normally. If the TCP/IP stack is started on a z17 or higher machine, the DEVNUM keyword automatically converts your IPAQENET interface definition to an EQENET interface definition. For more information about migration scenarios, refer to the IP Configuration Guide.

Tips:

1. The device selected might not be the same as the device number specified. Netstat DEvlinks/-d displays the actual device number used.
2. Verify that your HCD I/O configuration specifies a sufficient number of OSH devices to support all of your defined interfaces associated with all the active stacks in this z/OS instance.
 - You must code a sufficient number of devices to accommodate the number of concurrent instances that will use an Network Express port. For each EQENET or IPAQENET or EQENET6 or IPAQENET6 statement in your TCP/IP configurations that specifies DEVNUM for the same OSH CHPID, you must configure a device in the HCD. For example, within one TCP/IP stack profile, if you have three interface statements with DEVNUMs for the same OSH CHPID, then you will need three devices in the HCD for that OSHCHPID.
 - If you have multiple interface statements with DEVNUMs for the same shared OSA port, you must specify the same DEVNUM value on all the interface statements that are using the same shared OSA port. An available device associated with that port will be assigned to each interface.
3. When the DEVNUM parameter is specified on the IPAQENET interface, subnet mask bits must be coded on the IPADDR parameter.
4. If DEVNUM is coded on an IPAQENET interface statement and VMAC is not specified, the interface will default to VMAC ROUTEALL when the TCP/IP stack is started on a z17 or higher machine.

5. If DEVNUM is coded on the IPAQENET INTERFACE statement and the interface is auto-migrated to EQENET, the IWQ function is automatically enabled. IWQ requires additional storage. If this IPAQENET INTERFACE statement did not specify INBPERF DYNAMIC WORKLOADQ (IWQ) then you will see a storage increase. For additional information, refer to the Guideline and Tip described under the INBPERF DYNAMIC WORKLOADQ parameter.

SOURCEVIPAINTERFACE *vipa_name*

Specifies which previously-defined static VIPA interface is used for SOURCEVIPA (when IPCONFIG SOURCEVIPA is in effect). The *vipa_name* value is the interface name (or link name) for a VIRTUAL interface. This parameter is optional.

Requirement: The VIRTUAL interface must be defined prior to specifying this INTERFACE statement to the TCP/IP stack. It must either already be defined, or the INTERFACE statement (or DEVICE and LINK statements) that define the static VIPA must precede this INTERFACE statement in the profile data set.

Tip: The SOURCEVIPAINTERFACE setting can be overridden. See the information about [source IP selection](#) in [z/OS Communications Server: IP Configuration Guide](#) for the hierarchy of ways that the source IP address of an outbound packet is determined.

MTU *num*

The maximum transmission unit (MTU), in bytes. This value can be in the range 576 - 8992. The minimum MTU for IPv4 is 576. The stack takes the minimum of the configured value and the value supported by the device (returned by OSA).

The MTU default, which depends on the value that is supported by the device, is the following value:

- Gigabit Ethernet default MTU = 8992
- Fast Ethernet default MTU = 1492

The MTU default is 1492 for Fast Ethernet; otherwise, it is 8992.

Rule: If you are using OMROUTE and OMROUTE is not configured to ignore this interface, ensure that the MTU that you define on this parameter matches the MTU used by OMROUTE for this interface. The MTU used by OMROUTE is the MTU value defined on the corresponding OMROUTE statement (OSPF_INTERFACE, RIP_INTERFACE, or INTERFACE) for this interface. If an MTU value is not defined on the corresponding OMROUTE statement for this interface or if no OMROUTE statement is specified for this interface, the MTU used by OMROUTE is the minimum MTU for IPv4 (576).

Tip: See [z/OS Communications Server: IP Configuration Guide](#), in section Maximum transmission unit considerations, for additional information about how TCP/IP uses the MTU to determine the largest size frame to send.

READSTORAGE

An optional parameter indicating the amount of fixed storage that z/OS Communications Server should keep available for read processing for each input queue for this interface. Multiple input queues are used when WORKLOADQ is enabled. See description of the WORKLOADQ parameter for more details.

Use the QDIOSTG VTAM start option to specify a value that applies to all OSA adapters in QDIO mode. You can use the READSTORAGE keyword to override the global QDIOSTG value for this adapter based on the inbound workload that you expect over this interface on this stack. The valid values for READSTORAGE are:

GLOBAL

The amount of storage is determined by the QDIOSTG VTAM start option. This is the default value.

MAX

Use this value if you expect a heavy inbound workload over this interface.

AVG

Use this value if you expect a medium inbound workload over this interface.

MIN

Use this value if you expect a light inbound workload over this interface.

Tip:

- The amount of storage which corresponds to each of these values is different for an OSA with at least 25 GbE of bandwidth than for an OSA with less than 25 GbE of bandwidth. See [QDIOSTG start option in z/OS Communications Server: SNA Resource Definition Reference](#) for details about exactly how much storage is allocated by z/OS Communications Server for each of these values.
- The VTAM QDIOSTG start option or the READSTORAGE parameter, which overrides QDIOSTG, must be set to 126 (8 M) in order to support the OSA-Express Enhanced Inbound Blocking (EIB) function. For more information about the OSA-Express EIB function and using the VTAM QDIOEIB start option, see the [QDIOEIB start option in z/OS Communications Server: SNA Resource Definition Reference](#).
- For a list of all related OSA Express Best Practices for optimizing your performance for your OSA interface configuration, see [IBM z/OS Communications Server and OSA Express Best Practices](#).

IPBCAST

Specifies that the interface both sends and receives IP broadcast packets. If this parameter is not specified, no IP broadcast packets are sent or received on this interface.

SECCLASS *security_class*

Use this parameter to associate a security class for IP filtering with this interface. For traffic over the interface to match a filter rule, the filter rule must have the same security class value as the interface or a value of 0. You can specify filter rules in the TCP/IP profile or in an IP security policy file that is read by the Policy Agent. Filter rules can include a security class specification on the IpService statement in an IP Security policy file or on the SECCLASS parameter on the IPSECRULE statement in the TCP/IP profile.

Valid security classes are identified as a number in the range 1 - 255. The default value is 255.

For more information about security class values, see [z/OS Communications Server: IP Configuration Guide](#).

The TCP/IP stack ignores this value if IPSECURITY is not specified on the IPCONFIG statement.

MONSYSPLEX | NOMONSYSPLEX

Specifies whether sysplex autonomics should monitor the interface's status.

NOMONSYSPLEX

Specifies that sysplex autonomics should not monitor the interface's status. This is the default value.

MONSYSPLEX

Specifies that sysplex autonomics should monitor the interface's status.

Restriction: The MONSYSPLEX attribute is not in effect unless the MONINTERFACE keyword is specified on the GLOBALCONFIG SYSPLEXMONITOR profile statement. The presence of dynamic routes over this interface is monitored if the DYNROUTE keyword is also specified on the GLOBALCONFIG SYSPLEXMONITOR profile statement.

DYNVLANREG | NODYNVLANREG

This parameter controls whether or not the VLAN ID for this interface is dynamically or statically registered with the physical switch on the LAN.

Restriction: This parameter is applicable only if a VLAN ID is specified on the statement.

Dynamic registration of VLAN IDs is handled by the OSA feature and the physical switch on your LAN. Therefore, in order for the DYNVLANREG parameter to be effective, both must be at a level that provides the necessary hardware support for dynamic VLAN ID registration. After the interface is active, you can view the Netstat DEvlinks/-d report output to determine whether your OSA feature can support VLAN dynamic registration. This Netstat report also displays whether dynamic VLAN ID registration has been configured for the interface.

NODYNVLANREG

Specifies that if a VLAN ID is configured for this interface, it must be manually registered with the physical switches on the corresponding LAN. This is the default value. If this parameter is specified without a VLAN ID, then it is ignored.

DYNVLANREG

Specifies that if a VLAN ID is configured for this interface, it is dynamically registered with the physical switches on the corresponding LAN. If this parameter is specified without a VLAN ID, then warning message EZZ0056I is issued and the NODYNVLANREG setting is used instead.

OLM | NOOLM

An optional parameter indicating whether an OSA-Express adapter operates in optimized latency mode.

NOOLM

Specifies that the OSA-Express adapter should not operate in optimized latency mode. This is the default value.

OLM

Specifies that the OSA-Express adapter operates in optimized latency mode (OLM). Optimized latency mode optimizes interrupt processing for both inbound and outbound data. Use this mode for workloads that have demanding latency requirements. Because this mode can provide significant increases of throughput, particularly for interactive, non-streaming workloads. For more information about optimized latency mode, see [Optimized latency mode in z/OS Communications Server: IP Configuration Guide](#).

Guidelines:

- Because of the operating characteristics of optimized latency mode, you might need to change your configuration to direct traffic to particular OSA-Express write priority queues and to limit the number of concurrent users sharing an OSA-Express configured for optimized latency mode. For more information about OLM, see [Optimized latency mode in z/OS Communications Server: IP Configuration Guide](#).
- The optimized latency mode function targets a z/OS environment with a high-volume, interactive workloads. Although optimized latency mode can compensate for some mixing of workloads, an excessive amount of high-volume streaming workloads, such as bulk data or file transfer, can result in higher CPU consumption.

Restrictions:

- This function is limited to OSA-Express3 or later Ethernet features in QDIO mode that are running with an IBM z10 or later. See the 2097 DEVICE Preventive Service Planning (PSP) bucket for more information.
- Traffic that is either inbound over or being forwarded to an OSA-Express configured to use optimized latency mode is not eligible for the accelerated routing function provided by HiperSockets Accelerator and QDIO Accelerator.
- For an OSA-Express configured to use optimized latency mode, the stack ignores the configured or default INBPERF setting and uses the value DYNAMIC.

ISOLATE | NOISOLATE

Specifies whether packets should be directly routed between TCP/IP stacks that share the OSA adapter.

NOISOLATE

Route packets directly between TCP/IP stacks sharing the OSA adapter. In this mode, if the next hop address was registered by another stack that is sharing the OSA adapter, then the OSA-Express adapter routes the packet directly to the sharing stack without putting the packet on the external LAN.

ISOLATE

Prevent OSA-Express from routing packets directly to another TCP/IP stack that is sharing the OSA adapter. In this mode, OSA-Express adapter discards any packets when the next hop address was registered by another stack that is sharing the OSA adapter. Packets can flow between two

stacks that share the OSA only by first going through a router on the LAN. For more details, see the OSA-Express connection isolation information in [z/OS Communications Server: IP Configuration Guide](#).

Tips:

- If you isolate an interface, there might be an adverse effect on latency.
- You can selectively apply OSA connection isolation to individual virtual LANs.
- The OSA adapter requires that both stacks sharing the port be non-isolated for direct routing to occur. Therefore, for traffic between two stacks sharing the OSA adapter, as long as at least one of the stacks is isolated, connection isolation is in effect for traffic in both directions between these stacks.

Restriction: This function is limited to OSA-Express2 or later Ethernet features in QDIO mode and running at least an IBM System z9 Enterprise Class (EC) or z9 Business Class (BC). See the 2094DEVICE, 2096DEVICE, 2097DEVICE, or 2098DEVICE Preventive Service Planning (PSP) bucket for more information.

Steps for modifying

See [“Summary of INTERFACE statements” on page 80](#) for modification information.

Examples

```
INTERFACE OSAQDIO24
DEFINE IPAQENET
PORTNAME OSAQDIO2
SOURCEVIPAIN VIPAV4
IPADDR 100.1.1.1/24
```

- [“STOP statement” on page 243](#)

INTERFACE - EQENET Network Express Enhanced QDIO interfaces statement

Use the INTERFACE statement to specify an Network Express Enhanced QDIO Ethernet interface for IPv4.

Restriction: This statement applies to IPv4 IP addresses only.

To determine the Network Express microcode level, use the Netstat DEvlinks/-d report output. If a specific Network Express function is documented with a minimum microcode level, you can use this command to determine whether that function is supported. IBM service might request the microcode level for problem diagnosis. For more information, see [Netstat DEvlinks/-d report](#) in *z/OS Communications Server: IP System Administrator's Commands*.

When you start an EQENET interface (and you did not specify VMAC with ROUTEALL), TCP/IP registers all non-loopback local (home) IPv4 addresses for this TCP/IP instance to the Network Express feature. If you subsequently add, delete, or change any home IPv4 addresses on this TCP/IP instance, TCP/IP dynamically registers the changes to the Network Express feature. The OSA adapter routes datagrams destined for those IPv4 addresses to this TCP/IP instance.

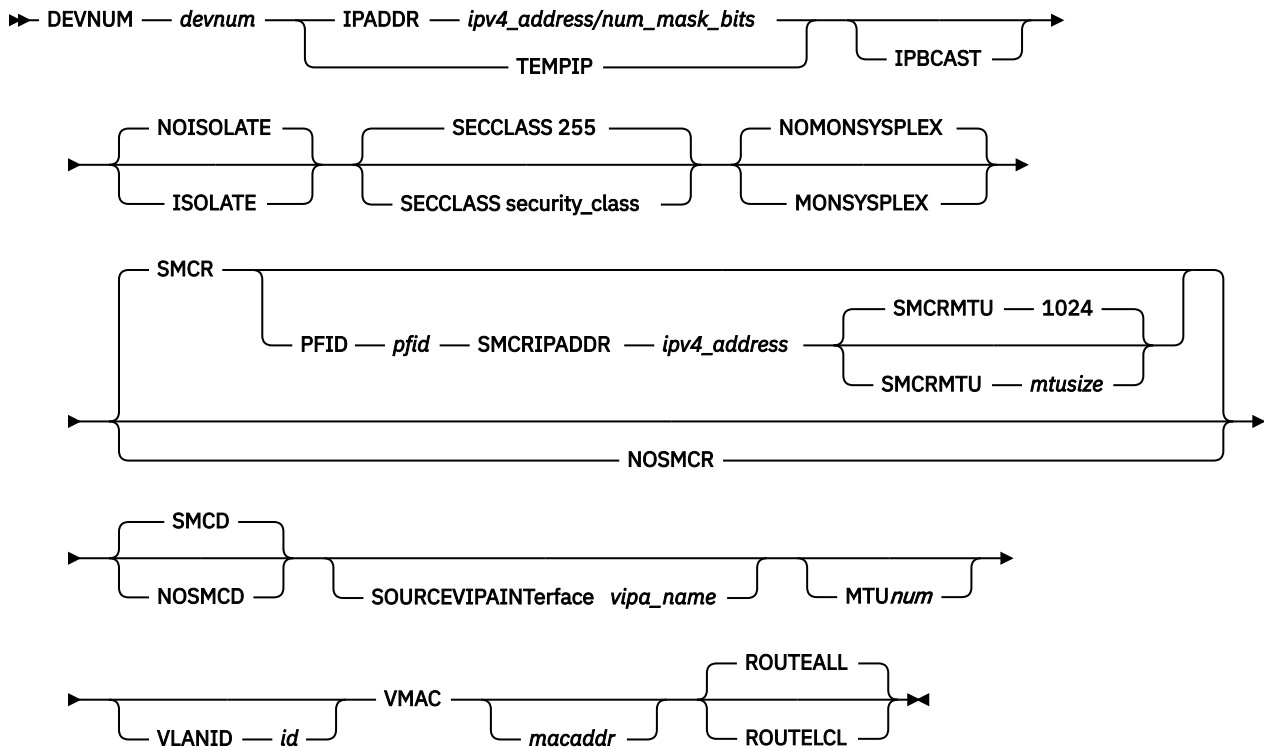

If a datagram is received at the OSA adapter for an unregistered IPv4 address, then the Network Express feature routes the datagram to the TCP/IP instance, depending on the setting of ROUTEALL or ROUTELCL on the virtual MAC (VMAC) address. If a datagram is received for this MAC address and the destination IP address has not been registered, then when using ROUTELCL, the datagram is discarded. When using ROUTEALL, the datagram will be processed. Typically, ROUTEALL is used when datagram forwarding is enabled for the stack.

Syntax

Rule: Specify the required parameters in the order shown here. The other parameters can be specified in any order.

Other parameters

Parameters

intf_name

The name of the interface. The maximum length is 16 characters.

DEFINE

Specifies that this definition is to be added to the list of defined interfaces.

DELETE

Specifies that this definition is to be deleted from the list of defined interfaces. The *intf_name* value must be the name of an interface previously defined by an INTERFACE statement. Specifying INTERFACE DELETE deletes the home IP address for the interface.

EQENET

Indicates that the interface uses IP assist, which belongs to the Enhanced QDIO family of interfaces, and uses the Ethernet protocol.

DEVNUM *devnum*

This parameter is used to specify the device number that identifies the associated OSH CHPID of an Network Express feature. The first available device associated with the CHPID is used for this interface. This value is a 4-character hexadecimal value (0000 - FFFF).

Tip:

1. The device selected might not be the same as the device number specified. Netstat DEvlinks/-d displays the actual device number used.
2. Verify that your HCD I/O configuration specifies a sufficient number of OSH devices to support all of your defined interfaces associated with all the active stacks in this z/OS instance.
 - You must code a sufficient number of devices to accommodate the number of concurrent instances that will use an Network Express port. For each EQENET or IPAQENET or EQENET6 or IPAQENET6 statement in your TCP/IP configurations that specifies DEVNUM for the same OSH CHPID, you must configure a device in the HCD. For example, within one TCP/IP stack profile, if you have three interface statements with DEVNUM specified for the same OSH CHPID, then you will need three devices in the HCD for that OSH CHPID.

IPADDR***ipv4_address***

The home IP address for this interface.

Requirement: The IP address must be specified in dotted decimal form.

num_mask_bits

An integer value in the range 0 - 32 that represents the number of leftmost significant bits for the subnet mask of the interface. EQENET requires a nonzero value. The value also controls how ARP processing for VIPAs is handled for this interface. The TCP/IP stack informs OSA to perform ARP processing for a VIPA only if the VIPA is configured in the same subnet as the OSA (as defined by this subnet mask).

Requirement: If you are configuring multiple IPv4 VLAN interfaces to the same Network Express feature, then you must specify a unique nonzero value for the *num_mask_bits* variable for each of these interfaces.

Rule: If you are using OMROUTE and OMROUTE is not configured to ignore this interface, ensure that the subnet mask value that you define on this parameter matches the subnet mask used by OMROUTE for this interface. The subnet mask used by OMROUTE is the subnet mask value defined on the corresponding OMROUTE statement (OSPF_INTERFACE, RIP_INTERFACE, or INTERFACE) for this interface. If no OMROUTE statement is specified for this interface, the subnet mask used by OMROUTE is the class mask for the interface IP address.

IPBCAST

Specifies that the interface both sends and receives IP broadcast packets. If this parameter is not specified, no IP broadcast packets are sent or received on this interface.

ISOLATE | NOISOLATE

Specifies whether packets should be directly routed between TCP/IP stacks that share the OSA adapter.

NOISOLATE

Route packets directly between TCP/IP stacks sharing the OSA adapter. In this mode, if the next hop address was registered by another stack that is sharing the OSA adapter, then the Network Express adapter routes the packet directly to the sharing stack without putting the packet on the external LAN. This is the default value.

ISOLATE

Prevent Network Express from routing packets directly to another TCP/IP stack that is sharing the OSA adapter. In this mode, Network Express adapter discards any packets when the next hop address was registered by another stack that is sharing the OSA adapter. Packets can flow between two stacks that share the OSA only by first going through a router on the LAN. For

more details, see the Network Express connection isolation information in [z/OS Communications Server: IP Configuration Guide](#).

Tip:

- If you isolate an interface, there might be an adverse effect on latency.
- You can selectively apply Network Express connection isolation to individual virtual LANs.
- The Network Express adapter requires that both stacks sharing the port be non-isolated for direct routing to occur. Therefore, for traffic between two stacks sharing the OSA adapter, as long as at least one of the stacks is isolated, connection isolation is in effect for traffic in both directions between these stacks.

MONSYSPLEX | NOMONSYSPLEX

Specifies whether sysplex autonomics should monitor the interface's status.

NOMONSYSPLEX

Specifies that sysplex autonomics should not monitor the interface's status. This is the default value.

MONSYSPLEX

Specifies that sysplex autonomics should monitor the interface's status.

Restriction: The MONSYSPLEX attribute is not in effect unless the MONINTERFACE keyword is specified on the GLOBALCONFIG SYSPLEXMONITOR profile statement. The presence of dynamic routes over this interface is monitored if the DYNROUTE keyword is also specified on the GLOBALCONFIG SYSPLEXMONITOR profile statement.

MTU num

The maximum transmission unit (MTU), in bytes. This value can be in the range 576 - 9000. The minimum MTU for IPv4 is 576. The stack takes the minimum of the configured value and the value supported by the device (returned by OSA).

The MTU default, which depends on the value that is supported by the device, is 9000.

Rule: If you are using OMPROUTE and OMPROUTE is not configured to ignore this interface, ensure that the MTU that you define on this parameter matches the MTU used by OMPROUTE for this interface. The MTU used by OMPROUTE is the MTU value defined on the corresponding OMPROUTE statement (OSPF_INTERFACE, RIP_INTERFACE, or INTERFACE) for this interface. If an MTU value is not defined on the corresponding OMPROUTE statement for this interface or if no OMPROUTE statement is specified for this interface, the MTU used by OMPROUTE is the minimum MTU for IPv4 (576).

Tip: See [z/OS Communications Server: IP Configuration Guide](#), in section Maximum transmission unit considerations, for additional information about how TCP/IP uses the MTU to determine the largest size frame to send.

SECCLASS security_class

Use this parameter to associate a security class for IP filtering with this interface. For traffic over the interface to match a filter rule, the filter rule must have the same security class value as the interface or a value of 0. You can specify filter rules in the TCP/IP profile or in an IP security policy file that is read by the Policy Agent. Filter rules can include a security class specification on the IpService statement in an IP Security policy file or on the SECCLASS parameter on the IPSECRULE statement in the TCP/IP profile.

Valid security classes are identified as a number in the range 1 - 255. The default value is 255. For more information about security class values, see [z/OS Communications Server: IP Configuration Guide](#).

The TCP/IP stack ignores this value if IPSECURITY is not specified on the IPCONFIG statement.

SMCD | NOSMCD

Specifies whether this interface can be used with Shared Memory Communications - Direct Memory Access (SMC-D).

NOSMCD

Specifies that this interface cannot be used for new TCP connections with SMC-D.

SMCD

Specifies that this interface can be used for new TCP connections with SMC-D. This is the default setting.

Rules: SMCD has no effect unless a nonzero subnet mask is configured on the INTERFACE statement.

Guideline: If you enable Multipath and equal-cost interfaces are associated with different IP subnets, enabling SMC for some of, but not all, the interfaces can cause unpredictable SMC usage. You must specify either SMCD or NOSMCD on all equal-cost interfaces.

SMCR | NOSMCR

Specifies whether this interface can be used with Shared Memory Communications over Remote Direct Memory Access (SMC-R) for external data network communications.

NOSMCR

Specifies that this interface cannot be used for new TCP connections with SMC-R for external data network communications.

SMCR

Specifies that this interface can be used for new TCP connections with SMC-R for external data network communications. This is the default setting.

Rule: SMCR has no effect unless at least one Network Express Peripheral Component Interconnect Express (PCIe) function ID (PFID) value is specified by using the PFID subparameter of the SMCR parameter on this INTERFACE statement or the PFID subparameter of the SMCR parameter on the GLOBALCONFIG statement.

PFID *pfid*

Specifies the Peripheral Component Interconnect Express (PCIe) function ID (PFID) value for a Network Express feature that this interface uses for SMC-Rv2 communications. The Network Express feature configured here must specify a PFID whose PCHID (NETH CHPID type) matches the PCHID (OSH CHPID type) value of the DEVNUM associated with the EQENET OSA interface. A *pfid* is a 2-byte hexadecimal value that identifies this TCP/IP stack's representation of a Network Express feature. z/OS supports values for *pfid* in the range 0 to FFFF. The maximum supported PFID value depends on the Z machine level.

Restriction:

- z/OS Communications Server requires the RNIC (PFID value) configured on the Network Express OSA interface SMCR statement for SMC-Rv2 communications be associated with the same physical port (PCHID) as the one used by the OSA NIC for standard ethernet communications. The NETH PCHID of the PFID value must match the OSH PCHID of the DEVNUM or the RNIC will fail during activation.
- SMC-Rv2 communications requires PNetIDs be configured in HCD for both your OSH and NETH PCHIDS.

Rules:

- You must code a PFID subparameter for this interface to use SMC-Rv2 communications.
- The PFID value that is coded must represent a Network Express or later feature to use SMC-Rv2 communications.
- Network Express or later features operate in a shared RoCE environment. You cannot simultaneously activate a RoCE Express feature that uses the same PFID value from different TCP/IP stacks within the same logical partition (LPAR).
- If the same PFID is coded on both the GLOBALCONFIG statement and the INTERFACE statement, the PFID can be used for SMC-Rv1 as well as SMC-Rv2 communications.
- The same PFID can only be specified on multiple OSA interfaces if they all specify a VLAN ID, or if they all do not specify a VLAN ID and are using different OSA ports on the same

IP subnet. For more information about configuring PFID for SMC-Rv2 connections, see [z/OS Communications Server: IP Configuration Guide](#).

SMCRIPADDR *IPAddress*

The IPv4 address used for SMC-Rv2 communications for this interface. The IP address must be specified in dotted decimal form.

Rules:

- You must code an SMCRIPADDR subparameter for this interface to use SMC-Rv2 communications.
- SMCRIPADDR must be in the same subnet that is specified on the IPADDR parameter of the Network Express Enhanced QDIO INTERFACE statement.
- The same IP address can be specified for SMCRIPADDR on multiple interfaces only if they all use the same PFID, and if they all specify the same VLAN ID, or if they all do not specify a VLAN ID and are in the same subnet. For more information about configuring SMCRIPADDR for SMC-Rv2 connections, see [z/OS Communications Server: IP Configuration Guide](#).

SMCRMTU *mtusize*

Specifies the maximum transmission unit (MTU) value to be used for SMC-Rv2 communications for this interface. The MTU value can be 1024, 2048, or 4096. The default value is 1024 and can be used for most workloads. If you set the MTU size to 2048 or 4096, you must also enable jumbo frames on all switches in the network path for all peer hosts. For more information about the RoCE maximum transmission unit, see [z/OS Communications Server: IP Configuration Guide](#).

Rules:

- A SMC-Rv2 PFID will only use one MTU value. If the same SMC-Rv2 PFID is defined on two different OSA-Express QDIO INTERFACE statements, their respective SMCRMTU values should match. If two different SMCRMTU values are coded for the same SMC-Rv2 PFID, the first Network Express Enhanced QDIO INTERFACE that is started will have its SMCRMTU value used.
- SMC-Rv1 communications will use the PFID MTU value defined on the GLOBALCONFIG SMCR statement.

Guideline: If you enable Multipath and equal-cost interfaces are associated with different IP subnets, enabling SMC for some of, but not all, the interfaces can cause unpredictable SMC usage. You must specify either SMCR or NOSMCR on all equal-cost interfaces.

SOURCEVIPAINTERFACE *vipa_name*

Specifies which previously-defined static VIPA interface is used for SOURCEVIPA (when IPCONFIG SOURCEVIPA is in effect). The *vipa_name* value is the interface name (or link name) for a VIRTUAL interface. This parameter is optional.

Requirement: The VIRTUAL interface must be defined prior to specifying this INTERFACE statement to the TCP/IP stack. It must either already be defined, or the INTERFACE statement (or DEVICE and LINK statements) that define the static VIPA must precede this INTERFACE statement in the profile data set.

Tip: The SOURCEVIPAINTERFACE setting can be overridden. See the information about [source IP selection](#) in [z/OS Communications Server: IP Configuration Guide](#) for the hierarchy of ways that the source IP address of an outbound packet is determined.

TEMPIP

Specifies that the interface starts with an IP address of 0.0.0.0. The interface can be used for broadcast traffic.

Guideline: Use TEMPIP interfaces in a unit test environment to support an application that provides a DHCP client, such as IBM Rational Developer for System z Unit Test feature (Rdz-UT). For more information about configuring a TEMPIP interface, see [Using TEMPIP interfaces](#) in [z/OS Communications Server: IP Configuration Guide](#).

Guideline: Installation configuration on other platforms or related to Ensemble networking can limit the maximum VLANID of 4096.

Rule: If you are configuring multiple VLAN interfaces to the same Network Express feature, then you must specify the VMAC parameter (with the default ROUTEALL attribute) on the INTERFACE statement for each of these interfaces.

AC macaddr

The *macaddr* value is optional. If you do not code the *macaddr* value, then the Network Express device generates a virtual MAC address. If you do code the *macaddr* value, it must be defined as a locally administered individual MAC address. This means the MAC address must have bit 6 (the universal or local flag U bit) of the first byte set to 1 and bit 7 (the group or individual flag G bit) of the first byte set to 0. The second hexadecimal character must be 2, 6, A, or E. The bit positions within the 12 hexadecimal characters are indicated as follows :

1	1	3	3	4
0	5	1	2	7
+-----+-----+-----+				
xxxxxxUGxxxxxxxx xxxxxxxxxxxxxxxx xxxxxxxxxxxxxxxx				
+-----+-----+-----+				

Guideline: Unless the virtual MAC address representing this Network Express device must remain the same even after TCP/IP termination and restart, configure VMAC without a macaddr value and allow the Network Express device to generate it. This guarantees that the VMAC address is unique from all other physical MAC addresses and from all other VMAC addresses generated by any Network Express feature.

Specifies that all IP traffic destined to the virtual MAC is forwarded by the Network Express device to the TCP/IP stack. This is the default value. See the [router information](#) in *z/OS Communications Server: IP Configuration Guide* for more details.

Specifies that only traffic destined to the virtual MAC and whose destination IP address is registered with the Network Express device by this TCP/IP stack is forwarded by the Network Express. See the [router information](#) in [z/OS Communications Server: IP Configuration Guide](#) for more details.

Steps for modifying

See [“Summary of INTERFACE statements” on page 80](#) for modification information.

Examples

```
INTERFACE OSA2BP1
DEFINE EQENET
DEVNUM 0172
SOURCEVIPAINIT VIPAV4
IPADDR 100.1.1.1/24
VMAC
```

- [“STOP statement” on page 243](#)

INTERFACE - IPAQIDIO HiperSockets interfaces statement

Use the INTERFACE statement for IPAQIDIO to configure IPv4 HiperSockets connectivity. Use the CHPID parameter to specify the value of the desired IQD CHPID that was configured within HCD. HiperSockets interfaces do not require a corresponding TRLE definition. Instead, the TRLE is dynamically built when the interface is started.

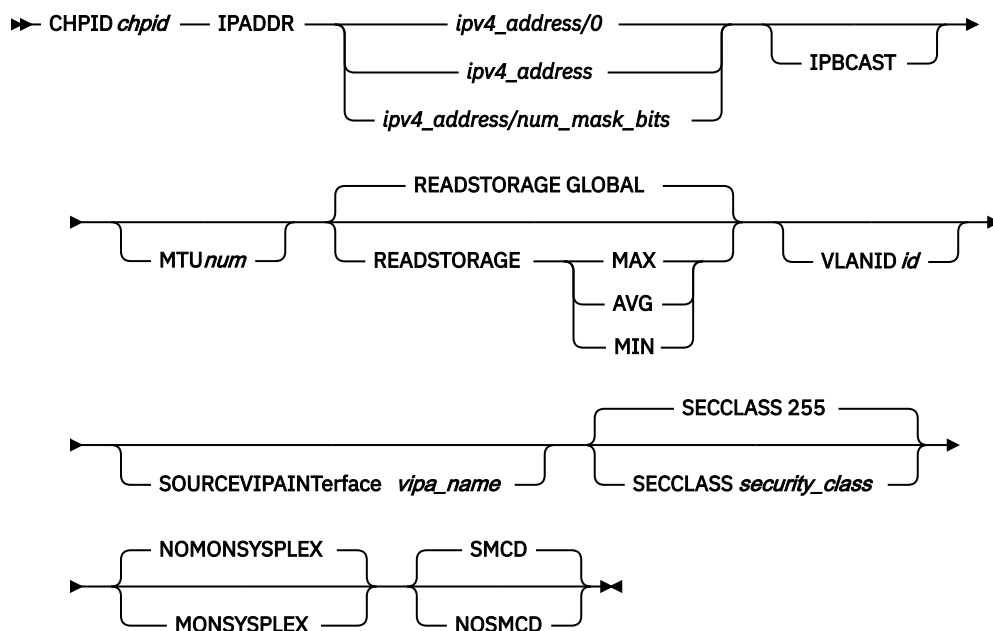

To determine the HiperSockets microcode level, use the DISPLAY TRL command. If a specific HiperSockets function is documented with a minimum microcode level, you can use this command to determine whether that function is supported. IBM service might request the microcode level for problem diagnosis. For more information, see [DISPLAY TRL command](#) in [z/OS Communications Server: SNA Operation](#).

Rule: Specify the required parameters in the order shown here. The Interface Definition parameters can be specified in any order.

Syntax

►► INTERFace — *intf_name* — DEFINE — IPAQIDIO — Interface Definition — DELEte

Interface Definition

Parameters

intf_name

The name of the interface. The maximum length is 16 characters.

DEFINE

Specifies that this definition is to be added to the list of defined interfaces.

DELETE

Specifies that this definition is to be deleted from the list of defined interfaces. The *intf_name* must be the name of an interface that was previously defined by an INTERFACE statement. INTERFACE DELETE deletes the home IP address for the interface.

IPAQIDIO

Indicates that the interface is for HyperSockets IPv4.

CHPID *chpid*

Use this parameter to specify the IQD CHPID for the HyperSockets interface. This value is a 2-character hexadecimal value (00x - FFx). The hexadecimal value specified on the CHPID parameter cannot be the same value that is used for the dynamic XCF HyperSockets interface. See the IQDCHPID start option in the [z/OS Communications Server: SNA Resource Definition Reference](#).

IPADDR *ipaddr_spec*

ipv4_address

The home IP address for this interface.

Requirement: The IP address must be specified in dotted decimal form.

num_mask_bits

An integer value in the range 0 - 32 that represents the number of leftmost significant bits for the subnet mask of the interface. The default is 0.

Requirement: If you are configuring multiple IPv4 VLAN interfaces to the same HyperSockets CHPID, then you must specify a nonzero value for the *num_mask_bits* variable for each of these interfaces and the resulting subnet must be unique for each of these interfaces.

Rule: If you are using OMROUTE and OMROUTE is not configured to ignore this interface, ensure that the subnet mask value that you define on this parameter matches the subnet mask used by OMROUTE for this interface. The subnet mask used by OMROUTE is the subnet mask value defined on the corresponding OMROUTE statement (OSPF_INTERFACE, RIP_INTERFACE,

or INTERFACE) for this interface. If no OMPROUTE statement is specified for this interface, the subnet mask used by OMPROUTE is the class mask for the interface IP address.

IPBCAST

Specifies that the interface both sends and receives IP broadcast packets. If this parameter is not specified, no IP broadcast packets are sent or received on this interface.

MTU *num*

The maximum transmission unit (MTU), in bytes. This value can be in the range 576 - 57344. The minimum MTU for IPv4 is 576. The stack takes the minimum of the configured value and the firmware supported value (which is the IQD frame size configured in HCD minus 8192)

The MTU default is equal to the IQD frame size minus 8192.

Rule: If you are using OMPROUTE and OMPROUTE is not configured to ignore this interface, ensure that the MTU that you define on this parameter matches the MTU used by OMPROUTE for this interface. The MTU used by OMPROUTE is the MTU value defined on the corresponding OMPROUTE statement (OSPF_INTERFACE, RIP_INTERFACE, or INTERFACE) for this interface. If an MTU value is not defined on the corresponding OMPROUTE statement for this interface or if no OMPROUTE statement is specified for this interface, the MTU used by OMPROUTE is the minimum MTU for IPv4 (576).

Tip: See [Determining the maximum transmission unit in z/OS Communications Server: IP Configuration Guide](#) for more information about how TCP/IP uses the MTU to determine the largest size frame to send.

READSTORAGE

An optional parameter that indicates the amount of fixed storage that z/OS CS should keep available for read processing for this interface. The IQDIOSTG VTAM start option allows you to specify a value that applies to all HiperSockets interfaces. You can use the READSTORAGE keyword to override the global IQDIOSTG value for this interface based on the inbound workload that you expect over this interface on this stack. The following values are valid:

GLOBAL

The amount of storage is determined by the IQDIOSTG VTAM start option. This is the default value.

MAX

Use this value if you expect a heavy inbound workload over this interface.

AVG

Use this value if you expect a medium inbound workload over this interface.

MIN

Use this value if you expect a light inbound workload over this interface.

Tip: See the description of the IQDIOSTG VTAM start option in the [z/OS Communications Server: SNA Resource Definition Reference](#) for details about exactly how much storage is allocated by z/OS Communications Server for each of these values.

Restriction: This parameter only takes effect when the IQD frame size is 64K.

VLANID *id*

An optional parameter followed by a decimal number indicating the virtual LAN identifier to be assigned to this HiperSockets interface. The valid range is 1 - 4 094.

SOURCEVIPINTERFACE *vipa_name*

An optional parameter used to specify which previously-defined VIPA interface is to be used for SOURCEVIPA (when IPCONFIG SOURCEVIPA is in effect). The *vipa_name* value is the interface name for a VIRTUAL interface.

Requirement: The VIRTUAL interface or the link must be defined prior to specifying this INTERFACE statement to the TCP/IP stack. It must either already be defined, or the INTERFACE statement (or DEVICE and LINK statements) that define the static VIPA must precede this INTERFACE statement in the profile data set.

Tip: The use of the SOURCEVIPINTERFACE parameter can be overridden. See the information about source IP selection in [z/OS Communications Server: IP Configuration Guide](#) for the hierarchy of ways that the source IP address of an outbound packet is determined.

SECCLASS security_class

Use this parameter to associate a security class for IP filtering with this interface. For traffic over the interface to match a filter rule, the filter rule must have the same security class value as the interface or a value of 0. Filter rules can be specified in the TCP/IP profile or in an IP Security policy file that is read by the Policy Agent. Filter rules can include a security class specification on the IpService statement in an IP Security policy file or on the SECCLASS parameter on the IPSECRULE statement in the TCP/IP profile.

Valid security classes are identified as a number in the range 1 - 255. The default value is 255. See [security class values in z/OS Communications Server: IP Configuration Guide](#) for more information.

Restriction: The TCP/IP stack ignores this value if IPSECURITY is not specified on the IPCONFIG statement.

MONSYSPLEX | NOMONSYSPLEX

Specifies whether or not sysplex autonomics should monitor the interface's status.

NOMONSYSPLEX

Specifies that sysplex autonomics should not monitor the interface's status. This is the default value.

MONSYSPLEX

Specifies that sysplex autonomics should monitor interface's status.

Restriction: The MONSYSPLEX attribute is not in effect unless the MONINTERFACE keyword is specified on the GLOBALCONFIG SYSPLEXMONITOR profile statement. The presence of dynamic routes over the interface is monitored if the DYNROUTE keyword is also specified on the GLOBALCONFIG SYSPLEXMONITOR profile statement.

SMCD | NOSMCD

Specifies whether this interface can be used with Shared Memory Communications - Direct Memory Access (SMC-D).

NOSMCD

Specifies that this interface cannot be used for new TCP connections with SMC-D.

SMCD

Specifies that this interface can be used for new TCP connections with SMC-D. This is the default setting.

Rule: SMCD has no effect unless a nonzero subnet mask is configured on the INTERFACE statement.

Guideline: If you enable Multipath and equal-cost interfaces are associated with different IP subnets, enabling SMC for some of, but not all, the interfaces can cause unpredictable SMC usage. You must specify either SMCD or NOSMCD on all equal-cost interfaces.

Steps for modifying

See [“Summary of INTERFACE statements” on page 80](#) for modification information.

Examples

```
INTERFACE HIPERSOCK1 DEFINE IPAQIDIO CHPID FC
IPADDR 9.1.1.1/24
```

Related topics

- [“BEGINROUTES statement” on page 19](#)
- [“DEVICE and LINK - MPCIPA HyperSockets devices statement” on page 41](#)

- [“INTERFACE - IPAQIDIO6 HiperSockets interfaces statement” on page 131](#)
- [“START statement” on page 242](#)
- [“STOP statement” on page 243](#)

INTERFACE - VIRTUAL interfaces statement

Use the **INTERFACE** statement to specify a static virtual interface.

You can define multiple virtual IPv4 addresses on one TCP/IP image by specifying multiple VIRTUAL INTERFACE statements.

Syntax

Interface Definition

➡ IPADDR — *ipv4_address* ➡

Parameters

intf_name

The name of the interface. The maximum length is 16 characters.

DEFINE

Specifies that this definition is to be added to the list of defined interfaces.

DELETE

Specifies that this definition is to be deleted from the list of defined interfaces. The *intf_name* must be the name of an interface previously defined by an INTERFACE statement. INTERFACE DELETE deletes all home IP addresses for the interface.

VIRTUAL

Indicates that the interface is not associated with real hardware and is used for fault tolerance support.

IPADDR *ipv4_address*

This parameter is required and must be one IPv4 address specified in dotted decimal form.

Steps for modifying

See “Summary of INTERFACE statements” on page 80 for modification information.

Examples

```
INTERFACE VIPAV4 DEFINE
  VIRTUAL
  IPADDR 9.1.1.1
```

Usage notes

- The TCP/IP stack does not maintain interface counters for VIRTUAL interfaces.
- A VIRTUAL interface name cannot be coded in the BEGINROUTES block.

Related topics

“IPCONFIG statement” on page 143

INTERFACE - EQENET6 Network Express Enhanced QDIO interfaces statement

Use the INTERFACE statement to specify a Network Express Enhanced QDIO Ethernet interface for IPv6.

Restriction: This statement applies to IPv6 IP addresses only.

To determine the Network Express microcode level, use the Netstat DEvlinks/-d report output. If a specific Network Express function is documented with a minimum microcode level, you can use this command to determine whether that function is supported. IBM service might request the microcode level for problem diagnosis. For more information, see [Netstat DEvlinks/-d report](#) in *z/OS Communications Server: IP System Administrator's Commands*.

When you start an EQENET6 interface (and you do not specify VMAC with ROUTEALL), TCP/IP registers all non-loopback local (home) IPv6 addresses for this TCP/IP instance to the Network Express feature. If you subsequently add, delete, or change any home IPv6 addresses on this TCP/IP instance, TCP/IP dynamically registers the changes to the Network Express feature. If stateless address autoconfiguration is enabled for this interface, TCP/IP dynamically registers autoconfigured addresses to the Network Express feature. This includes both public and temporary autoconfigured addresses. The Network Express feature routes datagrams destined to those IPv6 addresses to this TCP/IP instance.

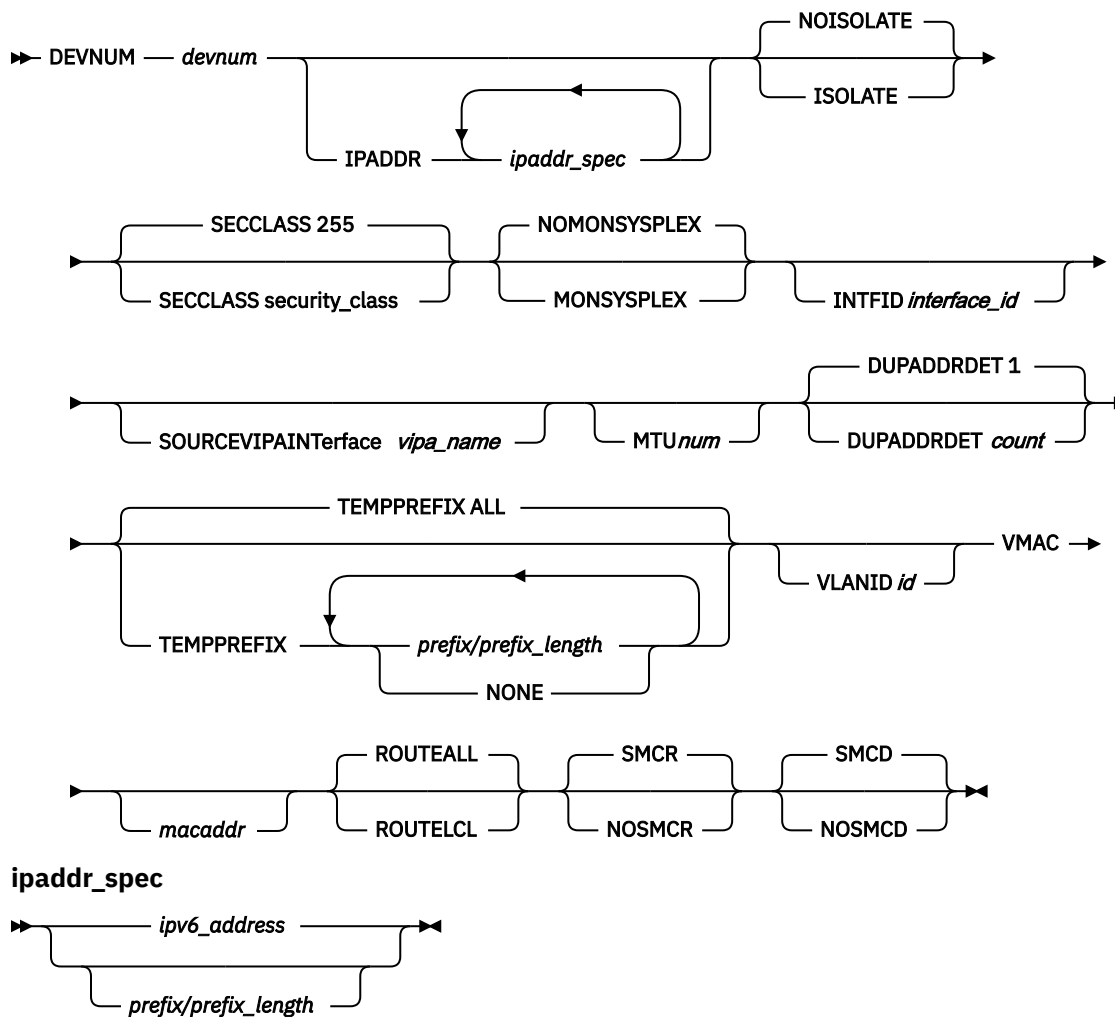

If a datagram is received by the OSA adapter for an unregistered IPv6 address, then the Network Express feature routes the datagram to the TCP/IP instance, depending on the setting of ROUTEALL or ROUTELCL on the virtual MAC (VMAC) address. If a datagram is received for this MAC address and the destination IP address has not been registered, then when using ROUTELCL, the datagram is discarded. When using ROUTEALL, the datagram will be processed. Typically, ROUTEALL is used when datagram forwarding is enabled for the stack.

Syntax

Rule: Specify the required parameters in the order shown here. The other parameters can be specified in any order.

Other parameters

Parameters

intf_name

The name of the interface. The maximum length is 16 characters.

Restriction: Do not specify the value PUBLICADDRS or TEMPADDRS for the interface name. The values PUBLICADDRS and TEMPADDRS are keywords on the SRCIP statement. These values are not recognized if they are specified as an IPv6 interface name on an SRCIP entry.

DEFINE

Specifies that this definition is to be added to the list of defined interfaces.

DELETE

Specifies that this definition is to be deleted from the list of defined interfaces. The *intf_name* must be the name of an interface previously defined by an INTERFACE statement. INTERFACE DELETE deletes all home IP addresses for the interface.

EQENET6

Indicates that the interface uses the interface based on IP assist, belongs to the Enhanced QDIO family of interfaces, and uses the Ethernet protocol.

DUPADDRDET *count*

Use this parameter to specify the number of times to attempt duplicate address detection. The minimum value is 0, maximum is 2 and default is 1. This is an optional parameter.

Guideline: A value of 0 means that TCP/IP does not perform duplicate address detection for this interface.

INTFID *interface_id*

An optional 64-bit interface identifier in colon-hexadecimal format. IPv6 shorthand is not allowed when specifying the interface ID. If specified, this interface ID is used to form the link-local address for the interface, and is also appended to any manually configured prefixes for the interface, to form complete IPv6 addresses on the interface. If you do not configure manual IP addresses on the interface, the INTFID value is appended to any prefixes that are learned over this interface by way of router advertisements to form public IPv6 addresses on the interface. The INTFID value is not used to form temporary IPv6 addresses. A randomly generated interface ID is appended to any learned prefixes to form temporary IPv6 addresses on the interface (if temporary addresses are enabled).

If INTFID is not coded, TCP/IP builds the Interface ID using information returned from the Network Express Adapter (during Interface activation). The built Interface ID value is then used to form the link-local address. This value is also used to complete the formation of other IPv6 addresses on the interface, if you choose to configure only the prefix portion of the addresses (by way of IPADDR). Also, if you do not configure manual IP addresses on the interface, the built interface ID value is appended to any prefixes learned over this interface by way of router advertisements to form public IPv6 addresses on the interface. The built interface ID value is not used to form temporary IPv6 addresses. A randomly generated interface ID is appended to any learned prefixes to form temporary IPv6 addresses on the interface (if temporary addresses are enabled).

When defining the interface ID, the local/universal flag (the U bit, bit 6 shown in the following example) must be set to 0. The group/individual flag (the G bit, bit 7 shown in the following example) must also be set to 0. If either flag is set incorrectly, interface definition fails. Additionally, an interface ID value correlating to an ISATAP address or a Reserved Anycast address is not allowed. (An ISATAP Interface ID has '00005EFE'x in bits 0 - 31, and a Reserved Anycast Interface ID has 'FCFFFFFFFFFFFF' in bits 0 - 56.)

	1 1	3 3	4 4	6
0	5 6	1 2	7 8	3
+	+	+	+	+
xxxxxxUGxxxxxxxx	xxxxxxxxxxxxxxxx	xxxxxxxxxxxxxxxx	xxxxxxxxxxxxxxxx	
+	+	+	+	+

IPADDR *ipaddr_spec*

The IPADDR parameter is optional, and is used to configure the interface's IPv6 addresses other than the link-local address, which is generated internally by TCP/IP. If IPADDR is not specified, TCP/IP enables IPv6 stateless autoconfiguration for the interface. For more information, see [Stateless address autoconfiguration](#) in *z/OS Communications Server: IPv6 Network and Appl Design Guide*.

Tip: Autoconfiguration is enabled if a router or some other device provides a router advertisement.

The following values can be specified for *ipaddr_spec*:

- *ipv6_addr* (A fully qualified IPv6 address is in colon-hexadecimal format.)
- *prefix/prefix_length*

The digits (in colon-hexadecimal format) before the / represent the prefix. The *prefix_length* represents the length of the prefix in bits. If a prefix length is coded, it must be equal to 64. When a prefix is specified, TCP/IP forms the IPv6 address by appending the interface ID to the specified prefix. The interface ID is either the value specified by way of the INTFID keyword, or the value formed by the stack using information returned by the device when the interface was started.

Restriction: If you code a prefix that is longer than 64 bits, it is truncated to 64 bits, and no error messages are issued.

For information about the IPv6 address restrictions, see [“Restrictions on IPv6 addresses configured in the TCP/IP profile”](#) on page 83

ISOLATE | NOISOLATE

Specifies whether packets should be directly routed between TCP/IP stacks that share the OSA adapter.

NOISOLATE

Route packets directly between TCP/IP stacks that share the OSA adapter. In this mode, if the next hop address was registered by another stack that is sharing the OSA, then Network Express routes the packet directly to the sharing stack without putting the packet on the external LAN.

ISOLATE

Prevent Network Express from routing packets directly to another TCP/IP stack that is sharing the OSA adapter. In this mode, Network Express discards any packets when the next hop address was registered by another stack that is sharing the OSA adapter. In this mode, packets can flow between two stacks that share the OSA adapter only by first going through a router on the LAN. For more details, see Network Express connection isolation information in [z/OS Communications Server: IP Configuration Guide](#).

Tip:

- If you isolate an INTERFACE, that action might have an adverse effect on latency.
- You can selectively apply Network Express connection isolation to individual virtual LANs.
- Network Express requires that both stacks sharing the port be non-isolated for direct routing to occur. Therefore, for traffic between two stacks sharing the OSA adapter, as long as at least one of the stacks is isolated, connection isolation is in effect for traffic in both directions between these stacks.

MONSYSPLEX | NOMONSYSPLEX

Specifies whether or not sysplex autonomics should monitor the interface's status.

NOMONSYSPLEX

Specifies that sysplex autonomics should not monitor the interfaces's status. This is the default value.

MONSYSPLEX

Specifies that sysplex autonomics should monitor the interface's status.

Restriction: The MONSYSPLEX attribute is not in effect unless the MONINTERFACE keyword is specified on the GLOBALCONFIG SYSPLEXMONITOR profile statement. The presence of dynamic routes over this interface is monitored if the DYNROUTE keyword is also specified on the GLOBALCONFIG SYSPLEXMONITOR profile statement.

MTU num

The maximum transmission unit (MTU) in bytes. This value can be up to 9000. The minimum MTU for IPv6 is 1280. The stack takes the minimum of the configured value and the value supported by the device (returned by the OSA adapter).

The MTU default, which depends on value supported by device, is 9000.

Tip: See [z/OS Communications Server: IP Configuration Guide](#), in section Maximum transmission unit considerations, for additional information about how TCP/IP uses the MTU to determine the largest size frame to send.

SMCD | NOSMCD

Specifies whether this interface can be used with Shared Memory Communications - Direct Memory Access (SMC-D).

NOSMCD

Specifies that this interface cannot be used for new TCP connections with SMC-D.

SMCD

Specifies that this interface can be used for new TCP connections with SMC-D. This is the default setting.

Guideline: If you enable Multipath and equal-cost interfaces are associated with different IP subnets, enabling SMC for some of, but not all, the interfaces can cause unpredictable SMC usage. You must specify either SMCD or NOSMCD on all equal-cost interfaces.

SMCR | NOSMCR

Specifies whether this interface can be used with Shared Memory Communications over Remote Direct Memory Access (SMC-R) for external data network communications.

NOSMCR

Specifies that this interface cannot be used for new TCP connections with SMC-R for external data network communications.

SMCR

Specifies that this interface can be used for new TCP connections with SMC-R for external data network communications. This is the default setting.

Rule: • SMCR has no effect unless at least one Peripheral Component Interconnect Express (PCIe) function ID (PFID) value is specified by using the PFID subparameter of the SMCR parameter on the GLOBALCONFIG statement.

Guideline: If you enable Multipath and equal-cost interfaces are associated with different IP subnets, enabling SMC for some of, but not all, the interfaces can cause unpredictable SMC usage. You must specify either SMCR or NOSMCR on all equal-cost interfaces.

SOURCEVIPAINTERFACE *vipa_name*

SOURCEVIPAINTERFACE is optional. Use this parameter to specify which previously defined static VIPA interface is to be used for SOURCEVIPA (when IPCONFIG6 SOURCEVIPA is in effect).

Tip: The use of the SOURCEVIPAINTERFACE parameter can be overridden. See the information about source IP address selection in [z/OS Communications Server: IP Configuration Guide](#) for the hierarchy of ways that the source IP address of an outbound packet is determined.

The *vipa_name* is the interface name for a VIRTUAL6 interface. If the VIPA has multiple IP addresses, then the sourcevipa address for outbound packets is selected from among these addresses according to the default source address selection algorithm. For more information, see [z/OS Communications Server: IPv6 Network and Appl Design Guide](#).

Requirement: The use of the SOURCEVIPAINTERFACE parameter can be overridden. See the information about source IP address selection in [z/OS Communications Server: IP Configuration Guide](#) for the hierarchy of ways that the source IP address of an outbound packet is determined.

TEMPPREFIX

TEMPPREFIX specifies the set of prefixes for which temporary IPv6 addresses can be generated. A temporary IPv6 address is generated when a router advertisement containing a prefix is processed and the prefix is included in one of the prefixes in the temporary prefix list. For example, if TEMPPREFIX 2001:0db8:58cd::/48 is specified for an interface, a temporary address is generated for advertised prefix 2001:0db8:58cd:0001/64; however, a temporary address is not generated for advertised prefix 2001:0db8:5555:0001/64.

ALL

Generate temporary addresses for all prefixes that are learned over this interface by way of router advertisements. ALL is the default.

NONE

No IPv6 temporary addresses are generated for this interface.

prefix/prefix_length

The digits (in colon-hexadecimal format) before the slash (/) represent the prefix. The *prefix_length* value represents the length of the prefix, in bits. Valid values for *prefix_length* are in the range 1 - 64.

Rules:

- Temporary addresses are generated only on an interface that is enabled for stateless address autoconfiguration.
- Temporary addresses are generated only when the TEMPADDRS keyword is specified on the IPCONFIG6 statement.

Requirement: You must specify the job name of an application in the SRCIP statement block with a value of TEMPADDRS to cause a temporary IPv6 address to be preferred over a public IPv6 address as the source IP address for the application; otherwise, the default source address selection algorithm prefers public IPv6 addresses over temporary addresses. For more information, see the information about the [default source address selection in z/OS Communications Server: IPv6 Network and Appl Design Guide](#).

VLANID id

Specifies the decimal virtual LAN identifier to be assigned to the Network Express INTERFACE. This field should be a virtual LAN identifier recognized by the switch for the LAN connected to this Network Express. The valid range is 1 - 4094. This parameter is optional.

Guideline: Installation configuration on other platforms or related to Ensemble networking can limit the maximum VLANID of 4096.

Datagrams that are received at this device instance for an unknown IP address are routed to this TCP/IP instance only if it is VLAN tagged with this VLAN ID and ROUTEALL is defined. For more information about VLANID parameter interactions, see [OSA VLAN in z/OS Communications Server: IP Configuration Guide](#).

Rule: If you are configuring multiple VLAN interfaces to the same Network Express feature, then you must specify the VMAC parameter (with the default ROUTEALL attribute) on the INTERFACE statement for each of these interfaces.

Restriction: The stack supports a maximum of 32 IPv6 VLAN interfaces to the same Network Express port. Additional VLANID limitations might exist if this interface can be used with Shared Memory Communications over Remote Direct Memory Access (SMC-R). See [VLANID considerations in z/OS Communications Server: IP Configuration Guide](#) for details.

VMAC macaddr

Specifies the virtual MAC address, which can be represented by 12 hexadecimal characters. The Network Express device uses this address rather than the physical MAC address of the device for all IPv6 packets to and from this TCP/IP stack. Using a virtual MAC address is required.

The *macaddr* value is optional. If the *macaddr* value is not coded, then the Network Express device generates a virtual MAC address. If the *macaddr* is coded, it must be defined as a locally administered individual MAC address. This means the MAC address must have bit 6 (the universal or local flag U bit) of the first byte set to 1 and bit 7 (the group or individual flag G bit) of the first byte set to 0. The second hexadecimal character must be 2, 6, A or E. The bit positions within the 12 hexadecimal characters are indicated as follows:

	1 1	3 3	4
0	5 6	1 2	7
+	+	+	+
xxxxxxUGxxxxxxxx	xxxxxxxxxxxxxxxx	xxxxxxxxxxxxxxxx	xxxxxxxxxxxxxxxx
+	+	+	+

Rules:

- The same virtual MAC address generated by the Network Express device at interface activation remains in effect for this Network Express for this TCP/IP stack, even if the interface is stopped or becomes inoperative (INOPs). A new Virtual MAC address is generated only if the INTERFACE statement is deleted and redefined, or if the TCP/IP stack is recycled.
- The NONROUTER, PRIROUTER, and SECROUTER parameters are ignored for a Network Express interface if the VMAC parameter is configured on the INTERFACE statement.

Guideline: Unless the virtual MAC address representing this Network Express device must remain the same even after TCP/IP termination and restart, configure VMAC without a *macaddr* value and allow the Network Express device to generate it. This guarantees that the VMAC address is unique from all other physical burned-in MAC addresses and from all other VMAC addresses generated by any Network Express feature.

ROUTEALL

Specifies that all IP traffic destined to the virtual MAC is forwarded by the Network Express device to the TCP/IP stack. This is the default value. See the [router information in z/OS Communications Server: IP Configuration Guide](#) for more details.

ROUTELCL

Specifies that only traffic destined to the virtual MAC and whose destination IP address is registered with the Network Express device by this TCP/IP stack is forwarded by the Network Express. See the [router information in z/OS Communications Server: IP Configuration Guide](#) for more details.

Steps for modifying

See [“Summary of INTERFACE statements” on page 80](#) for modification information.

Examples

```
INTERFACE OSHEQDIO26 ; OSA Enhanced QDIO
DEFINE EQENET6
DEVNUM 0172
SOURCEVIPAINIT VIPAV6
IPADDR 2001:0DB8:1:9:67:115:66      ; (Global Address)
VMAC
```

Related topics

- [“BEGINROUTES statement” on page 19](#)
- [“GLOBALCONFIG statement” on page 49](#)
- [“INTERFACE - IPAQENET OSA-Express QDIO interfaces statement” on page 84](#)
- [“START statement” on page 242](#)
- [“STOP statement” on page 243](#)

INTERFACE - IPAQENET6 OSA-Express QDIO interfaces statement

Use the INTERFACE statement to specify an OSA-Express QDIO Ethernet interface for IPv6.

To determine the OSA microcode level, use the DISPLAY TRL command. If a specific OSA function is documented with a minimum microcode level, you can use this command to determine whether that function is supported. IBM service might request the microcode level for problem diagnosis. For more information about the [DISPLAY TRL command](#), see [z/OS Communications Server: SNA Operation](#).

For more information about OSA features that support QDIO mode, see <https://www.ibm.com/docs/en/zos/2.3.0?topic=osa-z-systems-express-customers-guide-reference>.

When you start an IPAQENET6 interface (and you do not specify VMAC with ROUTEALL), TCP/IP registers all non-loopback local (home) IPv6 addresses for this TCP/IP instance to the OSA feature. If you subsequently add, delete, or change any home IPv6 addresses on this TCP/IP instance, TCP/IP dynamically registers the changes to the OSA feature. If stateless address autoconfiguration is enabled for this interface, TCP/IP dynamically registers autoconfigured addresses to the OSA feature. This includes both public and temporary autoconfigured addresses. The OSA feature routes datagrams destined to those IPv6 addresses to this TCP/IP instance.

If a datagram is received by the OSA adapter for an unregistered IPv6 address, then the OSA feature routes the datagram to the TCP/IP instance, depending on the setting of a virtual MAC (VMAC) address or whether the definition of an instance is PRIROUTER or SECROUTER. If the datagram is not destined for a virtual MAC address and no active TCP/IP instance using this interface is defined as PRIROUTER or SECROUTER, then the OSA feature discards the datagram. For more details about the OSA feature routing

considerations, see the router information in [z/OS Communications Server: IP Configuration Guide](#) and primary and secondary routing in [z/OS Communications Server: SNA Network Implementation Guide](#).

For detailed instructions on setting up an OSA feature, see <https://www.ibm.com/docs/en/zos/2.3.0?topic=osa-z-systems-express-customers-guide-reference>.

For more information about missing interrupt handler (MIH) considerations with TCP/IP interfaces, see “Missing interrupt handler factors” on page 37.

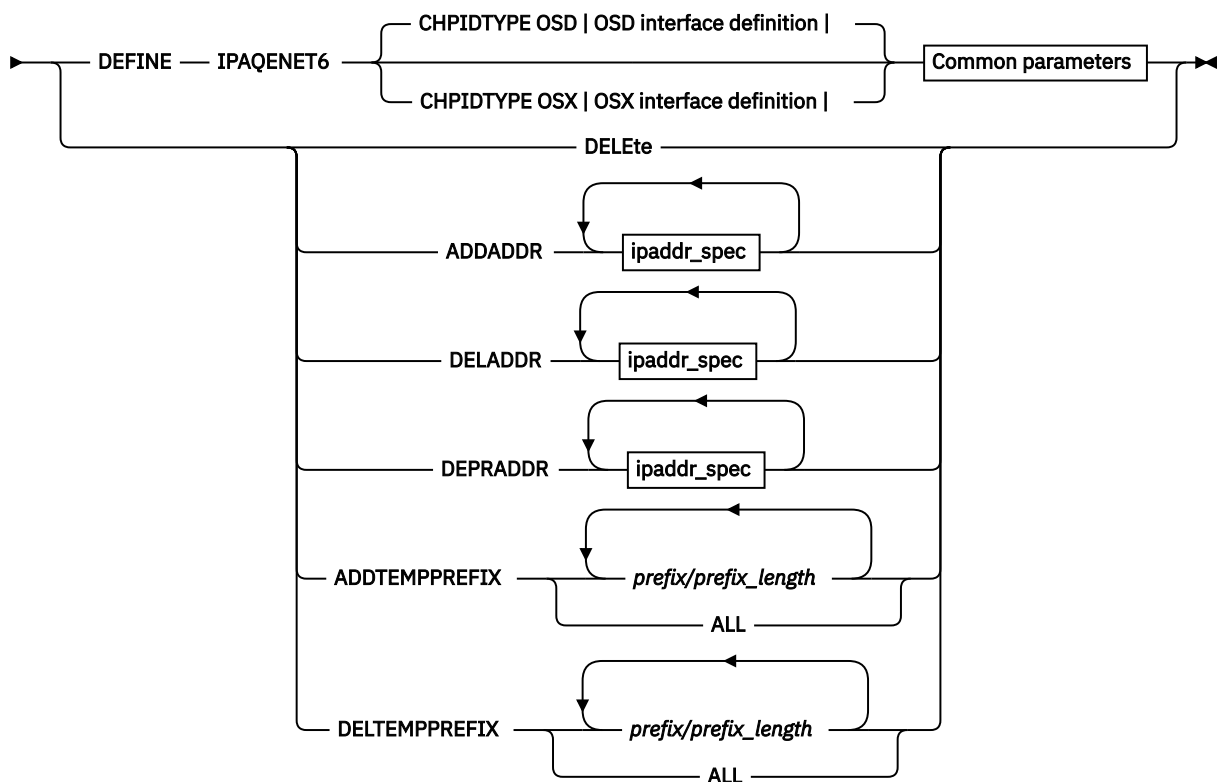

Restriction: This statement applies to IPv6 IP addresses only.

Note: For a list of all related OSA Express Best Practices for optimizing your performance for your OSA interface configuration, see [IBM z/OS Communications Server and OSA Express Best Practices](#).

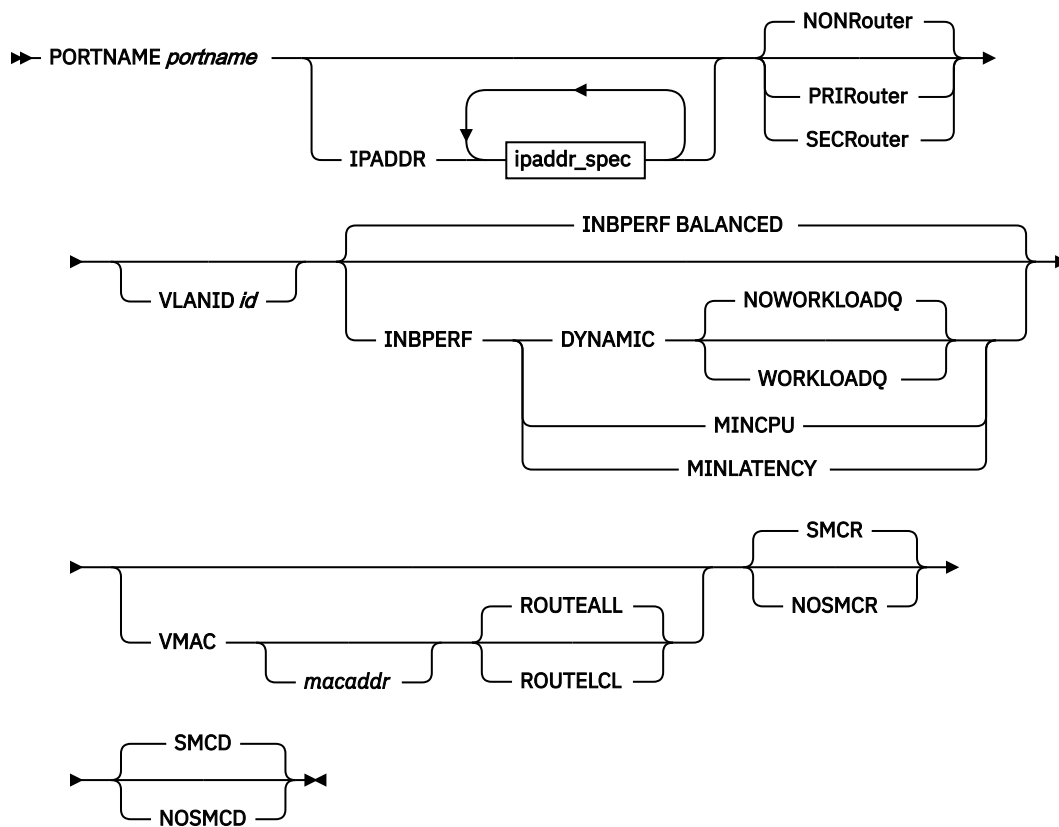

Syntax

Rule: Specify the required parameters and the CHPIDTYPE parameter in the order shown here. The OSD Interface Definition and OSX Interface Definition parameters can be specified in any order.

➤ INTERFace — *intf_name* ➤

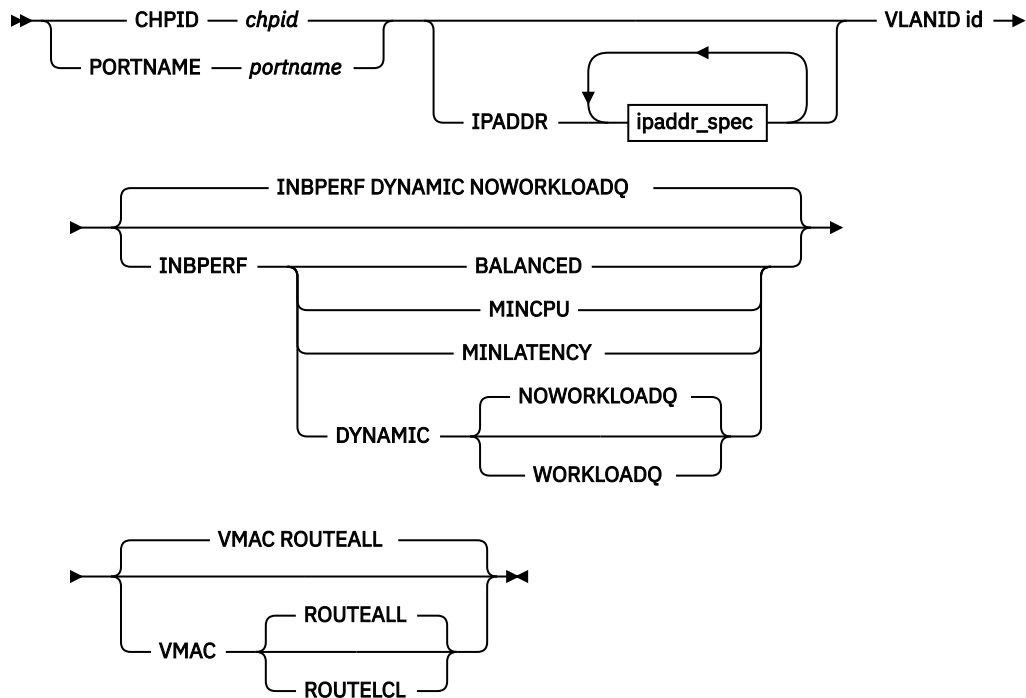

OSD interface definition

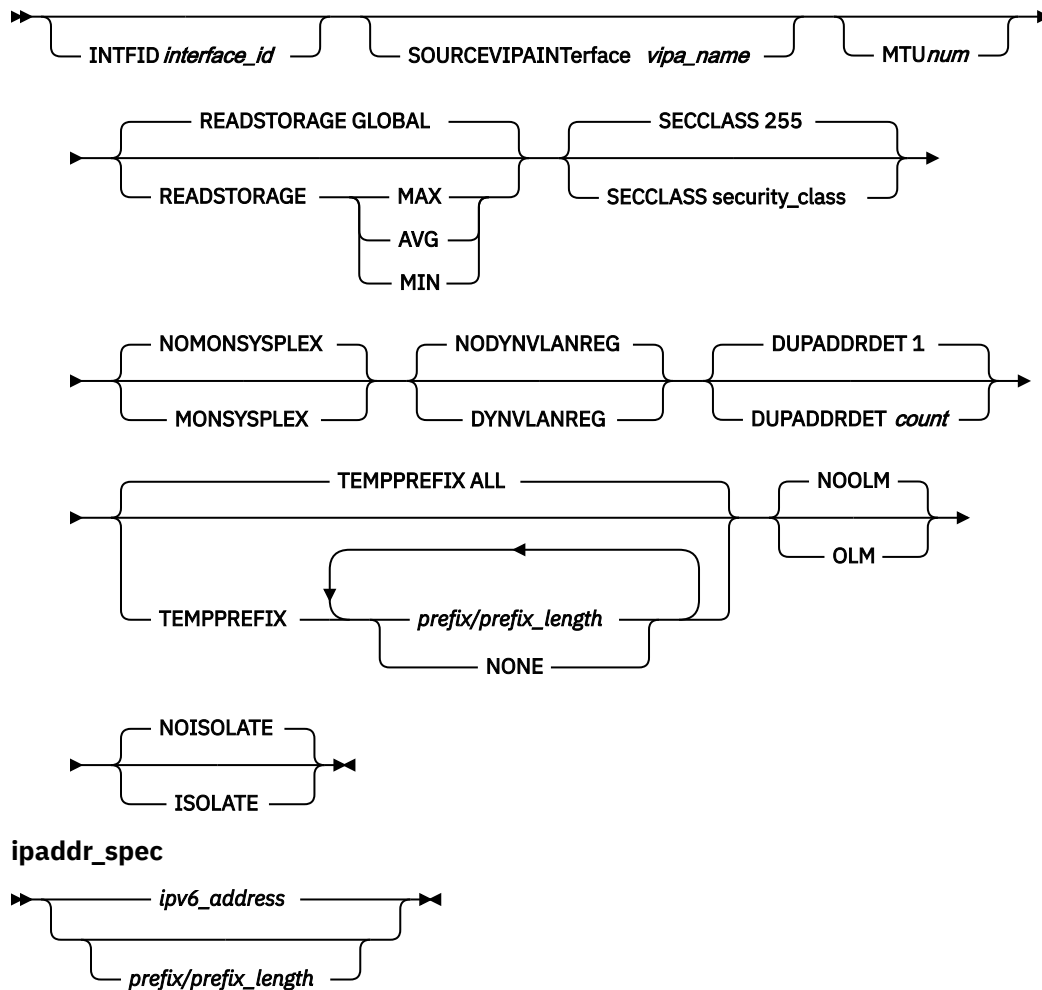

DEVNUM — *devnum* →

OSX Interface definition

Common parameters for OSD and OSX interface definitions

Parameters

intf_name

The name of the interface. The maximum length is 16 characters.

Requirement: This name must be different than the name specified for the PORTNAME parameter.

Restriction: Do not specify the value PUBLICADDRS or TEMPADDRS for the interface name. The values PUBLICADDRS and TEMPADDRS are keywords on the SRCIP statement. These values are not recognized if they are specified as an IPv6 interface name on an SRCIP entry.

DEFINE

Specifies that this definition is to be added to the list of defined interfaces.

DELETE

Specifies that this definition is to be deleted from the list of defined interfaces. The *intf_name* must be the name of an interface previously defined by an INTERFACE statement. INTERFACE DELETE deletes all home IP addresses for the interface.

CHPIDTYPE

An optional parameter indicating the CHPID type of the OSA-Express QDIO interface.

OSD

The external data network. This is the default value.

OSX

The intraensemble data network. See [z/OS Communications Server: IP Configuration Guide](#) for information about [requirements necessary to make an OSX work](#).

Rule: You must specify an OSD interface definition to make this OSA-Express QDIO interface eligible to use Shared Memory Communications over Remote Direct Memory Access (SMC-R) or Shared Memory Communications - Direct Memory Access (SMC-D).

IPADDR *ipaddr_spec*

The IPADDR parameter is optional, and is used to configure the interface's IPv6 addresses other than the link-local address, which is generated internally by TCP/IP. If IPADDR is not specified, TCP/IP enables IPv6 stateless autoconfiguration for the interface. For more information, see [Stateless address autoconfiguration in z/OS Communications Server: IPv6 Network and Appl Design Guide](#).

Tip: Autoconfiguration is enabled if a router or some other device provides a router advertisement.

The following values can be specified for *ipaddr_spec*:

- *ipv6_addr* (A fully qualified IPv6 address is in colon-hexadecimal format.)
- *prefix/prefix_length*

The digits (in colon-hexadecimal format) before the / represent the prefix. The *prefix_length* represents the length of the prefix in bits. If a prefix length is coded, it must be equal to 64. When a prefix is specified, TCP/IP forms the IPv6 address by appending the interface ID to the specified prefix. The interface ID is either the value specified by way of the INTFID keyword, or the value formed by the stack using information returned by the device when the interface was started.

Restriction: If you code a prefix that is longer than 64 bits, it is truncated to 64 bits, and no error messages are issued.

For information about the IPv6 address restrictions, see [“Restrictions on IPv6 addresses configured in the TCP/IP profile”](#) on page 83

ADDADDR *ipaddr_spec*

Allows the addition of IP addresses to an existing INTERFACE definition (similar to updating the HOME list with the VARY TCPIP,,OBEYFILE command) without having to delete and redefine the INTERFACE. This can be used to change the autoconfiguration state of an interface. If ADDADDR is coded and this is the first manually configured IP address for the interface, then TCP/IP disables autoconfiguration for the interface. The *intf_name* coded with ADDADDR must be the name of an interface previously defined by an INTERFACE statement.

Any public or temporary addresses that had previously been autoconfigured for the interface are deleted.

DELADDR *ipaddr_spec*

Allows you to delete IP addresses from an existing INTERFACE definition. If DELADDR is coded for the last or only manually configured IP address for an interface, then TCP/IP enables autoconfiguration for the interface. DELADDR is valid only for an IP address or prefix configured manually. The *intf_name* coded with DELADDR must be the name of an interface previously defined by an INTERFACE statement. DELADDR is valid only in a data set specified on a VARY TCPIP,,OBEYFILE command.

Guideline: If you specify a prefix for DELADDR, then the only IP addresses affected are those defined by way of the same prefix specified on IPADDR or ADDADDR.

DEPRADDR *ipaddr_spec*

The DEPRADDR keyword allows you to deprecate an IP address. This can assist with site renumbering. DEPRADDR is valid only for an IP address or prefix configured manually. If you use DEPRADDR to deprecate an IP address, you can subsequently use ADDADDR again to make that IP address preferred. For DEPRADDR, the *interface_name* must be the name of an interface previously defined by an INTERFACE statement. DEPRADDR is valid only in a data set specified on a VARY TCPIP,,OBEYFILE command.

Guideline: If you specify a prefix for DEPRADDR, then the only IP addresses affected are those defined by way of the same prefix specified on IPADDR or ADDADDR.

ADDTEMPPREFIX

Use the ADDTEMPPREFIX keyword to add prefixes to the temporary prefixes list of an existing INTERFACE definition without having to delete and redefine the INTERFACE statement. The

temporary prefixes list limits the set of prefixes for which temporary IPv6 addresses can be generated. A temporary IPv6 address is generated when a router advertisement containing the prefix is processed, and the prefix is included in one of the prefixes in the temporary prefixes list. For example, if the temporary prefixes list for an interface contains a single prefix 2001:0db8:58cd::/48, a temporary address is generated for advertised prefix 2001:0db8:58cd:0001/64; however, a temporary address is not generated on this interface for advertised prefix 2001:0db8:5555:0001/64. The *intf_name* variable coded with ADDTEMPPREFIX must be the name of an interface that was previously defined by an INTERFACE statement.

prefix/prefix_length

The digits (in colon-hexadecimal format) before the slash (/) represent the prefix. The *prefix_length* value represents the length of the prefix in bits. Valid values for *prefix_length* parameter are in the range 1 - 64.

ALL

Causes temporary addresses to be generated for all prefixes that are learned over this interface by way of router advertisements.

DELTEMPPREFIX

Use the DELTEMPPREFIX keyword to delete prefixes from the temporary prefixes list of an existing INTERFACE definition. The temporary prefixes list limits the set of prefixes for which temporary IPv6 addresses can be generated. A temporary IPv6 address is generated when a router advertisement containing the prefix is processed and the prefix is included in one of the prefixes in the temporary prefixes list. The *intf_name* variable coded with the DELTEMPPREFIX keyword must be the name of an interface that was previously defined by an INTERFACE statement.

prefix/prefix_length

The digits (in colon-hexadecimal format) before the slash (/) represent the prefix. The *prefix_length* value represents the length of the prefix in bits. Valid values for the *prefix_length* are in the range 1 - 64. All temporary addresses for this interface whose prefix is not included in the updated temporary prefixes list are deleted.

ALL

Delete all prefixes from the temporary prefixes list, which sets the temporary prefixes list to NONE. All temporary addresses for this interface are deleted, and no more temporary addresses are generated for this interface.

IPAQENET6

Indicates that the interface uses the interface based on IP assist, belongs to the QDIO family of interfaces, and uses the Gigabit Ethernet or Fast Ethernet protocol.

INTFID *interface_id*

An optional 64-bit interface identifier in colon-hexadecimal format. IPv6 shorthand is not allowed when specifying the interface ID. If specified, this interface ID is used to form the link-local address for the interface, and is also appended to any manually configured prefixes for the interface, to form complete IPv6 addresses on the interface. If you do not configure manual IP addresses on the interface, the INTFID value is appended to any prefixes that are learned over this interface by way of router advertisements to form public IPv6 addresses on the interface. The INTFID value is not used to form temporary IPv6 addresses. A randomly generated interface ID is appended to any learned prefixes to form temporary IPv6 addresses on the interface (if temporary addresses are enabled).

If INTFID is not coded, TCP/IP builds the Interface ID using information returned from the OSA Adapter (during Interface activation). The built Interface ID value is then used to form the link-local address. This value is also used to complete the formation of other IPv6 addresses on the interface, if you choose to configure only the prefix portion of the addresses (by way of IPADDR or ADDADDR). Also, if you do not configure manual IP addresses on the interface, the built interface ID value is appended to any prefixes learned over this interface by way of router advertisements to form public IPv6 addresses on the interface. The built interface ID value is not used to form temporary IPv6 addresses. A randomly generated interface ID is appended to any learned prefixes to form temporary IPv6 addresses on the interface (if temporary addresses are enabled).

When defining the interface ID, the local/universal flag (the U bit, bit 6 shown in the following example) must be set to 0. The group/individual flag (the G bit, bit 7 shown in the following example)

must also be set to 0. If either flag is set incorrectly, interface definition fails. Additionally, an interface ID value correlating to an ISATAP address or a Reserved Anycast address is not allowed. (An ISATAP Interface ID has '00005EFE'x in bits 0 - 31, and a Reserved Anycast Interface ID has 'FCFFFFFFFF' in bits 0 - 56.)

	1 1	3 3	4 4	6
0	5 6	1 2	7 8	3
+	+	+	+	+
xxxxxxUGxxxxxxxx	xxxxxxxxxxxxxxxx	xxxxxxxxxxxxxxxx	xxxxxxxxxxxxxxxx	
+	+	+	+	+

SOURCEVIPINTERFACE *vipa_name*

SOURCEVIPINTERFACE is optional. Use this parameter to specify which previously defined static VIPA interface is to be used for SOURCEVIPA (when IPCONFIG6 SOURCEVIPA is in effect).

Tip: The use of the SOURCEVIPINTERFACE parameter can be overridden. See the information about source IP address selection in [z/OS Communications Server: IP Configuration Guide](#) for the hierarchy of ways that the source IP address of an outbound packet is determined.

The *vipa_name* is the interface name for a VIRTUAL6 interface. If the VIPA has multiple IP addresses, then the sourcevipa address for outbound packets is selected from among these addresses according to the default source address selection algorithm. For more information, see [z/OS Communications Server: IPv6 Network and Appl Design Guide](#).

Requirement: The VIRTUAL6 interface must be defined prior to specifying this INTERFACE statement to the TCP/IP stack. It must either already be defined or, the INTERFACE statement that defines it must precede this INTERFACE statement in the profile data set.

CHPID *chpid*

This parameter applies only to interfaces of CHPIDTYPE OSX and is used to specify the CHPID for the interface. This value is a 2-character hexadecimal value (00 - FF).

PORTNAME *portname*

Use this parameter to specify the PORT name contained in the TRLE definition for the QDIO interface. The TRLE must be defined as MPCLEVEL=QDIO. For details about defining a TRLE, see [z/OS Communications Server: SNA Resource Definition Reference](#).

Requirement: The *portname* value must be different from the name that is specified for the *intf_name* value.

NONROUTER

If a datagram is received at this interface for an unknown IP address, the datagram is not routed to this TCP/IP instance. This is the default value.

PRIRouter and SECRouter parameters interact with the VLANID parameter. See the VLANID parameter to understand this relationship.

Rule: This keyword applies only to interfaces of CHPIDTYPE OSD and is ignored if the VMAC parameter is configured on the INTERFACE statement.

PRIROUTER

If a datagram is received at this interface for an unknown IP address and is not destined for a virtual MAC, the datagram is routed to this TCP/IP instance.

Rule: This keyword applies only to interfaces of CHPIDTYPE OSD and is ignored if the VMAC parameter is configured on the INTERFACE statement.

SECROUTER

If a datagram is received at this interface for an unknown IP address and is not destined for a virtual MAC, and there is no active TCP/IP instance defined as PRIROUTER, then the datagram is routed to this TCP/IP instance.

Rule: This keyword applies only to interfaces of CHPIDTYPE OSD and is ignored if the VMAC parameter is configured on the INTERFACE statement.

DUPADDRDET count

Use this parameter to specify the number of times to attempt duplicate address detection. The minimum value is 0, maximum is 2 and default is 1. This is an optional parameter.

Guideline: A value of 0 means that TCP/IP does not perform duplicate address detection for this interface.

MTU num

The maximum transmission unit (MTU) in bytes. This value can be up to 9000. The minimum MTU for IPv6 is 1280. The stack takes the minimum of the configured value and the value supported by the device (returned by the OSA adapter).

The MTU default, which depends on value supported by device, is the following value:

- Gigabit Ethernet default MTU = 9000
- Fast Ethernet default MTU = 1500

Tip: See [z/OS Communications Server: IP Configuration Guide](#), in section Maximum transmission unit considerations, for additional information about how TCP/IP uses the MTU to determine the largest size frame to send.

VLANID id

Specifies the decimal virtual LAN identifier to be assigned to the OSA INTERFACE. This field should be a virtual LAN identifier recognized by the switch for the LAN connected to this OSA. The valid range is 1 - 4094. This parameter is optional for CHPIDTYPE OSD and required for CHPIDTYPE OSX.

Guideline: Installation configuration on other platforms or related to Ensemble networking can limit the maximum VLANID of 4096.

The VLANID parameter interacts with the PRIRouter and SECRouter parameters. If you configure both the VLANID parameter and either PRIROUTER or SECROUTER parameter, then this TCP/IP instance acts as a router for this VLAN (ID) only. Datagrams that are received at this device instance for an unknown IP address and are not destined for a virtual MAC are routed only to this TCP/IP instance if it is VLAN tagged with this VLAN ID. For more information about VLANID parameter interactions, see [OSA VLAN](#) in [z/OS Communications Server: IP Configuration Guide](#).

Rule: If you are configuring multiple VLAN interfaces to the same OSA feature, then you must specify the VMAC parameter (with the default ROUTEALL attribute) on the INTERFACE statement for each of these interfaces.

Restriction: The stack supports a maximum of 32 IPv6 VLAN interfaces to the same OSA port. Additional VLANID limitations might exist if this interface can be used with Shared Memory Communications over Remote Direct Memory Access (SMC-R). See [VLANID considerations](#) in [z/OS Communications Server: IP Configuration Guide](#) for details.

READSTORAGE

An optional parameter indicating the amount of fixed storage that z/OS Communications Server should keep available for read processing for each input queue for this interface. Multiple input queues are used when WORKLOADQ is enabled. See description of the WORKLOADQ parameter for more details.

The QDIOSTG VTAM start option allows you to specify a value which applies to all OSA adapters in QDIO mode. You can use the READSTORAGE keyword to override the global QDIOSTG value for this adapter based on the inbound workload you expect over this interface on this stack. The valid values are:

GLOBAL

The amount of storage is determined by the QDIOSTG VTAM start option. This is the default value.

MAX

Use this value if you expect a heavy inbound workload over this interface.

AVG

Use this value if you expect a medium inbound workload over this interface.

MIN

Use this value if you expect a light inbound workload over this interface.

Tips:

- The amount of storage which corresponds to each of these values is different for an OSA with at least 25 GbE of bandwidth than for an OSA with less than 25 GbE of bandwidth. See [QDIOSTG start option in z/OS Communications Server: SNA Resource Definition Reference](#) for details about exactly how much storage is allocated by z/OS Communications Server for each of these values.
- The VTAM QDIOSTG start option or the READSTORAGE parameter, which overrides QDIOSTG, must be set to 126 (8 M) in order to support the OSA-Express Enhanced Inbound Blocking (EIB) function. For more information about the OSA-Express EIB function and using the VTAM QDIOEIB start option, see the [QDIOEIB start option in z/OS Communications Server: SNA Resource Definition Reference](#).
- For a list of all related OSA Express Best Practices for optimizing your performance for your OSA interface configuration, see [IBM z/OS Communications Server and OSA Express Best Practices](#).

Rule: If you define both a LINK and INTERFACE statement for the same adapter, then the READSTORAGE value on the LINK statement must match the READSTORAGE value on the corresponding INTERFACE statement. If you define an INTERFACE statement that contains a value for READSTORAGE that conflicts with the READSTORAGE value for a previous LINK statement for the same adapter, then TCP/IP rejects the INTERFACE statement.

INBPERF

An optional parameter that indicates how processing of inbound traffic for the QDIO interface is performed.

There are three supported static settings (MINCPU, MINLATENCY, and BALANCED).that indicate how frequently the adapter should interrupt the host for inbound traffic: BALANCED, MINCPU, and MINLATENCY. The static settings use static interrupt-timing values. The static values are not always optimal for all workload types or traffic patterns, and cannot account for changes in traffic patterns.

There is also one supported dynamic setting (DYNAMIC). This setting causes the host (stack) to dynamically adjust the timer-interrupt value while the device is active and in use. This function exploits an OSA hardware function called Dynamic LAN Idle. Unlike the static settings, the DYNAMIC setting reacts to changes in traffic patterns, and sets the interrupt-timing values at the point where throughput is maximized. In addition, the DYNAMIC setting uses the OSA Dynamic Router Architecture function to enable inbound workload queues for specific inbound traffic types.

Result: When you specify OLM on the INTERFACE statement, the INBPERF parameter is ignored and the statement defaults to the value DYNAMIC.

Valid values are:

BALANCED

This setting uses a static interrupt-timing value, which is selected to achieve reasonably high throughput and reasonably low CPU consumption. This is the default value for CHPIDTYPE OSD.

DYNAMIC

This setting causes the host to dynamically signal the OSA feature to change the timer-interrupt value, based on current inbound workload conditions. The DYNAMIC setting is effective only for OSA-Express2 or later features on at least an IBM System z9 that supports the corresponding Dynamic LAN Idle function. See the 2094DEVICE Preventive Service Planning (PSP) bucket and the 2096DEVICE Preventive Service Planning (PSP) bucket for more information about the level of OSA-Express2 adapter that supports this function. See the 2097DEVICE Preventive Service Planning (PSP) bucket for more information about the OSA-Express3 adapter that supports this function. The DYNAMIC setting can decrease latency and provide increases in throughput for many interactive workloads. For all other workload combinations, this setting provides performance similar to the three static settings. This is the default value for CHPIDTYPE OSX.

If the DYNAMIC setting is specified for an OSA-Express adapter that does not support the dynamic LAN Idle function, the stack reverts to using the BALANCED setting.

WORKLOADQ | NOWORKLOADQ

This sub parameter controls the inbound workload queuing function for the interface. Inbound workload queuing is effective only for OSA-Express features in QDIO mode that support the corresponding Data Router Architecture. OSA-Express features that support workload queuing do not necessarily support workload queuing for all possible traffic types. For more information about the inbound workload queuing function and the OSA-Express features that support it, see [QDIO inbound workload queueing in z/OS Communications Server: IP Configuration Guide](#).

NOWORKLOADQ

Specifies that inbound workload queuing is not enabled for inbound traffic. All inbound traffic for this interface uses a single input queue. This is the default.

WORKLOADQ

Specifies that inbound workload queuing (IWQ) is enabled for inbound traffic.

If the WORKLOADQ subparameter is specified, inbound workload queuing is enabled for specific inbound traffic types. A primary input queue is reserved for all other traffic types.

Ancillary input queues (AIQs) are created for the following inbound traffic types when supported by the OSA-Express feature:

- Sysplex distributor
- Streaming workloads (for example FTP)
- Enterprise Extender (EE)
- IP Security (IPSec)
- IBM z/OS Container Extensions (zCX)

Requirement: You must specify the VMAC parameter with WORKLOADQ to enable inbound workload queuing.

Restrictions:

- Bulk-mode TCP connection registration is supported only in configurations in which a single inbound interface is servicing the bulk-mode TCP connection. If a bulk-mode TCP connection detects that it is receiving data over multiple interfaces, Inbound workload queuing is disabled for the TCP connection and inbound data from that point forward is delivered to the primary input queue.
- Inbound workload queuing does not apply for traffic that is sent over an OSA port that is shared by the receiving TCP/IP stack when an indirect route (where the next hop and destination IP address are different) is being used; this traffic is placed on the primary input queue. Inbound workload queuing does apply when traffic on the shared OSA path uses a direct route (where the next hop and destination IP address are the same).

Guideline: The WORKLOADQ parameter requires an additional amount of fixed 4K CSM HVCOMMON storage per AIQ. The amount of storage consumed per AIQ is based on the amount of storage defined for READSTORAGE for this interface. The bulk AIQ is always backed with this additional CSM storage. The remaining AIQs are not backed by the additional CSM storage until the specific function (EE, SD, IPSec, or zCX) is used. The EE AIQ is backed by fixed 4K CSM DSPACE64 storage (instead of HVCOMMON). To verify the amount of CSM storage that is being used for each input queue, display the VTAM TRLE name that is associated with the interface. The WORKLOADQ parameter also requires an additional 36K of ECSA per AIQ.

Tip: The additional CSM storage consumed by each OSA interface using WORKLOADQ consumes fixed (real) storage. It is recommended that you verify that the additional fixed storage required by enabling WORKLOADQ (per OSA interface) will not approach any of the following limits:

- The CSM FIXED MAXIMUM value used by Communications Server (use the D NET, CSM command and see the CSM FIXED MAXIMUM value defined in IVTPRM00)

- The actual real storage available to this z/OS system (see D M=STOR or D M=HIGH)

If the WORKLOADQ setting is specified for an OSA-Express adapter that does not support the Data Router Architecture function, the stack reverts to using a single input queue.

MINCPU

This setting uses a static interrupt-timing value, which is selected to minimize host interrupts without regard to throughput. This mode of operation might result in minor queuing delays (latency) for packets into the host, which is not optimal for workloads with demanding latency requirements.

MINLATENCY

This setting uses a static interrupt-timing value, which is selected to minimize latency (delay), by more aggressively presenting received packets to the host. This mode of operation generally results in higher CPU consumption than the other three settings. Use this setting only if host CPU consumption is not an issue.

Rule: If you define both a LINK IPAQENET and an INTERFACE IPAQENET6 statement for the same adapter, then the following rules apply for the INBPERF parameter on these statements:

- The value on the LINK statement must match the INBPERF value on the corresponding INTERFACE statement.
- The INTERFACE statement supports the sub parameters WORKLOADQ and NOWORKLOADQ for the INBPERF DYNAMIC parameter. These sub parameters are associated with inbound workload queuing support and are not supported on the LINK IPAQENET statement. So, if you specify the INBPERF DYNAMIC parameter for both the LINK and the INTERFACE statements, then you must use the default or specify the NOWORKLOADQ sub parameter for the INBPERF DYNAMIC parameter on the INTERFACE statement. This ensures that the INBPERF DYNAMIC setting for both statements is the same.
- If you define an INTERFACE IPAQENET6 statement that contains a value for INBPERF that conflicts with the INBPERF value for a previous LINK IPAQENET statement for the same adapter, then TCP/IP rejects the INTERFACE statement.

Tip: The OSA-Express Enhanced Inbound Blocking function is dependent on the INBPERF setting for your interface. For more information about the OSA-Express EIB function and using the VTAM QDIOEIB start option, see the [QDIOEIB start option in z/OS Communications Server: SNA Resource Definition Reference](#).

SECCLASS *security_class*

Use this parameter to associate a security class for IP filtering with this interface. In order for traffic over the interface to match a filter rule, the filter rule must have the same security class value as the interface or a value of 0. Filter rules can be specified in the TCP/IP profile or in an IP Security policy file read by the Policy Agent. Filter rules can include a security class specification on the IpService statement in an IP Security policy file or on the SECCLASS parameter on the IPSEC6RULE statement in the TCP/IP profile.

Valid security classes are identified as a number in the range 1 - 255. The default value is 255. For more information about [security class values](#), see [z/OS Communications Server: IP Configuration Guide](#).

The TCP/IP stack ignores this value if IPSECURITY is not specified on the IPCONFIG6 statement.

MONSYSPLEX | NOMONSYSPLEX

Specifies whether or not sysplex autonomics should monitor the interface's status.

NOMONSYSPLEX

Specifies that sysplex autonomics should not monitor the interfaces's status. This is the default value.

MONSYSPLEX

Specifies that sysplex autonomics should monitor the interface's status.

Restriction: The MONSYSPLEX attribute is not in effect unless the MONINTERFACE keyword is specified on the GLOBALCONFIG SYSPLEXMONITOR profile statement. The presence of dynamic

routes over this interface is monitored if the DYNROUTE keyword is also specified on the GLOBALCONFIG SYSPLEXMONITOR profile statement.

DYNVLANREG | NODYNVLANREG

This parameter controls whether or not the VLAN ID for this interface is dynamically or statically registered with the physical switch on the LAN.

Restriction: This parameter is applicable only if a VLAN ID is specified on the statement.

Dynamic registration of VLAN IDs is handled by the OSA feature and the physical switch on your LAN. Therefore, in order for the DYNVLANREG parameter to be effective, both must be at a level which provides the necessary hardware support for dynamic VLAN ID registration. After the interface is active, you can view the Netstat DEvlinks/-d report output to determine if your OSA feature can support VLAN dynamic registration. This Netstat report also displays whether or not dynamic VLAN ID registration has been configured for the interface.

Rule: If you define both a LINK and INTERFACE statement for the same adapter, then the dynamic VLAN ID registration parameter value on the LINK statement must match the value of this same parameter on the corresponding INTERFACE statement. If you define an INTERFACE statement that contains a dynamic VLAN ID registration parameter value that conflicts with the same parameter value for a previous INTERFACE statement for the same OSA feature, then TCP/IP rejects the INTERFACE statement.

NODYNVLANREG

Specifies that if a VLAN ID is configured for this interface, it must be manually registered with the physical switches on the corresponding LAN. This is the default value. If this parameter is specified without a VLAN ID, then it is ignored.

DYNVLANREG

Specifies that if a VLAN ID is configured for this interface, it is dynamically registered with the physical switches on the corresponding LAN. If this parameter is specified without a VLAN ID, then warning message EZZ0056I is issued and the NODYNVLANREG setting is used instead.

VMAC *macaddr*

Specifies the virtual MAC address, which can be represented by 12 hexadecimal characters. The OSA device uses this address rather than the physical MAC address of the device for all IPv6 packets to and from this TCP/IP stack. For CHPIDTYPE OSD, using a virtual MAC address is optional. For CHPIDTYPE OSX, using a virtual MAC address is required, so the VMAC parameter is the default.

The *macaddr* value is optional for CHPIDTYPE OSD and cannot be specified for CHPIDTYPE OSX. If the *macaddr* value is not coded, then the OSA device generates a virtual MAC address. If the *macaddr* is coded, it must be defined as a locally administered individual MAC address. This means the MAC address must have bit 6 (the universal or local flag U bit) of the first byte set to 1 and bit 7 (the group or individual flag G bit) of the first byte set to 0. The second hexadecimal character must be 2, 6, A or E. The bit positions within the 12 hexadecimal characters are indicated as follows:

	1 1	3 3	4
0	5 6	1 2	7
+	-----+	-----+	-----+
xxxxxxUGxxxxxxxx	xxxxxxxxxxxxxxxx	xxxxxxxxxxxxxxxx	
+	-----+	-----+	-----+

Rules:

- The same virtual MAC address generated by the OSA device at interface activation remains in effect for this OSA for this TCP/IP stack, even if the interface is stopped or becomes inoperative (INOPs). A new Virtual MAC address is generated only if the INTERFACE statement is deleted and redefined, or if the TCP/IP stack is recycled.
- The NONROUTER, PRIROUTER, and SECROUTER parameters are ignored for an OSA-Express interface if the VMAC parameter is configured on the INTERFACE statement.

Guideline: Unless the virtual MAC address representing this OSA device must remain the same even after TCP/IP termination and restart, configure VMAC without a *macaddr* value and allow the

OSA device to generate it. This guarantees that the VMAC address is unique from all other physical burned-in MAC addresses and from all other VMAC addresses generated by any OSA feature.

Tip: If DEVNUM is coded on an IPAQENET6 interface statement and VMAC is not specified, the interface will default to VMAC ROUTEALL when the TCP/IP stack is started on a z17 or higher machine.

ROUTEALL

Specifies that all IP traffic destined to the virtual MAC is forwarded by the OSA device to the TCP/IP stack. This is the default value. See the [router information](#) in [z/OS Communications Server: IP Configuration Guide](#) for more details.

ROUTELCL

This specifies that only traffic destined to the virtual MAC and whose destination IP address is registered with the OSA device by this TCP/IP stack is forwarded by the OSA. See the [router information](#) in [z/OS Communications Server: IP Configuration Guide](#) for more details.

SMCR | NOSMCR

Specifies whether this interface can be used with Shared Memory Communications over Remote Direct Memory Access (SMC-R) for external data network communications.

NOSMCR

Specifies that this interface cannot be used for new TCP connections with SMC-R for external data network communications.

SMCR

Specifies that this interface can be used for new TCP connections with SMC-R for external data network communications. This is the default setting.

Rules:

- SMCR and NOSMCR are valid with CHPIDTYPE OSD definitions only.
- SMCR has no effect unless at least one Peripheral Component Interconnect Express (PCIe) function ID (PFID) value is specified by using the PFID subparameter of the SMCR parameter on the GLOBALCONFIG statement.

Guideline: If you enable Multipath and equal-cost interfaces are associated with different IP subnets, enabling SMC for some of, but not all, the interfaces can cause unpredictable SMC usage. You must specify either SMCR or NOSMCR on all equal-cost interfaces.

SMCD | NOSMCD

Specifies whether this interface can be used with Shared Memory Communications - Direct Memory Access (SMC-D).

NOSMCD

Specifies that this interface cannot be used for new TCP connections with SMC-D.

SMCD

Specifies that this interface can be used for new TCP connections with SMC-D. This is the default setting.

Rule: SMCD and NOSMCD are valid with CHPIDTYPE OSD definitions only.

Guideline: If you enable Multipath and equal-cost interfaces are associated with different IP subnets, enabling SMC for some of, but not all, the interfaces can cause unpredictable SMC usage. You must specify either SMCD or NOSMCD on all equal-cost interfaces.

DEVNUM *devnum*

This parameter applies to interfaces with CHPIDTYPE OSD specified and is only used for migration purposes. It is used to specify the device number that identifies the associated OSH CHPID of an Network Express feature. The first available device associated with the OSH CHPID is used for this interface. This value is a 4-character hexadecimal value (0000 - FFFF).

When specified, this parameter is used to conditionally migrate the QDIO (IPAQENET6) interface definition associated with an OSA-Express feature to an Enhanced QDIO (EQENET6) interface definition associated with an Network Express feature. If the TCP/IP stack is started on a System z16 or earlier machine, the DEVNUM keyword is ignored and activation of the IPAQENET interface

proceeds normally. If the TCP/IP stack is started on a z17 or higher machine, the DEVNUM keyword automatically converts your IPAQENET6 interface definition to an EQENET6 interface definition. For more information about migration scenarios, refer to the IP Configuration Guide.

Tips:

1. The device selected might not be the same as the device number specified. Netstat DEvlinks/-d displays the actual device number used.
2. Verify that your HCD I/O configuration specifies a sufficient number of OSH devices to support all of your defined interfaces associated with all the active stacks in this z/OS instance.
 - You must code a sufficient number of devices to accommodate the number of concurrent instances that will use an Network Express port. For each EQENET6 or IPAQENET6 statement that in your TCP/IP configurations that specifies DEVNUM for the same OSH CHPID, you must configure a device in the HCD. For example, within one TCP/IP stack profile, if you have three interface statements with DEVNUMs for the same OSH CHPID, then you will need three devices in the HCD for that OSH CHPID.
 - If you have multiple interface statements with DEVNUMs for the same shared OSA port, you must specify the same DEVNUM value on all the interface statements that are using the same shared OSA port. An available device associated with that port will be assigned to each interface. This is analogous to specifying the same portname for IPAQENET statements sharing the same OSA-Express port. For more information about OSA port sharing see OSA VLAN.
3. If DEVNUM is coded on an IPAQENET interface statement and VMAC is not specified, the interface will default to VMAC ROUTEALL when the TCP/IP stack is started on a z17 or higher machine.
4. If DEVNUM is coded on the IPAQENET INTERFACE statement and the interface is auto-migrated to EQENET, the IWQ function is automatically enabled. IWQ requires additional storage. If this IPAQENET INTERFACE statement did not specify INBPERF DYNAMIC WORKLOADQ (IWQ) then you will see a storage increase. For additional information, refer to the Guideline and Tip described under the INBPERF DYNAMIC WORKLOADQ parameter.

OLM| NOOLM

An optional parameter indicating whether an OSA adapter operates in optimized latency mode.

OLM

Specifies that the OSA adapter operates in optimized latency mode (OLM). Optimized latency mode optimizes interrupt processing for both inbound and outbound data. Use this mode for workloads that have demanding latency requirements. Because this mode can provide significant increases of throughput, this mode is particularly suited for interactive, non-streaming workloads. For more information about OLM, see [Optimized latency mode in z/OS Communications Server: IP Configuration Guide](#).

NOOLM

Specifies that the OSA-Express adapter should not operate in optimized latency mode. This is the default value.

Guidelines:

- Because of the operating characteristics of optimized latency mode, you might need to change configuration to direct traffic to particular OSA write priority queues and to limit the number of concurrent users sharing an OSA adapter configured for OLM. See [Optimized latency mode in z/OS Communications Server: IP Configuration Guide](#). for more information.
- The optimized latency mode function targets a z/OS environment with high-volume interactive workloads. Although optimized latency mode can compensate for some mixing of workloads, an excessive amount of high-volume streaming workloads, such as bulk data or file transfer, can result in higher CPU consumption.

Restrictions:

- This function is limited to OSA-Express3 or later Ethernet features in QDIO mode that are running with an IBM z10 or later. See the 2097 DEVICE Preventive Service Planning (PSP) bucket for more information.
- For an OSA configured to use optimized latency mode, the stack ignores the configured or default INBPERF setting and uses the value DYNAMIC.

NOISOLATE | ISOLATE

Specifies whether packets should be directly routed between TCP/IP stacks that share the OSA adapter.

NOISOLATE

Route packets directly between TCP/IP stacks that share the OSA adapter. In this mode, if the next hop address was registered by another stack that is sharing the OSA, then OSA routes the packet directly to the sharing stack without putting the packet on the external LAN.

ISOLATE

Prevent OSA-Express from routing packets directly to another TCP/IP stack that is sharing the OSA adapter. In this mode, OSA-Express discards any packets when the next hop address was registered by another stack that is sharing the OSA adapter. In this mode, packets can flow between two stacks that share the OSA adapter only by first going through a router on the LAN. For more details, see OSA connection isolation information in [z/OS Communications Server: IP Configuration Guide](#).

Tips:

- If you isolate an INTERFACE, that action might have an adverse effect on latency.
- You can selectively apply OSA connection isolation to individual virtual LANs.
- OSA requires that both stacks sharing the port be non-isolated for direct routing to occur. Therefore, for traffic between two stacks sharing the OSA adapter, as long as at least one of the stacks is isolated, connection isolation is in effect for traffic in both directions between these stacks.

Restriction: This function is limited to OSA-Express2 or later Ethernet features in QDIO mode and running at least an IBM System z9 Enterprise Class (EC) or z9 Business Class (BC). See the 2094, 2096, 2097, or 2098 DEVICE Preventive Service Planning (PSP) and the 2096DEVICE Preventive Service Planning (PSP) buckets for more information.

TEMPPREFIX

TEMPPREFIX specifies the set of prefixes for which temporary IPv6 addresses can be generated. A temporary IPv6 address is generated when a router advertisement containing a prefix is processed and the prefix is included in one of the prefixes in the temporary prefix list. For example, if TEMPPREFIX 2001:0db8:58cd::/48 is specified for an interface, a temporary address is generated for advertised prefix 2001:0db8:58cd:0001/64; however, a temporary address is not generated for advertised prefix 2001:0db8:5555:0001/64.

ALL

Generate temporary addresses for all prefixes that are learned over this interface by way of router advertisements. ALL is the default.

NONE

No IPv6 temporary addresses are generated for this interface.

prefix/prefix_length

The digits (in colon-hexadecimal format) before the slash (/) represent the prefix. The *prefix_length* value represents the length of the prefix, in bits. Valid values for *prefix_length* are in the range 1 - 64.

Rules:

- Temporary addresses are generated only on an interface that is enabled for stateless address autoconfiguration.
- Temporary addresses are generated only when the TEMPADDRS keyword is specified on the IPCONFIG6 statement.

Requirement: You must specify the job name of an application in the SRCIP statement block with a value of TEMPADDRS to cause a temporary IPv6 address to be preferred over a public IPv6 address as the source IP address for the application; otherwise, the default source address selection algorithm prefers public IPv6 addresses over temporary addresses. For more information, see the information about the [default source address selection](#) in *z/OS Communications Server: IPv6 Network and Appl Design Guide*.

Steps for modifying

See [“Summary of INTERFACE statements” on page 80](#) for modification information.

Examples

```
INTERFACE OSAQDIO26 ; OSA QDIO (Fast Ethernet)
DEFINE IPAQENET6
PORTNAME OSAQDIO2
SOURCEVIPAINIT VIPAV6
IPADDR 2001:0DB8:1:9:67:115:66 ; (Global Address)
```

Usage notes

Restriction: For each interface, the PRIROUTER and SECROUTER attributes can be in effect for only one TCP/IP instance within a central processor complex (CPC). If PRIROUTER is specified for an IPAQENET6 interface, but the IPv6 primary router attribute is already in effect on another TCP/IP instance for the same OSA, then TCP/IP issues a warning message during interface activation and ignores the PRIROUTER parameter. Therefore, only one TCP/IP instance can be the primary router for the OSA. Depending on the level of OSA being started, either only one or multiple TCP/IP instances can be allowed to have SECROUTER specified. If OSA allows only one secondary router, any TCP/IP instance subsequently starting that interface with SECROUTER receives a warning message during START processing for the interface. If OSA allows multiple secondary routers, then OSA can select any TCP/IP instance which specifies SECROUTER as the secondary router. There is no requirement that the same TCP/IP instance be specified PRIROUTER or SECROUTER for all OSA adapters attached to the CPC.

Rule: To configure a single OSA port for both IPv4 and IPv6 traffic, consider the following conditions:

- If you use DEVICE/LINK/HOME for the IPv4 definition and INTERFACE for the IPv6 definition, the PORTNAME value on the INTERFACE statement must match the device_name on the DEVICE statement. This combination shares a single DATAPATH device.
- If you use INTERFACE for both IPv4 and IPv6 definitions, the PORTNAME value on the IPv4 INTERFACE statement must match the PORTNAME value on the IPv6 INTERFACE statement. This combination results in separate DATAPATH devices.

Related topics

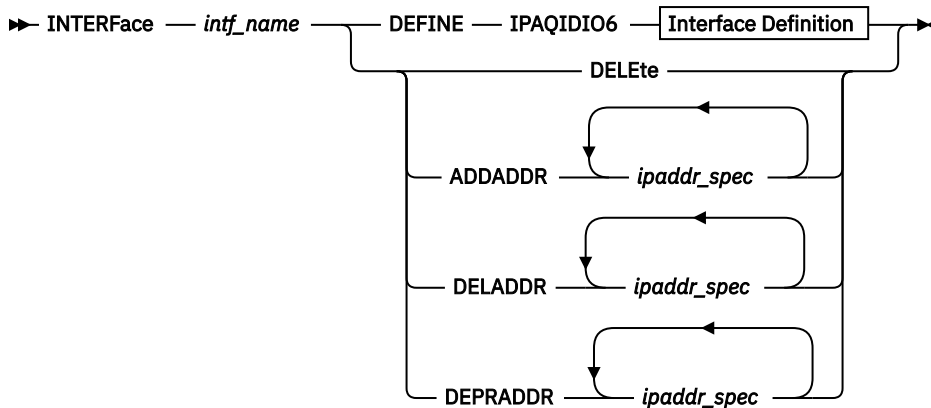

- [“BEGINROUTES statement” on page 19](#)
- [“GLOBALCONFIG statement” on page 49](#)

- [“START statement” on page 242](#)
- [“STOP statement” on page 243](#)

INTERFACE - IPAQIDIO6 HiperSockets interfaces statement

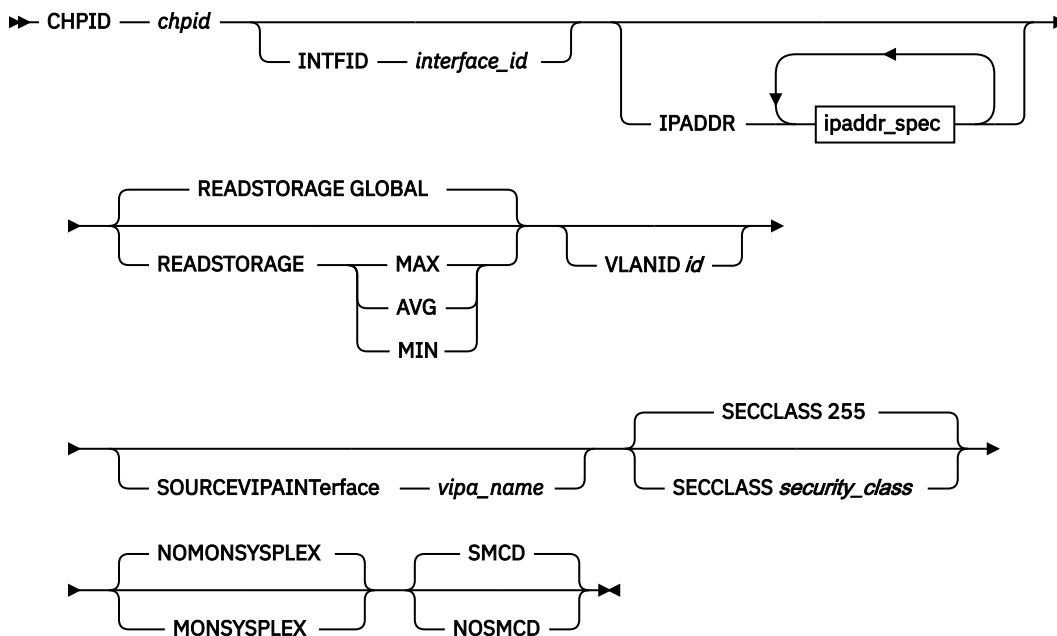

Use the INTERFACE statement for IPAQIDIO6 to configure IPv6 HiperSockets connectivity. Use the CHPID parameter to specify the value of the desired IQD CHPID that was configured within HCD. HiperSockets interfaces do not require a corresponding TRLE definition. Instead, the TRLE is dynamically built when the interface is started.

Rule: Specify the required parameters in the order shown here. The Interface Definition parameters can be specified in any order.

Syntax

Interface Definition

ipaddr_spec

Parameters

intf_name

The name of the interface. The maximum length is 16 characters.

Restriction: Do not specify the value PUBLICADDRES or TEMPADDRES for the interface name. The values PUBLICADDRES and TEMPADDRES are keywords on the SRCIP statement. These values are not recognized if they are specified as an IPv6 interface name on an SRCIP entry.

DEFINE

Specifies that this definition is to be added to the list of defined interfaces.

DELETE

Specifies that this definition is to be deleted from the list of defined interfaces. The *intf_name* must be the name of an interface previously defined by an INTERFACE statement. INTERFACE DELETE deletes all home IP addresses for the interface.

ADDADDR *ipaddr_spec*

Adds IP addresses to an existing INTERFACE definition (similar to an obeyfile to update the home list) without having to delete and redefine the INTERFACE. The interface name (*intf_name*) coded with ADDADDR must be the name of an interface previously defined by an INTERFACE statement.

DELADDR *ipaddr_spec*

Deletes IP addresses from an existing INTERFACE definition. The DELADDR parameter is valid only for an IP address or prefix configured manually. The interface name (*intf_name*) coded with DELADDR must be the name of an interface previously defined by an INTERFACE statement. DELADDR is valid only in a VARY OBEYFILE profile.

Guideline: If you specify a prefix for DELADDR, then the only IP addresses affected are those defined by way of the same prefix specified on IPADDR or ADDADDR.

DEPRADDR *ipaddr_spec*

The DEPRADDR keyword allows you to deprecate an IP address. This can assist with site renumbering. DEPRADDR is valid only for an IP address or prefix configured manually. If you use DEPRADDR to deprecate an IP address, you can subsequently use ADDADDR again to make that IP address preferred. For DEPRADDR, the *interface_name* must be the name of an interface previously defined by an INTERFACE statement. DEPRADDR is valid only in a VARY OBEYFILE profile.

Guideline: If you specify a prefix for DEPRADDR, then the only IP addresses affected are those defined by way of the same prefix specified on IPADDR or ADDADDR.

IPADDR *ipaddr_spec*

The IPADDR parameter is optional, and is used to configure the interface's IPv6 addresses other than the link-local address (which is generated internally by TCP/IP).

Rule: Stateless Address Autoconfiguration does not apply to IPAQIDIO6 interfaces, you must manually configure any addresses (other than link-local) that are to be assigned to the IPAQIDIO6 interface.

If ADDADDR, DELADDR, DEPRADDR, or IPADDR is specified, then *ipaddr_spec* can be one of the following:

- *ipv6_addr* (A fully qualified IPv6 address in colon-hexadecimal format)
- *prefix/prefix_length*. Here, the digits (in colon-hexadecimal format) before the / represent the prefix. The prefix length represents the length of the prefix in bits. If a prefix length is coded, it must be equal to 64. When a prefix is specified, TCP/IP forms the IPv6 address by appending an interface ID to the specified prefix. The selected interface ID is either the value specified by way of the INTFID keyword, or the value returned by the device when the interface was started.

For information about the IPv6 address restrictions, see [“Restrictions on IPv6 addresses configured in the TCP/IP profile” on page 83](#).

IPAQIDIO6

Indicates that the interface is for HiperSockets IPv6.

INTFID *interface_id*

An optional 64-bit interface identifier in colon-hexadecimal format.

If specified, this interface ID is used to form the link-local address for the interface, and is also appended to any manually configured prefixes for the interface, to form complete IPv6 addresses on the interface.

If INTFID is not coded, TCP/IP builds the Interface ID using information returned from the HiperSockets device (during interface activation). The built Interface ID value is then used to form the link-local address. This value is also used to complete the formation of other IPv6 addresses on the interface, if you choose to configure only the prefix portion of the addresses (by way of IPADDR or ADDADDR).

When defining the interface ID, the local/universal flag (the U bit, bit 6 shown in the following example) must be set to 0. The group/individual flag (the G bit, bit 7 shown in the following example) must also be set to 0. If either flag is set incorrectly, interface definition fails. Additionally, an interface ID value correlating to an ISATAP address or a Reserved Anycast address is not allowed. (An ISATAP Interface ID has '00005EFE'x in bits 0 - 31, and a Reserved Anycast Interface ID has 'FCFFFFFFFFFFFF' in bits 0 - 56.)

	1 1	3 3	4 4	6
0	5 6	1 2	7 8	3
+	+	+	+	+
xxxxxxUGxxxxxxx	xxxxxxxxxxxxxxxx	xxxxxxxxxxxxxxxx	xxxxxxxxxxxxxxxx	
+	+	+	+	+

SOURCEVIPINTERFACE *vipa_name*

SOURCEVIPINTERFACE is optional. Use this to specify which previously defined VIPA interface is to be used for SOURCEVIP (when IPCONFIG6 SOURCEVIP is in effect).

Tip: The use of the SOURCEVIPINTERFACE parameter can be overridden. See the information about source IP address selection in [z/OS Communications Server: IP Configuration Guide](#) for the hierarchy of ways that the source IP address of an outbound packet is determined.

The *vipa_name* is the interface name for a VIRTUAL6 interface. If the VIPA has multiple IP addresses, then the sourcevip address for outbound packets is selected from among these addresses according to the default source address selection algorithm. For more information, see the [default source address selection](#) information in [z/OS Communications Server: IPv6 Network and Appl Design Guide](#).

Requirement: The VIRTUAL6 interface must be defined prior to specifying this INTERFACE statement to the TCP/IP stack. It must either already be defined or, the INTERFACE statement that defines it must precede this INTERFACE statement in the profile data set.

SECCLASS *security_class*

Use this parameter to associate a security class for IP filtering with this interface. In order for traffic over the interface to match a filter rule, the filter rule must have the same security class value as the interface or a value of 0. Filter rules can be specified in the TCP/IP profile or in an IP Security policy file read by the Policy Agent. Filter rules can include a security class specification on the IpService statement in an IP Security policy file or on the SECCLASS parameter on the IPSEC6RULE statement in the TCP/IP profile.

Valid security classes are identified as a number in the range 1 - 255. The default value is 255.

For more information about [security class values](#), see [z/OS Communications Server: IP Configuration Guide](#).

Restriction: The TCP/IP stack ignores this value if IPSECURITY is not specified on the IPCONFIG6 statement.

MONSYSPLEX | NOMONSYSPLEX

Specifies whether or not sysplex autonomics should monitor the interface's status.

NOMONSYSPLEX

Specifies that sysplex autonomics should not monitor the interface's status. This is the default value.

MONSYSPLEX

Specifies that sysplex autonomics should monitor tinterface's status.

Restriction: The MONSYSPLEX attribute is not in effect unless the MONINTERFACE keyword is specified on the GLOBALCONFIG SYSPLEXMONITOR profile statement. The presence of dynamic routes over the interface is monitored if the DYNROUTE keyword is also specified on the GLOBALCONFIG SYSPLEXMONITOR profile statement.

SMCD | NOSMCD

Specifies whether this interface can be used with Shared Memory Communications - Direct Memory Access (SMC-D).

NOSMCD

Specifies that this interface cannot be used for new TCP connections with SMC-D.

SMCD

Specifies that this interface can be used for new TCP connections with SMC-D. This is the default setting.

Guideline: If you enable Multipath and equal-cost interfaces are associated with different IP subnets, enabling SMC for some of, but not all, the interfaces can cause unpredictable SMC usage. You must specify either SMCD or NOSMCD on all equal-cost interfaces.

The following interface-specific values can be specified for IPAQIDIO6.

CHPID *chpid*

Use this parameter to specify the IQD CHPID for the HiperSockets interface. This value is a 2-character hexadecimal value (00x - FFx). The hexadecimal value specified on the CHPID parameter cannot be the same value that is used for the dynamic XCF HiperSockets interface. See [IQDCHPID start option](#) in the [z/OS Communications Server: SNA Resource Definition Reference](#).

READSTORAGE

An optional parameter indicating the amount of fixed storage that z/OS CS should keep available for read processing for this interface. The IQDIOSTG VTAM start option allows you to specify a value which applies to all HiperSockets devices. You can use the READSTORAGE keyword to override the global IQDIOSTG value for this interface based on the inbound workload you expect over this interface on this stack. The valid values are:

GLOBAL

The amount of storage is determined by the IQDIOSTG VTAM start option. This is the default value.

MAX

Use this value if you expect a heavy inbound workload over this interface.

AVG

Use this value if you expect a medium inbound workload over this interface.

MIN

Use this value if you expect a light inbound workload over this interface.

Tip: See the description of [IQDIOSTG](#) in the [z/OS Communications Server: SNA Resource Definition Reference](#) for details about exactly how much storage is allocated by z/OS Communications Server for each of these values.

Restriction: This parameter only takes effect when the IQD frame size is 64K.

Rules:

- If you define both a LINK and INTERFACE statement for the same device, then the READSTORAGE value on the LINK statement must match the READSTORAGE value on the corresponding INTERFACE statement.
- If you define an INTERFACE statement which contains a value for READSTORAGE which conflicts with the READSTORAGE value for a previous LINK statement for the same device, then TCP/IP rejects the INTERFACE statement.

VLANID *id*

An optional parameter followed by a decimal number indicating the virtual LAN identifier to be assigned to this HiperSockets interface. The valid range is 1 - 4094.

Restriction: HiperSockets allows a stack to specify only one VLAN ID if you define IPv4 connectivity by using DEVICE and LINK statements and also configure an IPv6 INTERFACE statement for the same CHPID. In this case, if you specify a different VLAN ID value on a LINK or INTERFACE definition for the same CHPID, the second statement is rejected.

Steps for modifying

See [“Summary of INTERFACE statements” on page 80](#) for modification information.

Examples

```
INTERFACE HIPERSOCK1 DEFINE IPAQIDIO6 CHPID FC
IPADDR 12AB::7
```

Usage notes

Rule: To configure a single HiperSockets CHPID for both IPv4 and IPv6 traffic, consider the following conditions:

- If you use DEVICE/LINK/HOME for the IPv4 definition and INTERFACE for the IPv6 definition, the CHPID value on the INTERFACE statement must match the xx portion of the device_name (IUTIQDxx) on the DEVICE statement. This combination shares a single DATAPATH device.
- If you use INTERFACE for both IPv4 and IPv6 definition, the CHPID value on the IPv4 INTERFACE statement must match the CHPID value on the IPv6 INTERFACE statement. This combination results in separate DATAPATH devices.

Related topics

- [“BEGINROUTES statement” on page 19](#)
- [“DEVICE and LINK - MPCIPA HiperSockets devices statement” on page 41](#)

- [“START statement” on page 242](#)
- [“STOP statement” on page 243](#)

INTERFACE - LOOPBACK6 interface statement

There is only one LOOPBACK6 interface. The default LOOPBACK6 address ::1 is generated automatically and cannot be deleted. Therefore, you cannot DEFINE or DELETE the LOOPBACK6 interface. However, you can add additional IP addresses for LOOPBACK6 in the initial profile or by using the VARY TCPIP,,OBEYFILE command. Additionally, you can delete and deprecate one or more of these additional IP addresses by using the VARY TCPIP,,OBEYFILE command.

Rule: Specify the required parameters in the order shown here. The optional parameters can be specified in any order.

Syntax

Parameters

ADDADDR

Allows the addition of IP addresses to an existing LOOPBACK6 definition (similar to updating the HOME list with a VARY TCPIP,,OBEYFILE command) without having to delete and redefine the INTERFACE.

If ADDADDR is specified, then *ipaddr_spec* can be one or more full IPv6 addresses.

ipaddr_spec

For information about the IPv6 address restrictions, see [“Restrictions on IPv6 addresses configured in the TCP/IP profile”](#) on page 83.

The following value can be specified for *ipaddr_spec*:

ipv6_address

IPv6 address in colon-hexadecimal format.

DELADDR *ipaddr_spec*

Allows you to delete IP addresses from an existing LOOPBACK6 definition.

If DELADDR is specified, then *ipaddr_spec* can be one or more full IPv6 addresses.

Restriction: You cannot code DELADDR to delete the default LOOPBACK6 address ::1.

DEPRADDR *ipaddr_spec*

The DEPRADDR keyword allows you to deprecate an IP address. This can assist with site renumbering. If you use DEPRADDR to deprecate an IP address, you can subsequently use ADDADDR again to make that IP address preferred.

DEPRADDR is valid only for an IP address configured manually.

Examples

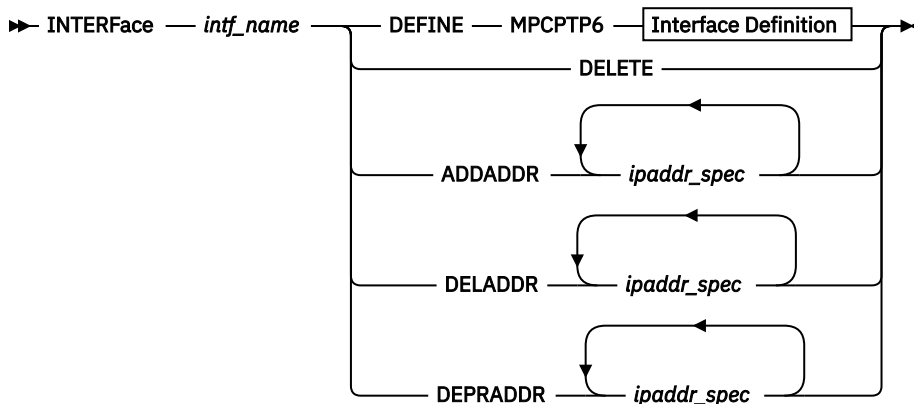

```
INTERFACE LOOPBACK6 ADDADDR ::0014:0
```

INTERFACE - MPCPTP6 interfaces statement

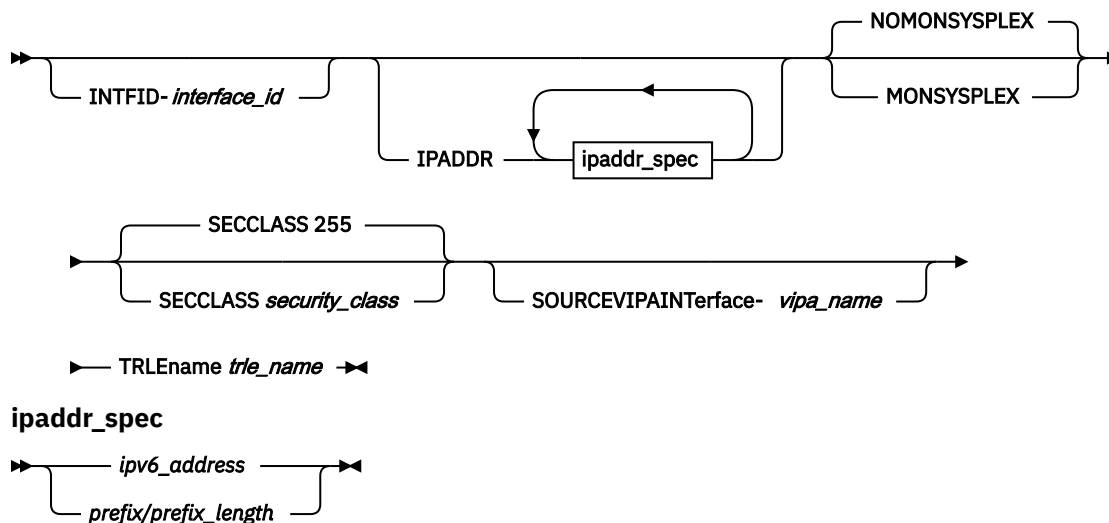

The MPC Point-To-Point Data Link Control supports IPv6 traffic. With this support, interface type MPCPTP6 can be used to carry IPv6 traffic over ESCON channels, over XCF links in a sysplex, or between z/OS Communications Server images using the simulated device provided by the IUTSAMEH function in VTAM.

Rule: Specify the required parameters in the order shown here. The Interface Definition parameters can be specified in any order.

Syntax

Interface Definition

Parameters

intf_name

The name of the interface. The maximum length is 16 characters.

Restriction: Do not specify the value PUBLICADDRS or TEMPADDRS for the interface name. The values PUBLICADDRS and TEMPADDRS are keywords on the SRCIP statement. These values are not recognized if they are specified as an IPv6 interface name on an SRCIP entry.

DEFINE

Specifies that this definition is to be added to the list of defined interfaces.

DELETE

Specifies that this definition is to be deleted from the list of defined interfaces. The *intf_name* must be the name of an interface previously defined by an INTERFACE statement. INTERFACE DELETE deletes all home IP addresses for the interface.

ipaddr_spec

For information about the IPv6 address restrictions, see [“Restrictions on IPv6 addresses configured in the TCP/IP profile”](#) on page 83.

The following value can be specified for *ipaddr_spec*:

- *ipv6_addr* (A fully qualified IPv6 address in colon-hexadecimal format)
- *prefix/prefix_length*. Here, the digits (in colon-hexadecimal format) before the / represent the prefix. The prefix length represents the length of the prefix in bits. If a prefix length is coded, it must be equal to 64. When a prefix is specified, TCP/IP forms the IPv6 address by appending an interface ID to the specified prefix. The selected interface ID is either the value specified by way of the INTFID keyword, or a random value that was generated at the time the interface was started.

ADDADDR *ipaddr_spec*

Allows the addition IP addresses to an existing INTERFACE definition (similar to updating the HOME list with a VARY TCPIP,,OBEYFILE command) without having to delete and redefine the INTERFACE. The *intf_name* coded with ADDADDR must be the name of an interface previously defined by an INTERFACE statement.

DELADDR *ipaddr_spec*

Allows you to delete IP addresses from an existing INTERFACE definition. The *intf_name* coded with DELADDR must be the name of an interface previously defined by an INTERFACE statement.

Guideline: If you specify a prefix for DELADDR, then the only IP addresses affected are those defined by way of the same prefix specified on IPADDR or ADDADDR.

DEPRADDR *ipaddr_spec*

Allows you to deprecate an IP address. This can assist with site renumbering. If you use DEPRADDR to deprecate an IP address, you can subsequently use ADDADDR to once again make that IP address preferred. The *intf_name* coded with DEPRADDR must be the name of an interface previously defined by an INTERFACE statement.

Guideline: If you specify a prefix for DEPRADDR, then the only IP addresses affected are those defined by way of the same prefix specified on IPADDR or ADDADDR.

MPCPTP6

Indicates that this interface operates as a MultiPath Channel connection for IPv6 traffic.

INTFID *interface_id*

An optional 64-bit interface identifier in colon-hexadecimal format. IPv6 shorthand is not allowed when specifying the interface ID. If specified, this interface ID is used to form the link-local address for the interface, and is also appended to any manually-configured prefixes for the interface, to form complete IPv6 addresses on the interface.

If INTFID is not coded, TCP/IP generates a random value to be used to form the link-local address. This random value is also used to complete the formation of other IPv6 addresses on the interface, if you choose to configure only the Prefix portion of the addresses (by way of IPADDR or ADDADDR).

When defining the interface ID, the local/universal flag (the U bit, bit 6 shown in the following example) must be set to 0. The group/individual flag (the G bit, bit 7 shown in the following example) must also be set to 0. If either flag is set incorrectly, interface definition fails. Additionally, an interface ID value correlating to an ISATAP address or a Reserved Anycast address is not allowed. (An ISATAP Interface ID has '00005EFE'x in bits 0 - 31, and a Reserved Anycast Interface ID has 'FCFFFFFFFFFFFF8' in bits 0 - 56.)

	1 1	3 3	4 4	6
0	5 6	1 2	7 8	3
+	+	+	+	+
xxxxxxxxUGxxxxxxxx	xxxxxxxxxxxxxxxx	xxxxxxxxxxxxxxxx	xxxxxxxxxxxxxxxx	
+	+	+	+	+

MONSYSPLEX | NOMONSYSPLEX

Specifies whether or not sysplex autonomics should monitor the interface's status.

NOMONSYSPLEX

Specifies that sysplex autonomics should not monitor the interface's status. This is the default value.

MONSYSPLEX

Specifies that sysplex autonomics should monitor the interface's status.

Restriction: The MONSYSPLEX attribute is not in effect unless the MONINTERFACE keyword is specified on the GLOBALCONFIG SYSPLEXMONITOR profile statement. The presence of dynamic routes over this interface is monitored if the DYNROUTE keyword is also specified on the GLOBALCONFIG SYSPLEXMONITOR profile statement.

SECCLASS *security_class*

Use this parameter to associate a security class for IP filtering with this interface. In order for traffic over the interface to match a filter rule, the filter rule must have the same security class value as the interface or a value of 0. Filter rules can be specified in the TCP/IP profile or in an IP Security policy file read by the Policy Agent. Filter rules can include a security class specification on the IpService statement in an IP Security policy file or on the SECCLASS parameter on the IPSEC6RULE statement in the TCP/IP profile.

Valid security classes are identified as a number in the range 1 - 255. The default value is 255.

For more information about security class values, see z/OS Communications Server: IP Configuration Guide.

Restriction: The TCP/IP stack ignores this value if the IPSECURITY parameter is not specified on the IPCONFIG6 statement.

SOURCEVIPINTERFACE *vipa_name*

The SOURCEVIPINTERFACE parameter is optional. It specifies which previously defined static VIPA interface is to be used for SOURCEVIPA (when IPCONFIG6 SOURCEVIPA is specified).

Tip: The use of the SOURCEVIPINTERFACE parameter can be overridden. See the information about source IP address selection in [z/OS Communications Server: IP Configuration Guide](#) for the hierarchy of ways that the source IP address of an outbound packet is determined.

The *vipa_name* value is the interface name for a VIRTUAL6 interface. If the VIPA has multiple IP addresses, then the source VIPA address for outbound packets is selected from among these addresses according to the default source address selection algorithm. For more information, see the [default source address selection information in z/OS Communications Server: IPv6 Network and Appl Design Guide](#).

Requirement: The VIRTUAL6 interface must be defined prior to specifying this INTERFACE statement to the TCP/IP stack. It must either already be defined or, the INTERFACE statement that defines it must precede this INTERFACE statement in the profile data set.

TRLENAME *trle_name*

The *trle_name* value must be the TRLE name of an HPDT connection. The TRLE is defined in a VTAM TRL major node and must be active before the interface can be started. For details about defining a TRLE, see [z/OS Communications Server: SNA Resource Definition Reference](#).

The maximum length of the *trle_name* value is eight characters.

TRLE Name Specification for IP samehost, Enterprise Extender, and sysplex connections:

Specifying the reserved TRLE name IUTSAMEH allows for IPv6 communications over a samehost MPC point-to-point connection between the local TCP/IP stack and one or more TCP/IP stacks running on the same z/OS image. No physical device is needed to provide this connection between the stacks; VTAM provides a simulated communications link. VTAM dynamically defines the IUTSAMEH TRLE.

When running Enterprise Extender over an IPv6 network, you must define and start an MPCPTP6 interface, specifying the IUTSAMEH TRLE. This is not required if you specify IPCONFIG6 DYNAMICXCF.

For XCF connections, the *trle_name* must be the CP name of the target VTAM on the other side of the XCF connection, and the VTAM ISTLSXCF major node must be active in both nodes to start the device.

IPADDR *ipaddr_spec*

The IPADDR parameter is optional, and is used to configure the interface's IPv6 addresses other than the link-local address (which is generated internally by TCP/IP).

Rule: Stateless Address Autoconfiguration does not apply to MPCPTP6 interfaces, so you must manually configure any addresses (other than link-local) that are to be assigned to the MPCPTP6 interface.

Steps for modifying

See [“Summary of INTERFACE statements” on page 80](#) for modification information.

Examples

```
INTERFACE MPCPTPV6A DEFINE MPCPTP6 TRLENAME ESCONCT1
INTFID 0:0:0:1 IPADDR 12AB:0:0:0::/64
```

Usage notes

Requirement: IUTSAMEH definition is required if you plan to use the Enterprise Extender function over an IPv6 network, and the TCP/IP stack you are configuring is used for access to the IP network by VTAM on this host.

Restriction: A mix of static and dynamic IPv4 and IPv6 definitions for a device is not allowed. For example, if a static IUTSAMEH IPv4 device and link is defined, an IPv6 dynamic definition for IUTSAMEH

is not created. If a static IUTSAMEH IPv6 interface is defined, an IPv4 dynamic definition for IUTSAMEH is not created. The same logic also applies for XCF links; a mix of static and dynamic IPv4 and IPv6 definitions is not allowed for an XCF link.

Rule: In order to configure a single physical device for both IPv4 and IPv6 traffic, you must use DEVICE/LINK/HOME for the IPv4 definition and INTERFACE for the IPv6 definition, such that the TRLENAM value on the INTERFACE statement matches the device_name on the DEVICE statement.

INTERFACE - VIRTUAL6 interfaces statement

Use the INTERFACE statement to specify a static virtual interface.

You can define multiple virtual IPv6 addresses on one TCP/IP image either by specifying multiple addresses on one VIRTUAL6 INTERFACE statement or by specifying multiple VIRTUAL6 INTERFACE statements.

Rule: Specify the required parameters in the order shown here. The optional parameters can be specified in any order.

Syntax

Interface Definition

Parameters

intf_name

The name of the interface. The maximum length is 16 characters.

Restriction: Do not specify the value PUBLICADDRS or TEMPADDRS for the interface name. The values PUBLICADDRS and TEMPADDRS are keywords on the SRCIP statement. These values are not recognized if they are specified as an IPv6 interface name on an SRCIP entry.

DEFINE

Specifies that this definition is to be added to the list of defined interfaces.

DELETE

Specifies that this definition is to be deleted from the list of defined interfaces. The *intf_name* must be the name of an interface previously defined by an INTERFACE statement. INTERFACE DELETE deletes all home IP addresses for the interface.

ADDADDR *ipaddr_spec*

Allows the addition of IP addresses to an existing INTERFACE definition (similar to updating the HOME list with a VARY TCPIP,,OBEYFILE command), without having to delete and redefine the INTERFACE. The *intf_name* coded with ADDADDR must be the name of an interface previously defined by an INTERFACE statement.

If ADDADDR is specified, then *ipaddr_spec* can be one or more full IPv6 addresses.

ipaddr_spec

For information about the IPv6 address restrictions, see [“Restrictions on IPv6 addresses configured in the TCP/IP profile” on page 83](#).

The following value can be specified for *ipaddr_spec*:

ipv6_address

IPv6 address in colon-hexadecimal format.

DELADDR *ipaddr_spec*

Allows you to delete IP addresses from an existing INTERFACE definition. The *intf_name* coded with DELADDR must be the name of an interface previously defined by an INTERFACE statement.

If DELADDR is specified, then *ipaddr_spec* can be one or more full IPv6 addresses.

Restriction: You cannot code DELADDR and delete the last IP address for a VIRTUAL6 interface. You must delete the interface itself by specifying an INTERFACE statement for the interface name, with the DELETE parameter.

DEPRADDR *ipaddr_spec*

The DEPRADDR keyword allows you to deprecate an IP address. This can assist with site renumbering. If you use DEPRADDR to deprecate an IP address, you can subsequently use ADDADDR again to make that IP address preferred. For DEPRADDR, the interface_name must be the name of an interface previously defined by an INTERFACE statement.

VIRTUAL6

Indicates that the interface is not associated with real hardware and is used for fault tolerance support.

IPADDR *ipaddr_spec*

This parameter is required and must be one or more full IPv6 addresses (no prefix is allowed).

Steps for modifying

See [“Summary of INTERFACE statements” on page 80](#) for modification information.

Examples

```
INTERFACE VIPAV6 DEFINE
VIRTUAL6
IPADDR 12AB::1
12AB::2
```

Usage notes

- The TCP/IP stack does not maintain interface counters for VIRTUAL6 interfaces.
- A VIRTUAL6 interface name cannot be coded in the BEGINROUTES block.

Related topics

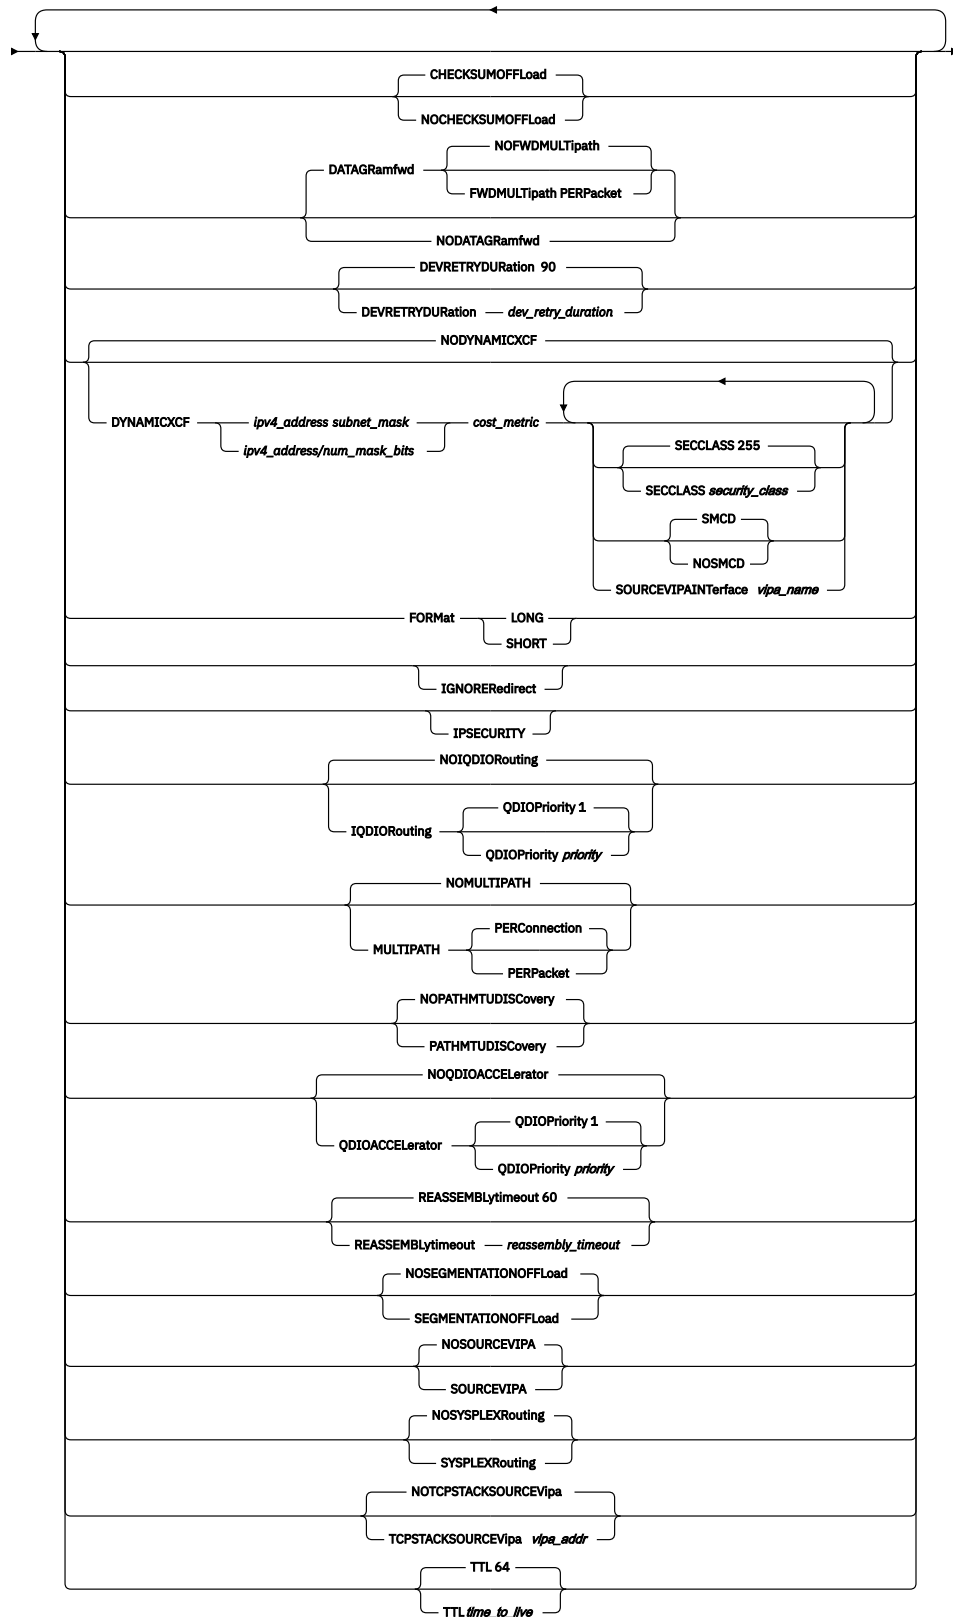

[“IPCONFIG6 statement” on page 156](#)

IPCONFIG statement

Use the IPCONFIG statement to update the IPv4 IP layer of TCP/IP.

Syntax

Tip: Specify the parameters for this statement in any order.

Parameters

CHECKSUMOFFLOAD | NOCHECKSUMOFFLOAD

Specifies whether the stack should offload inbound and outbound checksum processing (IP header, TCP, and UDP checksums) for IPv4 packets to OSA features. The checksum offload support transfers the overhead of most checksum processing to OSA devices that support this function. Offloading checksum processing reduces CPU use and increases throughput.

See “Steps for modifying” on page 154 for information about changing this parameter while the TCP/IP stack is active. See Checksum offload in *z/OS Communications Server: IP Configuration Guide* for more information about the checksum offload support and for specific information about which packets can have checksum processing performed by the OSA.

NOCHECKSUMOFFLOAD

Checksum processing is performed by the TCP/IP stack.

CHECKSUMOFFLOAD

Checksum processing is offloaded to the OSA feature. This value is the default value.

DATAGRAMFWD | NODATAGRAMFWD

NODATAGRAMFWD

Disables the forwarding of IP packets that are received by, but not addressed to, the stack. This statement can be used for security or to ensure correct usage of limited resources. The NODATAGRAMFWD parameter is confirmed by the message:

```
EZZ0334I IP FORWARDING IS DISABLED
```

DATAGRAMFWD

Enables the forwarding of IP packets that are received by, but not addressed to, the stack. This is the default value.

Tip: The FWDMULTIPATH and NOFWDMULTIPATH keywords used with DATAGRAMFWD are independent of the MULTIPATH keyword on the IPCONFIG statement.

NOFWDMULTIPATH

When forwarding is in effect and there are multiple equal-cost routes to the destination and the NOFWDMULTIPATH parameter is specified, TCP/IP uses the first active route found for forwarding each IP packet. This is the default value. The DATAGRAMFWD NOFWDMULTIPATH parameter is confirmed by the message:

```
EZZ0641I IP FORWARDING NOFWDMULTIPATH SUPPORT IS ENABLED
```

FWDMULTIPATH PERPACKET

When forwarding is in effect and there are multiple equal-cost routes to the destination and the FWDMULTIPATH PERPACKET parameter is specified, TCP/IP selects a route for forwarding each IP packet on an approximate round-robin basis from the multiple equal-cost routes. The selected route is used for routing that IP packet. Connection or connectionless-oriented IP packets using the same destination address do not always use the same route, but they do use all possible active routes to that destination host. All IP packets for a given association with a destination host are spread across the multiple equal-cost routes. The DATAGRAMFWD FWDMULTIPATH PERPACKET parameter is confirmed by the message:

```
EZZ0641I IP FORWARDING FWDMULTIPATH PERPACKET SUPPORT IS ENABLED
```

Guideline: If the TCP/IP stack is also configured to be a sysplex distributor (see “VIPADYNAMIC statement summary” on page 253 for more information), datagrams destined to a sysplex-distributed dynamic VIPA are forwarded to stacks, whether or not forwarding is enabled.

DEVRETRYDURATION *dev_retry_duration*

Specifies the duration (in seconds) of the retry period for a failed device or interface. TCP/IP performs reactivation attempts at 30 second intervals during this retry period. The default for DEVRETRYDURATION is 90 seconds. A specification of 0 generates an infinite recovery period, which means reactivation attempts are performed until the device or interface is either successfully

reactivated or manually stopped (by way of the VARY TCPIP,,STOP command, or the VARY TCPIP,,OBEYFILE command with a data set containing the STOP profile statement). The maximum specifiable value is 4294967295.

Guideline: The default 90-seconds retry duration is sufficient for transparent recovery following many types of device or channel errors. However, certain ESCON-attached routers cannot complete a microcode load in 90 seconds and installations might want to increase the DEVRETRYDURATION to automatically recover the device following these longer outages. On the other hand, installations running extensive automation built upon SNMP status and alerts can choose to code a small (nonzero) value in DEVRETRYDURATION, such that device recovery is deferred to external automation software, rather than a function of TCP/IP. For IPv4 interfaces that are defined with DEVICE and LINK statements, see also the AUTORESTART parameter in [“Overview of DEVICE and LINK statements” on page 35](#). For IPv6 interfaces and IPv4 interfaces that are defined with the INTERFACE statement, the autorestart function is always active.

DYNAMICXCF | NODYNAMICXCF

Indicates XCF support status.

NODYNAMICXCF

Indicates XCF dynamic support is not enabled. The NODYNAMICXCF parameter is confirmed by the message:

```
EZZ0624I DYNAMIC XCF DEFINITIONS ARE DISABLED
```

NODYNAMICXCF is the default value.

DYNAMICXCF

Indicates that dynamic XCF support is enabled for IPv4.

When DYNAMICXCF is coded in the profile, the purpose is to generate dynamic XCF interfaces, if possible. When TCP/IP is active, but ISTLSXCF is not active, dynamic creation is deferred. Later, when a TCP/IP command such as VARY TCPIP,,OBEYFILE or VARY TCPIP,,START is executed, triggering profile processing, the stack again checks to see if ISTLSXCF is active. If ISTLSXCF is active at that time, then the dynamic XCF interfaces are generated.

Dynamic XCF definitions are not generated if there is a DEVICE and LINK definition with the same device or link name that dynamic XCF would generate, or if there is an INTERFACE definition with the same interface name that dynamic XCF would generate.

Activation of dynamic XCF interfaces is delayed if VTAM is not up or if OMPROUTE is not up and DELAYJOIN is coded on the GLOBALCONFIG SYSPLEXMONITOR statement. For more information about [sysplex problem detection and recovery](#), see [z/OS Communications Server: IP Configuration Guide](#).

When using dynamic XCF for Sysplex configuration, make sure that XCFINIT=YES or XCFINIT=DEFINE is coded in the VTAM start options, or if XCFINIT=NO was specified, ensure that a VARY ACTIVATE command is issued for the ISTLSXCF major node. This ensures that XCF connections between TCP stacks on different VTAM nodes in the sysplex can be established. See [z/OS Communications Server: SNA Resource Definition Reference](#) for directions to code the XCFINIT VTAM start option. The DISPLAY NET,VTAMOPTS command can be used to determine the XCFINIT setting.

ipv4_address

The IP address to be used as the home address for all dynamically generated XCF, Same Host, and HiperSockets interfaces. A multicast address is not accepted in this case.

subnet_mask

Specifies the interface-level subnet mask for the DYNAMICXCF interface. If using OMPROUTE, the *subnet_mask* value is overridden with a corresponding OMPROUTE interface parameter value that can be coded or set to the default value.

/num_mask_bits

It is an integer value in the range 1 - 32 that represents the number of leftmost significant bits for the address mask.

cost_metric

Specifies the interface-level metric for the cost of use for the DYNAMICXCF interface. The *cost_metric* value is an integer in the range 0 - 14. If using OMPROUTE, the *cost_metric* value is overridden with a corresponding OMPROUTE interface parameter value that can be coded or set to the default value (Cost0= on OSPF_INTERFACE or In_Metric= on RIP_INTERFACE).

SECCLASS security_class

Use this parameter to associate a security class for IP filtering with each dynamic XCF interface. In order for traffic over the interface to match a filter rule, the filter rule must have the same security class value as the interface or a value of 0. Filter rules can be specified in the TCP/IP profile or in an IP Security policy file read by the Policy Agent. Filter rules can include a security class specification on the IpService statement in an IP Security policy file or on the SECCLASS parameter on the IPSEC statement in the TCP/IP profile.

Valid security classes are identified as a number in the range 1 - 255. The default value is 255. For more information about [security class values](#), see [z/OS Communications Server: IP Configuration Guide](#).

This value is used only when IPSECURITY is specified on the IPCONFIG statement.

SMCD | NOSMCD

Specifies whether the dynamically generated XCF HiperSockets interface can be used for new TCP connections with Shared Memory Communications - Direct Memory Access (SMC-D).

SMCD

Specifies that the dynamically generated XCF HiperSockets interface can be used for new TCP connections with SMC-D. This is the default setting.

NOSMCD

Specifies that the dynamically generated XCF HiperSockets interface cannot be used for new TCP connections with SMC-D.

Rule: SMCD has no effect unless a nonzero subnet mask is configured on the DYNAMICXCF statement.

SOURCEVIPINTERFACE vipa_name

The SOURCEVIPINTERFACE parameter is optional. This parameter specifies which static VIPA interface is to be used as the source IP address when IPCONFIG SOURCEVIPA is specified and outbound packets are sent over the dynamically generated XCF, Same Host, or HiperSockets interfaces. The *vipa_name* value is the interface name for a VIRTUAL interface. The maximum length is 16 characters.

The use of the SOURCEVIPINTERFACE parameter can be overridden. See [source IP selection](#) in [z/OS Communications Server: IP Configuration Guide](#) for the hierarchy of ways that the source IP address of an outbound packet is determined.

Requirement: The VTAM ISTLSXCF major node must be active for XCF dynamics to work, except for the following scenarios:

- Multiple TCP/IP stacks on the same MVS image; a dynamic samehost definition is generated whether ISTLSXCF is active or not.
- HiperSockets is configured and enabled across multiple z/OS systems that are in the same sysplex and the same CEC; a dynamic IUTIQDIO link is created whether ISTLSXCF is active or not.

For information about activating the ISTLSXCF major node, see [z/OS Communications Server: SNA Resource Definition Reference](#).

Restriction: A mix of static and dynamic IPv4 and IPv6 definitions for a device are not allowed. For example, if a static IUTSAMEH IPv4 interface is defined, then the IPv6 dynamic definition for IUTSAMEH is not created. If a static IUTSAMEH IPv6 interface is defined, then the IPv4 dynamic definition for IUTSAMEH is not created. The same logic is also applied for XCF interfaces; a mix of static and dynamic IPv4 and IPv6 definitions is not allowed for an XCF interface.

Guidelines:

1. Dynamic XCF can be enabled even in a single system sysplex. HiperSockets can be used between LPARs on the same central processor complex (CPC) even when MVS images in those LPARs are not defined to be part of the same sysplex. HiperSockets can also be used between LPARs even when some of those other LPARs are running Linux, as long as all of the stacks connecting to HiperSockets and needing to exchange IP packets with each other define IP addresses that are all in the same subnet (as defined by the dynamic XCF IP address and subnet mask in the IPCONFIG DYNAMICXCF profile statement).
2. If the DYNAMICXCF parameter is added (using a VARY TCPIP,,OBEYFILE command data set) after the TCP/IP stack and OMPROUTE are active, the DYNAMICXCF link should be configured to OMPROUTE prior to issuing the VARY TCPIP,,OBEYFILE command. If you do not do this, the network mask is used as the subnet mask for the interface.

For more details about the use of DYNAMICXCF, see the DYNAMICXCF information in [z/OS Communications Server: IP Configuration Guide](#). The DYNAMICXCF parameter is confirmed by the message:

```
EZZ0624I DYNAMIC XCF DEFINITIONS ARE ENABLED
```

FORMAT

The FORMAT keyword is optional, and there is no default.

The FORMAT keyword is meaningful only for stacks that are not enabled for IPv6. It controls the format of the command output. If FORMAT SHORT is specified and the stack is enabled for IPv6, then an error message is displayed. If the stack is not enabled for IPv6 and the user specified LONG format, the command output is displayed as if it could contain IPv6 addresses. If the stack is not enabled for IPv6 and the user specified SHORT format or did not specify the FORMAT keyword, then the command output is displayed as if it could contain only IPv4 addresses and not the longer IPv6 addresses.

If the stack is enabled for IPv6, then specifying the FORMAT keyword does not make any difference to the command format

IGNOREREDIRECT

Causes TCP/IP to ignore ICMP Redirect packets. The IGNOREREDIRECT parameter is confirmed by the message:

```
EZZ0335I ICMP WILL IGNORE REDIRECTS
```

If you are using OMPROUTE and you have IPv4 interfaces configured to OMPROUTE and this option is not specified, IGNOREREDIRECT is enabled automatically.

If you are using intrusion detection services (IDS) policy to detect and discard ICMP Redirects and this option is not specified, ICMP Redirects are discarded anyway while the policy is active.

If this option is not specified, and an ICMP redirect is received for a destination for which there is a HOST route in the routing table, then the original route is deleted and replaced by the redirect. This applies to all routes, including static routes.

IPSECURITY

Activates IPv4 IP filtering and IPv4 IPsec tunnel support.

Requirements:

- Use this parameter so that the stack can function with the Communications Server IKE daemon, and for the stack to receive IPv4 IPsec policy information such as IP filter rules from the policy agent.
- Use this parameter so that the stack can receive defensive filters from the Defense Manager daemon (DMD).

The IPSECURITY parameter is confirmed by the message:

```
EZZ0753I IPV4 SECURITY SUPPORT IS ENABLED
```

Restriction: IPsec functions can be activated only at initial activation of TCP/IP.

IQDIOROUTING | NOIQDIOROUTING

NOIQDIOROUTING

Specifies that inbound packets that are to be forwarded by this TCP/IP stack should not be routed directly between a HiperSockets device and an OSA device in QDIO mode. These packets are processed and routed by this TCP/IP stack.

NOIQDIOROUTING is the default value. If NOIQDIOROUTING is explicitly specified, then the stack confirms that direct routing is disabled with the following message:

```
EZZ0688I IQDIO ROUTING IS DISABLED
```

IQDIOROUTING

Specifies that inbound packets that are to be forwarded by this TCP/IP stack are eligible to be routed directly between a HiperSockets device and an OSA device in QDIO mode without needing to be sent to this TCP/IP stack for forwarding. This type of routing over a HiperSockets device (iQDIO) is called HiperSockets Accelerator. If specified, HiperSockets Accelerator routes are created dynamically as this TCP/IP stack learns of destination IP addresses that can be routed to or from HiperSockets links without needing to be forwarded to this TCP/IP stack. HiperSockets Accelerator support cannot be enabled if the IPSECURITY parameter or the NODATAGRAMFWD parameter is specified. Use of the IQDIOROUTING parameter is confirmed by the following message:

```
EZZ0688I IQDIO ROUTING IS ENABLED
```

If HiperSockets Accelerator support cannot be enabled, message EZZ0689I is issued with the reason. This message is also issued if IQDIOROUTING is specified in the data set that is used with the VARY TCPIP,,OBEYFILE command, if TCP/IP was activated with NOIQDIOROUTING and NOQDIOACCELERATOR on the initial profile.

Rule: This parameter is ignored if QDIOACCELERATOR is specified.

Restrictions:

- HiperSockets Accelerator support cannot be enabled during VARY TCPIP,,OBEYFILE command processing unless either IQDIOROUTING or QDIOACCELERATOR was specified on the IPCONFIG statement in the initial profile.
- HiperSockets Accelerator does not accelerate packets either from or to interfaces configured with optimized latency mode. For more information about optimized latency mode, see [Optimized latency mode in z/OS Communications Server: IP Configuration Guide](#).
- You cannot enable HiperSockets accelerator support if you specify the NODATAGRAMFWD parameter.
- You cannot enable HiperSockets accelerator support if you specify the IPSECURITY parameter.

QDIOPRIORITY priority

If traffic is being routed by way of HiperSockets Accelerator, the data is sent using the priority level specified by *priority*. *priority* values are in the range 1 - 4. The default is to send data using priority level 1. See the OSA documentation in [z/OS Communications Server: SNA Network Implementation Guide](#).

QDIOACCELERATOR | NOQDIOACCELERATOR

NOQDIOACCELERATOR

Specifies that inbound packets that are to be forwarded by this TCP/IP stack should not be routed directly between any of the following combinations of interface types:

- A HiperSockets interface and an OSA QDIO interface
- Two OSA QDIO interfaces
- Two HiperSockets interfaces

These packets are processed and routed by this TCP/IP stack.

NOQDIOACCELERATOR is the default value. If NOQDIOACCELERATOR is explicitly specified, the stack confirms this type of routing with the message:

```
EZZ0817I QDIO ACCELERATOR IS DISABLED
```

QDIOACCELERATOR

Specifies that inbound packets that are to be forwarded by this TCP/IP stack are eligible to be routed directly between any of the following combinations of interface types:

- A HiperSockets interface and an OSA QDIO interface
- Two OSA QDIO interfaces
- Two HiperSockets interfaces

These packets do not need to be sent to this TCP/IP stack for forwarding. This also applies to packets that would be forwarded by the Sysplex Distributor. This type of routing is called QDIO Accelerator. See the information about [QDIO Accelerator](#) in [z/OS Communications Server: IP Configuration Guide](#) for more details on this function.

Use of the QDIOACCELERATOR parameter is confirmed by one of the following messages:

```
EZZ0817I QDIO ACCELERATOR IS ENABLED
EZZ0819I QDIO ACCELERATOR IS ENABLED FOR SYSPLEX DISTRIBUTOR ONLY
EZD2020A QDIO ACCELERATOR IS ENABLED ONLY FOR SYSPLEX DISTRIBUTOR BECAUSE OF TCPIP PROFILE FILTER
RULES
EZD2021A QDIO ACCELERATOR IS ENABLED ONLY FOR SYSPLEX DISTRIBUTOR BECAUSE OF POLICY FILTER RULES
EZD2022A QDIO ACCELERATOR IS ENABLED ONLY FOR SYSPLEX DISTRIBUTOR BECAUSE OF DEFENSIVE FILTER RULES
EZD2023I QDIO ACCELERATOR IS ENABLED WITH CURRENTLY INSTALLED IP FILTER RULES
```

You receive the following message with the appropriate reason if QDIO Accelerator support cannot be enabled. You also receive this message if QDIOACCELERATOR is specified in the data set used with the VARY TCPIP,,OBEYFILE command, if TCP/IP was activated with NOIQDIOROUTING and NOQDIOACCELERATOR on the initial profile.

```
EZZ0818I CANNOT ENABLE QDIO ACCELERATOR - reason
```

Rule: IQDIOROUTING is ignored if QDIOACCELERATOR is specified.

Restrictions:

- If you specify the NODATAGRAMFWD parameter, then QDIO Accelerator applies only to packets that are forwarded by the Sysplex Distributor.
- If you specify the IPSECURITY parameter, TCP/IP monitors your IP filter rules and defensive filter rules that apply to routed traffic. Depending on your filter configuration, QDIO Accelerator might be restricted to only packets that are forwarded by the Sysplex Distributor. For more information about QDIO Accelerator and IPSECURITY, see [Search orders used in the native MVS environment](#) in [z/OS Communications Server: IP Configuration Guide](#).
- QDIO Accelerator support cannot be enabled during VARY TCPIP,,OBEYFILE command processing unless either QDIOACCELERATOR or IQDIOROUTING was specified on the IPCONFIG statement in the initial profile.
- QDIO Accelerator does not accelerate packets either from or to interfaces configured with optimized latency mode. For more information about optimized latency mode, see [Optimized latency mode](#) in [z/OS Communications Server: IP Configuration Guide](#).

QDIOPRIORITY *priority*

Specifies that traffic routed by QDIO Accelerator to an OSA interface be sent using the priority level specified by the *priority* value. The priority level can be in range 1 - 4. The default is to send data using priority level 1. See the [OSA-Express feature](#) in the [z/OS Communications Server: SNA Network Implementation Guide](#).

MULTIPATH | NOMULTIPATH

NOMULTIPATH

Disables the multipath routing selection algorithm for outbound IP traffic. If there are multiple equal-cost routes to a destination and NOMULTIPATH is specified, TCP/IP uses the first active route found to send each IP packet. The NOMULTIPATH parameter is confirmed by the message:

```
EZZ0615I MULTIPATH SUPPORT IS DISABLED
```

This is the default value.

Rule: The NOMULTIPATH parameter applies to outbound IP traffic that is routed by using the main route table. This parameter applies also to outbound IP traffic that is routed by using a policy-based route table if the Multipath UseGlobal parameter is specified on the RouteTable statement that defines the policy-based route table. See [“RouteTable statement” on page 1068](#) for more information.

MULTIPATH

Enables the multipath routing selection algorithm for outbound IP traffic. In general, multipath routing provides the routing distribution necessary to balance the network utilization of outbound packets by load splitting. Multipath routing requires multiple equal-cost routes that are either defined statically or added dynamically by routing protocols (except for RIP, which does not provide multipath routing). If MULTIPATH is specified without any subparameters, the default is PERCONNECTION. The MULTIPATH parameter has no effect if there are no multipath routes in the TCP/IP configuration.

Guideline: In some cases, it might appear data is not being equally distributed among each of the equal-cost interfaces. This depends upon the characteristics of the application that is sending or receiving data. For example, when `osnmp walk` is issued, the application initially sends data using a source IP address of `INADDR_ANY`. Subsequently, when the application receives a response, all future sends use the source IP address of the interface where data was just received. The result is that all data is sent out on a single interface, independent of any multipath setting.

Rules:

- The MULTIPATH parameter and its subparameters apply to outbound IP traffic that is routed by using the main route table. This parameter and its subparameters apply also to outbound IP traffic that is routed by using a policy-based route table if the Multipath UseGlobal parameter is specified on the RouteTable statement that defines the policy-based route table. See [“RouteTable statement” on page 1068](#) for more information.
- The multipath routing selection algorithm is applied and can be specified separately for each route table. Specify the algorithm for the main route table by using the MULTIPATH parameter on the IPCONFIG statement. Specify the algorithm for policy-based route tables in the policy definition for each table. See [“RouteTable statement” on page 1068](#) for more information.

Note: The IPCONFIG MULTIPATH|NOMULTIPATH configuration option affects Enterprise Extender (EE) traffic when MULTIPATH=TCPVALUE is coded. For information about [multipath for EE](#) see [z/OS Communications Server: SNA Network Implementation Guide](#). For information about the MULTIPATH start option, see [z/OS Communications Server: SNA Resource Definition Reference](#).

PERCONNECTION

After a round-robin route is selected, connection or connectionless oriented IP packets using the same association always use the same route, as long as that route is active. The MULTIPATH PERCONNECTION parameter is confirmed by the message:

```
EZZ0632I MULTIPATH PERCONNECTION SUPPORT IS ENABLED
```

For more information about EE load balancing and standard logic for a UDP application, see [z/OS Communications Server: SNA Network Implementation Guide](#).

PERPACKET

Connection or connectionless oriented IP packets using the same source and destination address pair do not always use the same route, but do use all possible active routes to that destination host. The MULTIPATH PERPACKET parameter is confirmed by the message:

```
EZZ0632I MULTIPATH PERPACKET SUPPORT IS ENABLED
```

Restrictions:

- Use this option only as an attempt to improve aggregate throughput of IP traffic over multipath routes and for routes for which potentially high CPU consumption in reassembly of out-of-order packets at the receiving end is not an issue. Performance varies according to network configurations used.
- The MULTIPATH PERPACKET parameter cannot be specified if IP security is configured. If both are specified, the following messages are displayed, and multipath routing is disabled:

```
EZZ0763I CANNOT ENABLE IPV4 MULTIPATH PERPACKET SUPPORT WHEN  
IPV4 SECURITY IS ENABLED  
EZZ0615I MULTIPATH SUPPORT IS DISABLED
```

- IP traffic on RSVP-based routes cannot use this option. Instead, the PERCONNECTION option is used for these routes.
- Fragmented and packed IP datagrams cannot use this option. These datagrams are being sent over one selected route to the intended destination.

PATHMTUDISCOVERY | NOPATHMTUDISCOVERY

NOPATHMTUDISCOVERY

Indicates that TCP/IP is not to provide path MTU (PMTU) discovery support. This is the default value. The NOPATHMTUDISCOVERY parameter is confirmed by the message:

```
EZZ0623I PATH MTU DISCOVERY SUPPORT IS DISABLED
```

PATHMTUDISCOVERY

Indicates that TCP/IP is to dynamically discover the PMTU, which is the smallest MTU of all the hops in the path. Use this parameter to prevent fragmentation of datagrams. The PATHMTUDISCOVERY parameter is confirmed by the message:

```
EZZ0623I PATH MTU DISCOVERY SUPPORT IS ENABLED
```

Requirement: PATHMTUDISCOVERY uses ICMP fragmentation-needed errors to detect the PMTU for a path. If you use PATHMTUDISCOVERY, you must permit ICMP errors to flow at all hosts along the path of a connection. PATHMTUDISCOVERY does not function if a firewall blocks ICMP errors.

For a policy-based route table, the IgnorePathMtuUpdate parameter on the Policy Agent RouteTable statement can be used to prevent the path MTU value from being updated for routes in the table. See the information about the IgnorePathMtuUpdate parameter in [“RouteTable statement”](#) on page 1068 for information about determining when you should prevent the path MTU value from being updated for a policy-based route table.

REASSEMBLYTIMEOUT *reassembly_timeout*

The amount of time (in seconds) allowed to receive all parts of a fragmented packet before the fragments received are discarded. The minimum value is 1, the maximum value is 240, and the default is 60.

SEGMENTATIONOFFLOAD | NOSEGMENTATIONOFFLOAD

Specifies whether the stack should offload TCP segmentation for IPv4 packets to OSA features. The TCP segmentation offload support transfers the overhead of segmenting outbound data into individual TCP packets to OSA devices that support this function. Offloading segmentation of streaming-type workloads reduces CPU use and increases throughput. This parameter is ignored for OSA-Express features that do not support segmentation offload. This value overrides the SEGMENTATIONOFFLOAD or NOSEGMENTATIONOFFLOAD parameter specified on the GLOBALCONFIG statement.

See the steps for modifying topic for information about changing this parameter while the TCP/IP stack is active. See [segmentation offload information in z/OS Communications Server: IP Configuration Guide](#) for more information about TCP segmentation offload support.

NOSEGMENTATIONOFFLOAD

TCP segmentation is performed by the TCP/IP stack. This value is the default value.

SEGMENTATIONOFFLOAD

TCP segmentation is offloaded to the OSA feature.

SOURCEVIPA | NOSOURCEVIPA

NOSOURCEVIPA

Specifies that TCP/IP is not requested to use the corresponding virtual IP address in the HOME list as the source IP address for outbound datagrams. The NOSOURCEVIPA parameter is confirmed by the message:

```
EZZ0351I SOURCEVIPA SUPPORT IS DISABLED.
```

NOSOURCEVIPA is the default value.

SOURCEVIPA

Requests that TCP/IP use the TCPSTACKSOURCEVIPA address (if specified) or the corresponding virtual IP address in the HOME list as the source IP address for outbound datagrams that do not have an explicit source address. If the outgoing interface was defined with the INTERFACE statement, TCP/IP uses the VIPA specified on the SOURCEVIPAINTERFACE parameter of the INTERFACE statement instead of the HOME list. You must specify the TCPSTACKSOURCEVIPA parameter, update the HOME statement, or use the SOURCEVIPAINTERFACE parameter of the INTERFACE statement for the SOURCEVIPA parameter to take effect. For more information about how the order of the HOME list impacts source VIPA selection, see [“HOME statement” on page 76](#). This parameter has no effect on OMPROUTE RIP packets used by RIP services or OSPF packets used by OSPF services. The SOURCEVIPA parameter is confirmed by the following message:

```
EZZ0351I SOURCEVIPA SUPPORT IS ENABLED
```

Tip: You can override the SOURCEVIPA or TCPSTACKSOURCEVIPA values. See the information about [source IP selection in z/OS Communications Server: IP Configuration Guide](#) for the hierarchy of ways that the source IP address of an outbound packet is determined.

SYSPLEXROUTING | NOSYSPLEXROUTING

NOSYSPLEXRouting

Specifies that this TCP/IP host is not part of an MVS sysplex domain. Use of the NOSYSPLEXROUTING parameter is confirmed by the message:

```
EZZ0350I SYSPLEX ROUTING SUPPORT IS DISABLED
```

NOSYSPLEXROUTING is the default value.

SYSPLEXRouting

Specifies that this TCP/IP host is part of an MVS sysplex domain. The SYSPLEXROUTING parameter is confirmed by the message:

```
EZZ0350I SYSPLEX ROUTING SUPPORT IS ENABLED
```

TCPSTACKSOURCEVIPA | NOTCPSTACKSOURCEVIPA

NOTCPSTACKSOURCEVIPA

Specifies that TCP/IP does not use a stack-level IP address as the source address for outbound TCP connections. The source IP address is governed by the IPCONFIG SOURCEVIPA setting.

TCPSTACKSOURCEVIPA *vipa_addr*

The IPv4 address (*vipa_addr*) is used as the source IP address for outbound TCP connections if SOURCEVIPA has been enabled. The *vipa_addr* value must be a static VIPA or an active dynamic VIPA (DVIPA).

If SOURCEVIPA has not been enabled, TCPSTACKSOURCEVIPA is ignored, and the following message is issued:

```
EZZ0706I TCPSTACKSOURCEVIPA IS IGNORED - SOURCEVIPA IS NOT ENABLED
```

Restriction: At the time of an outbound TCP request, the TCPSTACKSOURCEVIPA address must be a static VIPA or active dynamic VIPA, or it is not used for the source IP address. For a static VIPA, it must be defined on DEVICE/LINK statement and not an INTERFACE statement that can have the equivalent SOURCEVIPAINTERFACE parameter. A DEVICE/LINK/HOME statement is generated for a dynamic VIPA.

Tips:

- After it is set, TCPSTACKSOURCEVIPA is not disabled until a profile explicitly adds NOTTCPSTACKSOURCEVIPA to the IPCONFIG statement.
- If you specify the same distributed DVIPA interface for TCPSTACKSOURCEVIPA on multiple target stacks, you also should specify SYSPLEXPORTS on the VIPADISTRIBUTE statement. Otherwise connections might be disrupted because identical connections could be created from more than one stack.
- Carefully consider the following condition when determining the interface to use for TCPSTACKSOURCEVIPA. A dynamic VIPA that becomes inactive because it moves to another TCP/IP stack, or that is deleted because the application that caused its creation (in the case of a VIPARANGE created address) causes its deletion, is no longer a valid interface for TCPSTACKSOURCEVIPA.
- The use of TCPSTACKSOURCEVIPA can be overridden. See the information about [source IP selection](#) in *z/OS Communications Server: IP Configuration Guide* for the hierarchy of ways that the source IP address of an outbound packet is determined.
- TCPSTACKSOURCEVIPA is not used by the stack that owns the DVIPA when an outbound TCP request is connecting to a DVIPA that is active in the Home list.

TTL *time_to_live*

Number of hops that packets originating from this host can travel before reaching the destination. If the destination is more hops away, the packet never reaches the destination. The minimum value is 1, the maximum value is 255, and the default is 64.

Steps for modifying

To modify most parameters for the IPCONFIG statement, you must respecify the statement with the new parameters. Additional actions are required to modify the following parameters:

CHECKSUMOFFLOAD | NOCHECKSUMOFFLOAD

If the CHECKSUMOFFLOAD or NOCHECKSUMOFFLOAD parameter is changed with the VARY TCPIP,,OBEYFILE command, the new value does not affect any active OSA interfaces. For this change to affect an active OSA interface, the interface must be stopped and restarted.

DYNAMICXCF

If dynamic XCF definitions have been enabled but a later VARY TCPIP,,OBEYFILE command contains NODYNAMICXCF, only future dynamic definitions and connectivity are affected. Existing definitions and connectivity are not affected.

After support is enabled, none of the parameters specified on the IPCONFIG DYNAMICXCF statement can be changed with a VARY TCPIP,,OBEYFILE command. You must first stop the TCP/IP stack, apply changes, and then restart the TCP/IP stack.

IPSECURITY

z/OS IPsec functions cannot be activated using VARY TCPIP,,OBEYFILE on an active TCP/IP stack. To activate z/OS IPsec, halt all traffic on the designated TCP/IP stack, stop the stack, modify the TCP profile to include IPCONFIG IPSECURITY, and restart the stack.

IQDIOROUTING

If HiperSockets Accelerator is active then:

- You can disable HiperSockets Accelerator by issuing the VARY TCPIP,,OBEYFILE command and specifying IPCONFIG NOIQDIOROUTING.
- You can activate QDIO Accelerator by issuing the VARY TCPIP,,OBEYFILE command and specifying IPCONFIG NOIQDIOROUTING QDIOACCELERATOR.

If HiperSockets Accelerator and QDIO Accelerator are not active and you want to enable HiperSockets Accelerator, enable HiperSockets Accelerator by issuing the VARY TCPIP,,OBEYFILE command and specifying IPCONFIG IQDIOROUTING (if either IQDIOROUTING or QDIOACCELERATOR was specified in the initial profile); otherwise, stop the stack, modify the profile to include IPCONFIG IQDIOROUTING and restart the stack.

NODATAGRAMFWD

If HiperSockets Accelerator is enabled and IP forwarding is subsequently disabled by issuing a VARY TCPIP,,OBEYFILE with NODATAGRAMFWD specified, HiperSockets Accelerator is also disabled. If HiperSockets Accelerator is disabled, and IPCONFIG IQDIOROUTING is subsequently specified on a VARY TCPIP,,OBEYFILE command for an active TCP/IP stack where IP Forwarding is disabled, HiperSockets Accelerator remains disabled.

If QDIO Accelerator is enabled and IP Forwarding is subsequently disabled using NODATAGRAMFWD in a VARY TCPIP,,OBEYFILE command data set, QDIO Accelerator remains enabled but only for Sysplex Distributor forwarding. If QDIO Accelerator is disabled and IPCONFIG QDIOACCELERATOR is subsequently specified on a VARY TCPIP,,OBEYFILE command for an active TCP/IP stack on which IP forwarding is disabled, QDIO Accelerator is enabled for Sysplex Distributor forwarding only.

QDIOACCELERATOR

If QDIO Accelerator is active:

- You can disable QDIO Accelerator by issuing the VARY TCPIP,,OBEYFILE command and specifying IPCONFIG NOQDIOACCELERATOR.
- You can activate HiperSockets Accelerator by issuing the VARY TCPIP,,OBEYFILE command and specifying IPCONFIG NOQDIOACCELERATOR IQDIOROUTING.

If QDIO Accelerator and HiperSockets Accelerator are not active and you want to enable QDIO Accelerator, enable QDIO Accelerator by issuing the VARY TCPIP,,OBEYFILE command and specifying IPCONFIG QDIOACCELERATOR (if either IQDIOROUTING or QDIOACCELERATOR was specified in the initial profile); otherwise, stop the stack, modify the profile to include IPCONFIG QDIOACCELERATOR and restart the stack.

MULTIPATH

If you modify the multipath routing type (PERCONNECTION to PERPACKET, or vice versa), the new parameter takes effect only for new connections created after the modification is done, and existing connections use whatever the value was when the connection was established. If you enable multipath routing when it was previously disabled, existing connections are not affected; multipath routing is applied only to new connections.

SEGMENTATIONOFFLOAD | NOSEGMENTATIONOFFLOAD

If the SEGMENTATIONOFFLOAD or NOSEGMENTATIONOFFLOAD parameter is changed with the VARY TCPIP,,OBEYFILE command, the new value does not affect any active OSA interfaces. For this change to affect an active OSA interface, the interface must be stopped and restarted.

Examples

```
IPCONFIG NODATAGR  
DYNAMICXCF 9.9.9.9 255.255.255.0 15
```

This example shows an IPCONFIG statement that does the following tasks:

- Disables IP forwarding

- Enables dynamic XCF support and indicates that 9.9.9.9 is the IP address to be used as the home address for all dynamically generated XCF, Same Host, and HiperSockets links. These links have an interface-level subnet mask of 255.255.255.0 and a metric of 15.

Usage notes

- If the stack is enabled for IPv6 and the user specified LONG format, the command output is displayed in IPv6 format.
- The FORMAT keyword is meaningful only for stacks that are not enabled for IPv6. It controls the format of the command output. If FORMAT SHORT is specified and the stack is enabled for IPv6, then the following error message is displayed:

```
EZZ0687I FORMAT SHORT IGNORED - IPV6 SUPPORT IS ENABLED
```

- If you do not include any configuration data in the OMPROUTE configuration file for the XCF links, OMPROUTE does not communicate a routing protocol (OSPF or RIP) over the interfaces. OMPROUTE includes (in the data sent to other routers) information relative to the XCF links as long as Send_Static_Routes=YES is configured for RIP Interfaces and AS_Boundary_Routing(Import_Static_Routes=YES) is configured for OSPF.

Rule: If you want to communicate the OSPF or RIP protocol over a subset of the XCF links, you must configure the appropriate links in the OMPROUTE configuration file using the OSPF_Interface or RIP_Interface statements. Doing this enables OMPROUTE to communicate to other routers not only the information relative to the XCF links, but also information relative to resources on the other side of the host at the opposite end of the XCF links.

To configure the appropriate links, you can explicitly configure each XCF link as either an OSPF or RIP interface (including those that might become active in the future). Alternatively, you can use the wildcard configuration capability of OMPROUTE to configure your XCF links.

To use the wildcard configuration, use a wildcard address (for example, 9.67.100.*) on the OSPF_Interface or RIP_Interface statement instead of an explicit address. In this way, any interface address falling within that wildcard range (9.67.100.1, 9.67.100.2, and so on) is configured using the parameters specified on the wildcard definition statement.

When adding links, XCF or otherwise, to both OMPROUTE and TCP/IP, it is necessary to add them to OMPROUTE before adding them to TCP/IP for proper routing protocol configuration.

Related topics

- [“GLOBALCONFIG statement” on page 49](#)
- [“IPCONFIG6 statement” on page 156](#)
- [“SRCIP statement” on page 233](#)

IPCONFIG6 statement

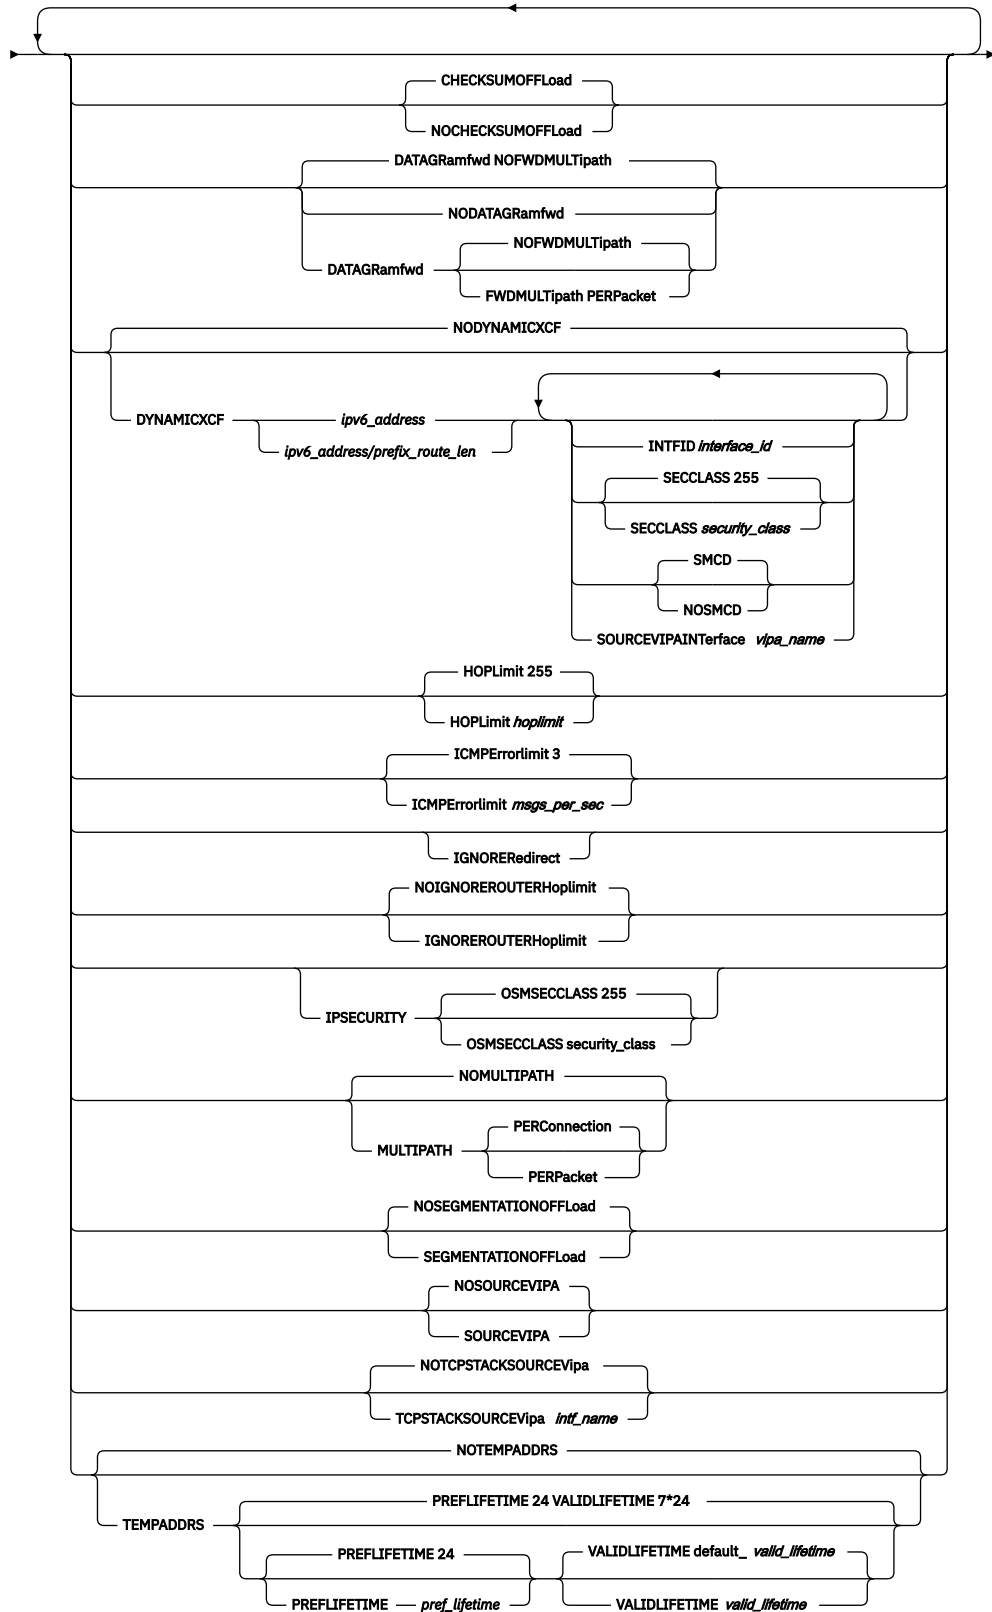

Use the IPCONFIG6 statement to update the IP layer of TCP/IP with information that pertains to IPv6.

If the stack is not configured for IPv6 and IPCONFIG6 is specified, the following error message is generated, and TCP/IP startup processing continues.

```
EZZ0695I IPCONFIG6 NOT VALID - IPV6 SUPPORT IS NOT ENABLED
```

Syntax

Tip: Specify the parameters for this statement in any order.

Parameters

CHECKSUMOFFLOAD | NOCHECKSUMOFFLOAD

Specifies whether the stack should offload inbound and outbound checksum processing (TCP and UDP checksums) for IPv6 packets to OSA features. The checksum offload support transfers the overhead of most checksum processing to OSA devices that support this function. Offloading checksum processing reduces CPU use and increases throughput.

See “Steps for modifying” on page 166 for information about changing this parameter while the TCP/IP stack is active. See Checksum offload in *z/OS Communications Server: IP Configuration Guide* for more information about the checksum offload support and for specific information about which packets can have checksum processing performed by the OSA.

NOCHECKSUMOFFLOAD

Checksum processing is performed by the TCP/IP stack.

CHECKSUMOFFLOAD

Checksum processing is offloaded to the OSA feature. This value is the default value.

DATAGRAMFWD | NODATAGRAMFWD

NODATAGRAMFWD

Disables the forwarding of IP packets that are received by, but not addressed to, the stack. This statement can be used for security or to ensure correct usage of limited resources. The NODATAGRAMFWD parameter is confirmed by the message:

```
EZZ0699I IPV6 FORWARDING IS DISABLED
```

If the TCP/IP stack is also configured to be a sysplex distributor (see “VIPADYNAMIC statement summary” on page 253 for more information), datagrams destined to a sysplex-distributed dynamic VIPA are forwarded to stacks, whether or not forwarding is enabled.

DATAGRAMFWD

Enables the forwarding of IP packets that are received by, but not addressed to, the stack. This is the default value.

NOFWMULTIPATH

When forwarding is in effect and there are multiple equal-cost routes to the destination and the NOFWMULTIPATH parameter is specified, TCP/IP uses the first active route found for forwarding each IP packet. This is the default value. The DATAGRAMFWD NOFWMULTIPATH parameter is confirmed by the message:

```
EZZ0700I IPV6 FORWARDING NOFWMULTIPATH SUPPORT IS ENABLED
```

FWMULTIPATH PERPACKET

When forwarding is in effect and there are multiple equal-cost routes to the destination and the FWMULTIPATH PERPACKET parameter is specified, TCP/IP selects a route for forwarding each IP packet on an approximate round-robin basis from the multiple equal-cost routes. Connection or connectionless-oriented IP packets using the same destination address do not always use the same route, but they do use all possible active routes to that destination host. All IP packets for a given association with a destination host are spread across the multiple equal-cost routes. The DATAGRAMFWD FWMULTIPATH PERPACKET parameter is confirmed by the message:

```
EZZ0700I IPV6 FORWARDING FWMULTIPATH PERPACKET SUPPORT IS ENABLED
```

DYNAMICXCF | NODYNAMICXCF

NODYNAMICXCF

Indicates XCF dynamic support is not enabled for IPv6 on this TCP/IP. The NODYNAMICXCF parameter for IPCONFIG6 is confirmed by the message:

```
EZZ0739I IPV6 DYNAMIC XCF DEFINITIONS ARE DISABLED
```

DYNAMICXCF

Indicates that dynamic XCF support is enabled for IPv6.

When DYNAMICXCF is coded in the profile, the purpose is to generate those dynamic XCF devices or interfaces, if possible. When TCP/IP is up, but ISTLSXCF is not active, dynamic creation is deferred. Later, when a TCP/IP command such as VARY TCPIP,,OBEYFILE or VARY TCPIP,,START is executed, triggering profile processing, the stack again checks to see if ISTLSXCF is active. If ISTLSXCF is active at that time, then the dynamic XCF devices and interfaces are generated.

Dynamic XCF definitions are not generated if there is a DEVICE or INTERFACE definition with the same device or interface name that dynamic XCF would generate.

Activation of dynamic XCF links is delayed if VTAM is not up or if OMPROUTE is not up and DELAYJOIN is coded on the GLOBALCONFIG SYSPLEXMONITOR statement. For more information about [sysplex problem detection and recovery](#), see [z/OS Communications Server: IP Configuration Guide](#).

When using dynamic XCF for sysplex configuration, make sure that XCFINIT=YES or XCFINIT=DEFINE is coded in the VTAM start options, or if XCFINIT=NO was specified, ensure that a VARY ACTIVATE command is issued for the ISTLSXCF major node. This ensures that XCF connections between TCP stacks on different VTAM nodes in the sysplex can be established. See [z/OS Communications Server: SNA Resource Definition Reference](#) for directions for coding the XCFINIT VTAM start option. The DISPLAY NET,VTAMOPTS command can be used to determine the XCFINIT setting.

The VTAM ISTLSXCF major node must be active for XCF dynamics to work, except for the following two scenarios:

- Multiple TCP/IP stacks on the same MVS image; a dynamic samehost definition is generated, whether ISTLSXCF is active or not.
- HiperSockets is configured and enabled across multiple z/OS systems that are in the same sysplex and the same CEC; a dynamic IUTIQDIO link is created, whether ISTLSXCF is active or not.

For information about activating the ISTLSXCF major node, see [z/OS Communications Server: SNA Resource Definition Reference](#).

Dynamic XCF can be enabled even in a single system sysplex. HiperSockets can be used between LPARs on the same central processor complex (CPC) even when MVS images in those LPARs are not defined to be part of the same sysplex. HiperSockets can also be used between LPARs even when some of those other LPARs are running Linux, as long as all of the stacks connecting to HiperSockets and needing to exchange IP packets with each other define IP addresses that are all in the same subnet (as defined by the dynamic XCF IP address and subnet mask in the IPCONFIG6 DYNAMICXCF profile statement).

A mix of static and dynamic IPv4 and IPv6 definitions for a device are not allowed. For example, if a static IUTSAMEH IPv4 device/link is defined, then the IPv6 dynamic definition for IUTSAMEH is not created. If a static IUTSAMEH IPv6 interface is defined, then the IPv4 dynamic definition for IUTSAMEH is not created. The same logic is also applied for XCF links; a mix of static and dynamic IPv4 and IPv6 definitions is not allowed for an XCF link.

ipv6_address

The fully qualified IPv6 address that is used for all dynamically generated XCF, Same Host, and HiperSockets interfaces.

See [“Restrictions on IPv6 addresses configured in the TCP/IP profile”](#) on page 83 for a list of restrictions that must be observed when specifying this parameter.

prefix_route_len

The length of the routing prefix (an integer value in the range 1 - 128). If specified, and if DYNAMICXCF generates a HiperSockets interface definition, TCP/IP creates a prefix route over the HiperSockets interface using the number of bits specified in *prefix_route_len* of the *ipv6_address*. Therefore, you can configure other stacks outside the sysplex for the same

IQD CHPID using IP addresses with the same prefix such that this stack automatically has a route to these other stacks over the HiperSockets interface generated by DYNAMICXCF. If *prefix_route_len* is not specified, then TCP/IP does not create a prefix route over the HiperSockets interface. For interfaces other than HiperSockets which are generated from DYNAMICXCF, the *prefix_route_len* value has no meaning.

Guideline: Configure a *prefix_route_len* to simplify connectivity if you use HiperSockets on the same IQD CHPID for stacks outside the sysplex or if you configure VIPAROUTE statements.

INTFID interface_id

An optional 64-bit interface identifier in colon-hexadecimal format. IPv6 address shorthand notation (for example, the use of :: to indicate multiple groups of 16 bits of zeros) is not allowed when specifying the interface ID. If specified, this interface ID is used to form the link-local address for the interface.

If INTFID is not coded, TCP/IP generates a random value to be used to form the link-local address.

See “[INTERFACE - IPAQENET6 OSA-Express QDIO interfaces statement](#)” on page 116 for an explanation of restrictions that must be observed when manually specifying the INTFID parameter.

SECCLASS security_class

Use this parameter to associate a security class for IP filtering with each IPv6 dynamic XCF interface. In order for traffic over the interface to match a filter rule, the filter rule must have the same security class value as the interface or a value of 0. Filter rules can be specified in the TCP/IP profile or in an IP Security policy file read by the Policy Agent. Filter rules can include a security class specification on the IpService statement in an IP Security policy file or on the SECCLASS parameter on the IPSEC6RULE statement in the TCP/IP profile.

Valid security classes are identified as a number in the range 1 - 255. The default value is 255. For more information about [security class values](#), see [z/OS Communications Server: IP Configuration Guide](#).

Restriction: This value is used only when IPSECURITY is specified on the IPCONFIG6 statement.

SMCD | NOSMCD

Specifies whether the dynamically generated XCF HiperSockets interface can be used for new TCP connections with Shared Memory Communications - Direct Memory Access (SMC-D).

SMCD

Specifies that the dynamically generated XCF HiperSockets interface can be used for new TCP connections with SMC-D. This is the default setting.

NOSMCD

Specifies that the dynamically generated XCF HiperSockets interface cannot be used for new TCP connections with SMC-D.

SOURCEVIPAINTERFACE vipa_name

The SOURCEVIPAINTERFACE parameter is optional. This parameter specifies which static VIPA interface is to be used as the source IP address when IPCONFIG6 SOURCEVIPA is specified and outbound packets are sent over the dynamically generated XCF or Same Host interfaces. The *vipa_name* value is the interface name for a VIRTUAL6 interface. If the VIPA has multiple IP addresses, then the source VIPA address for outbound packets is selected from among these addresses according to the default source address selection algorithm. The maximum length is 16 characters. For more information, see the default source address selection information in [z/OS Communications Server: IPv6 Network and Appl Design Guide](#).

The use of the SOURCEVIPAINTERFACE parameter can be overridden. See the information about source IP address selection in [z/OS Communications Server: IP Configuration Guide](#) for the hierarchy of ways that the source IP address of an outbound packet is determined.

For more details about the use of DYNAMICXCF, see the DYNAMICXCF information in [z/OS Communications Server: IP Configuration Guide](#). The DYNAMICXCF parameter is confirmed by the message:

```
EZZ0739I IPV6 DYNAMIC XCF DEFINITIONS ARE ENABLED
```

HOPLIMIT *hoplimit*

Number of hops a packet originating at this host can travel enroute to the destination. If the destination is more hops away, the packet never reaches the destination. The valid range is between 1 - 255. The default is 255.

ICMPERRORLIMIT *msgs_per_sec*

This parameter controls the rate at which ICMP error messages can be sent to a particular IPv6 destination address. The number specified is messages per second. The default is 3 messages per second, and the valid range is 1 - 20 messages per second. A token bucket algorithm is used to allow bursts of ICMP errors while limiting the long-term rate.

IGNOREREDIRECT

Causes TCP/IP to ignore ICMPv6 Redirect packets. The IGNOREREDIRECT parameter is confirmed by the message:

```
EZZ0701I ICMPV6 REDIRECTS WILL BE IGNORED
```

If you are using OMPROUTE, and IPv6 interfaces are configured to OMPROUTE, and this option is not specified, IGNOREREDIRECT is enabled automatically. If you are using intrusion detection services (IDS) policy to detect and discard ICMPv6 redirect packets and this option is not specified, ICMPv6 redirect packets are discarded while the policy is active.

IGNOREROUTERHOPLIMIT | NOIGNOREROUTERHOPLIMIT

NOIGNOREROUTERHOPLIMIT

NOIGNOREROUTERHOPLIMIT causes TCP/IP to not ignore a hop limit value received in a router advertisement from a router over an IPAQENET6 interface. This results in the configured global hop limit value being overridden by the router advertisement value for all routes using the interface on which the router advertisement was received. This is the default value. The NOIGNOREROUTERHOPLIMIT parameter is confirmed by the message:

```
EZZ0720I ROUTER ADVERTISEMENT HOP LIMIT VALUES WILL NOT BE IGNORED
```

IGNOREROUTERHOPLIMIT

Although you can configure a global hop limit value for the stack (by way of IPCONFIG6 HOPLIMIT), your stack might receive a different hop limit value in a router advertisement from a router, over an IPAQENET6 interface. This results in the configured global hop limit value being overridden by the router advertisement value for all routes using the interface on which the router advertisement was received. IGNOREROUTERHOPLIMIT gives you a way to prevent this, ensuring that your configured value is always used. The IGNOREROUTERHOPLIMIT parameter is confirmed by the message:

```
EZZ0719I ROUTER ADVERTISEMENT HOP LIMIT VALUES WILL BE IGNORED
```

IPSECURITY

Activates IPv6 IP filtering and IPv6 IPsec tunnel support. This parameter requires the IPSECURITY parameter to be configured for IPv4 on the IPCONFIG statement.

Requirements:

- Use this parameter so that the stack can function with the Communications Server IKE daemon and to enable the stack to receive IPv6 IPsec policy information, such as IP filter rules from the policy agent.
- Use this parameter so that the stack can receive IPv6 defensive filters from the Defense Manager daemon (DMD).

The IPSECURITY parameter is confirmed by the message:

Restriction: IPSec functions can be activated only at initial activation of TCP/IP.

OSMSECCLASS *security_class*

Use this parameter to associate a security class for IP filtering with each OSM interface. In order for traffic over the interface to match a filter rule, the filter rule must have the same security class value as the interface or a value of 0. Filter rules can be specified in the TCP/IP profile or in an IP Security policy file read by the Policy Agent. Filter rules can include a security class specification on the IpService statement in an IP Security policy file or on the SECCLASS parameter on the IPSEC6RULE statement in the TCP/IP profile. For more information about OSM interfaces, see the TCP/IP in an intraensemble network section in [z/OS Communications Server: IP Configuration Guide](#).

Valid security classes are identified as a number in the range 1 - 255. The default value is 255. For more information about [security class values](#), see [z/OS Communications Server: IP Configuration Guide](#).

MULTIPATH | NOMULTIPATH

NOMULTIPATH

Disables the multipath routing selection algorithm for outbound IP traffic. If there are multiple equal-cost routes to a destination and NOMULTIPATH is specified, TCP/IP uses the first active route found to send each IP packet. The NOMULTIPATH parameter is confirmed by the message:

```
EZZ0703I IPV6 MULTIPATH SUPPORT IS DISABLED
```

NOMULTIPATH is the default value.

Rule: The NOMULTIPATH parameter applies to outbound IP traffic that is routed by using the main route table. This parameter applies also to outbound IP traffic that is routed by using a policy-based route table if the Multipath6 UseGlobal parameter is specified on the RouteTable statement that defines the policy-based route table. See [“RouteTable statement” on page 1068](#) for more information.

MULTIPATH

Enables the multipath routing selection algorithm for outbound IP traffic. In general, multipath routing provides the routing distribution necessary to balance the network utilization of outbound packets by load splitting. Multipath routing requires the definition of multiple equal-cost routes that are either defined statically or added dynamically by routing protocols (except for RIP, which does not provide multipath routing). If MULTIPATH is specified without any subparameters, the default is PERCONNECTION. The MULTIPATH parameter has no effect if there are no multipath routes in the TCP/IP configuration.

Rules:

- The MULTIPATH parameter and its subparameters apply to outbound IP traffic that is routed by using the main route table. This parameter and its subparameters apply also to outbound IP traffic that is routed by using a policy-based route table if the Multipath6 UseGlobal parameter is specified on the RouteTable statement that defines the policy-based route table. See [“RouteTable statement” on page 1068](#) for more information.
- The multipath routing selection algorithm is applied and can be specified separately for each route table. Specify the algorithm for the main route table using the MULTIPATH parameter on the IPCONFIG6 statement. Specify the algorithm for policy-based route tables in the policy definition for each table. See [“RouteTable statement” on page 1068](#) for more information.

Note: The IPCONFIG6 MULTIPATH|NOMULTIPATH configuration option affects Enterprise Extender (EE) traffic when MULTIPATH=TCPVALUE is coded. For information about multipath for EE, see [z/OS Communications Server: SNA Network Implementation Guide](#). For information about the MULTIPATH start option, see [z/OS Communications Server: SNA Resource Definition Reference](#).

PERCONNECTION

If there are multiple equal-cost routes to a destination and MULTIPATH PERCONNECTION is specified, TCP/IP, upon first sending an IP packet to a given destination, selects a route on a round-robin basis from a multipath routing list to that destination host. The selected route is used to route IP packets for a given connection or connectionless oriented association to that destination host. Connection or connectionless oriented IP packets using the same association always use the same route, as long as that route is active. The MULTIPATH PERCONNECTION parameter is confirmed by the message:

```
EZZ0704I IPV6 MULTIPATH PERCONNECTION SUPPORT IS ENABLED
```

PERPACKET

If there are multiple equal-cost routes to a destination, TCP/IP, upon sending an IP packet in that destination, selects a route on an approximate round-robin basis from a multipath routing list to that destination host. The selected route is used for routing that IP packet. Connection or connectionless oriented IP packets using the same source and destination address pair do not always use the same route, but do use all possible active routes to that destination host. All IP packets for a given association with a destination host are spread across the multiple equal-cost routes. The MULTIPATH PERPACKET parameter is confirmed by the message:

```
EZZ0704I IPV6 MULTIPATH PERPACKET SUPPORT IS ENABLED
```

Restriction: The MULTIPATH PERPACKET parameter cannot be enabled if the IPSECURITY parameter is specified. If both values are specified, the following messages are displayed, and multipath routing is disabled.

```
EZZ0792I CANNOT ENABLE IPV6 MULTIPATH PERPACKET SUPPORT WHEN  
IPV6 SECURITY IS ENABLED  
EZZ0703I IPV6 MULTIPATH SUPPORT IS DISABLED
```

SEGMENTATIONOFFLOAD | NOSEGMENTATIONOFFLOAD

Specifies whether the stack should offload TCP segmentation for IPv6 packets to OSA features. The TCP segmentation offload support transfers the overhead of segmenting outbound data into individual TCP packets to OSA devices that support this function. Offloading segmentation of streaming-type workloads reduces CPU use and increases throughput.

See the steps for modifying topic for information about changing this parameter while the TCP/IP stack is active. See [segmentation offload information in z/OS Communications Server: IP Configuration Guide](#) for more information about the TCP segmentation offload support.

NOSEGMENTATIONOFFLOAD

TCP segmentation is performed by the TCP/IP stack. This value is the default value.

SEGMENTATIONOFFLOAD

TCP segmentation is offloaded to the OSA feature.

SOURCEVIPA | NOSOURCEVIPA

NOSOURCEVIPA

Specifies that TCP/IP is not requested to use a VIPA address as the source IP address for outbound datagrams. The NOSOURCEVIPA parameter is confirmed by the message:

```
EZZ0702I IPV6 SOURCEVIPA SUPPORT IS DISABLED
```

NOSOURCEVIPA is the default value.

SOURCEVIPA

Requests that TCP/IP use a virtual IP address assigned to the TCPSTACKSOURCEVIPA interface (if TCPSTACKSOURCEVIPA is specified) or to the SOURCEVIPAINTERFACE interface as the source address for outbound datagrams that do not have an explicit source address. If multiple addresses are assigned to the TCPSTACKSOURCEVIPA interface or the SOURCEVIPAINTERFACE interface, the source address is selected from among these addresses according to the default

source address selection algorithm. For more information, see the [default source address selection](#) information in [z/OS Communications Server: IPv6 Network and Appl Design Guide](#).

Requirement: You must specify the SOURCEVIPAINTERFACE keyword on the INTERFACE statement for each interface on which you want that SOURCEVIPA to take effect.

The SOURCEVIPA parameter is confirmed by the message:

```
EZZ0702I  IPV6  SOURCEVIPA  SUPPORT  IS  ENABLED
```

Tip: The use of SOURCEVIPA or TCPSTACKSOURCEVIPA can be overridden. See the information about [source IP selection](#) in [z/OS Communications Server: IP Configuration Guide](#) for the hierarchy of ways that the source IP address of an outbound packet is determined.

TCPSTACKSOURCEVIPA | NOTCPSTACKSOURCEVIPA

NOTCPSTACKSOURCEVIPA

Specifies that TCP/IP does not use a stack-level IPv6 address as the source address for outbound TCP connections. The source IP address is determined by the normal default selection.

TCPSTACKSOURCEVIPA *intf_name*

The name of a static VIPA or a dynamic VIPA interface. The maximum length is 16 characters.

If the interface has multiple IP addresses, then the sourcevipa address for outbound packets is selected from among these addresses according to the default source address selection algorithm. For more information, see the [default source address selection](#) information in [z/OS Communications Server: IPv6 Network and Appl Design Guide](#).

If SOURCEVIPA has not been enabled for IPCONFIG6, IPCONFIG6 TCPSTACKSOURCEVIPA is ignored and the following message is issued:

```
EZZ0760I  IPV6  TCPSTACKSOURCEVIPA  IS  IGNORED  -  SOURCEVIPA  IS  NOT  ENABLED
```

Tips:

- After it is set, TCPSTACKSOURCEVIPA is not disabled until a profile explicitly adds NOTCPSTACKSOURCEVIPA to the IPCONFIG6 statement.
- A dynamic VIPA that becomes inactive because it moves to another TCP/IP stack, or that is deleted because the application that caused its creation (in the case of a VIPARANGE statement created address) causes its deletion, is no longer a valid interface for the TCPSTACKSOURCEVIPA parameter.
- If you specify the same distributed DVIPA interface for TCPSTACKSOURCEVIPA on multiple target stacks, you also should specify SYSPLEXPORTS on the VIPADISTRIBUTE statement. Otherwise connections might be disrupted because identical connections could be created from more than one stack.
- Carefully consider the following when determining the interface to use for TCPSTACKSOURCEVIPA.
 - A dynamic VIPA that becomes inactive because it moves to another TCP/IP stack, or that is deleted because the application that caused its creation (in the case of a VIPARANGE statement created address) causes its deletion, is no longer a valid interface for TCPSTACKSOURCEVIPA.
 - A dynamic VIPA interface that is created by a VIPARANGE statement can have multiple dynamic VIPA addresses associated with it. The actual address chosen as the source IP for the outbound connection is not predictable or necessarily meaningful.
- The use of TCPSTACKSOURCEVIPA can be overridden. See the information about [source IP selection](#) in [z/OS Communications Server: IP Configuration Guide](#) for the hierarchy of ways that the source IP address of an outbound packet is determined.

TEMPADDRS | NOTEMPADDRS

NOTEMPADDRS

Specifies that TCP/IP should not generate IPv6 temporary addresses. Use of the NOTEMPADDRS parameter is confirmed by the message:

```
EZZ0821I IPV6 TEMPORARY ADDRESS SUPPORT IS DISABLED
```

NOTEMPADDRS is the default value.

TEMPADDRS

Requests that TCP/IP generate IPv6 temporary addresses for IPAQENET6 and EQENET6 OSA interfaces for which stateless address auto configuration is enabled. Stateless address auto configuration is enabled for an interface if no address or prefix is specified with the IPADDR keyword. See the information about using IPv6 temporary addresses to address privacy concerns in the [z/OS Communications Server: IPv6 Network and Appl Design Guide](#).

Requirement: You must specify the job name of an application in the SRCIP statement block with a value of TEMPADDRS to cause a temporary IPv6 address to be preferred over a public IPv6 address as the source IP address for the application; otherwise, the default source address selection algorithm prefers public IPv6 addresses over temporary addresses. See the information about default source address selection in the [z/OS Communications Server: IPv6 Network and Appl Design Guide](#).

The TEMPADDRS parameter is confirmed by the message:

```
EZZ0816I IPV6 TEMPORARY ADDRESS SUPPORT IS ENABLED
```

PREFLIFETIME *pref_lifetime*

Preferred lifetime for temporary addresses specified in hours. At the expiration of the preferred lifetime, a new temporary address is generated and the existing address is deprecated. Valid values are in the range 1 - 720 hours (30 days). The default is 24 hours (1 day).

Results:

- A temporary address can be deprecated sooner than specified by the *pref_lifetime* value if the preferred lifetime of the prefix that is learned from a router advertisement is less than the *pref_lifetime*.
- A short preferred lifetime results in new temporary addresses being generated more quickly.

VALIDLIFETIME *valid_lifetime*

Valid lifetime for temporary addresses, specified in hours. At the expiration of the valid lifetime, the temporary address is deleted. Valid values are in the range 2 - 2160 hours (90 days). The default is 7 times the preferred lifetime, not to exceed a maximum value of 90 days.

Rules:

- *valid_lifetime* value must be greater than *pref_lifetime* value.
- If PREFLIFETIME is not explicitly configured, the *valid_lifetime* value must be greater than the default value for *pref_lifetime*.

Results:

- A temporary address can be deleted sooner than specified by the *valid_lifetime* value if the valid lifetime of the prefix that is learned from a router advertisement is less than *valid_lifetime*.
- A short valid lifetime results in deprecated temporary addresses being deleted more quickly.

Guideline: Do not specify a small *pref_lifetime* value with a large *valid_lifetime* value. A large number of deprecated temporary addresses can have an impact on storage usage.

VALIDLIFETIME default *valid_lifetime*

Specifies the default valid lifetime for temporary addresses in hours. The default is 7 times the preferred lifetime; you can specify a maximum value of 90 days.

Steps for modifying

To modify most parameters for the IPCONFIG6 statement, you must respecify the statement with the new parameters. Additional actions are required to modify the following parameters:

CHECKSUMOFFLOAD | NOCHECKSUMOFFLOAD

If the CHECKSUMOFFLOAD or NOCHECKSUMOFFLOAD parameter is changed with the VARY TCPIP,,OBEYFILE command, the new value does not affect any active OSA interfaces. For this change to affect an active OSA interface, the interface must be stopped and restarted.

DYNAMICXCF

None of the parameters on the IPCONFIG6 DYNAMICXCF statement can be changed with a VARY TCPIP,,OBEYFILE command. You must first stop the TCP/IP stack, apply changes, and then restart the TCP/IP stack.

If dynamic XCF definitions have been enabled but a later VARY TCPIP,,OBEYFILE command contains NODYNAMICXCF, only future dynamic definitions and connectivity are affected. Existing definitions and connectivity are not affected.

IPSECURITY

z/OS IPv6 IPsec functions cannot be activated using the VARY TCPIP,,OBEYFILE command on an active TCP/IP stack. To activate z/OS IPsec for IPv6, halt all traffic on the designated TCP/IP stack, stop the stack, modify the TCP profile to include IPCONFIG6 IPSECURITY, and restart the stack.

MULTIPATH

If you modify the multipath routing type (PERCONNECTION to PERPACKET, or vice versa), the new parameter takes effect only for new connections created after the modification is done, and existing connections use whatever the value was when the connection was established. If you enable multipath routing when it was previously disabled, existing connections are not affected; multipath routing is applied to new connections only.

SEGMENTATIONOFFLOAD | NOSEGMENTATIONOFFLOAD

If the SEGMENTATIONOFFLOAD or NOSEGMENTATIONOFFLOAD parameter is changed with the VARY TCPIP,,OBEYFILE command, the new value does not affect any active OSA interfaces. For this change to affect an active OSA interface, the interface must be stopped and restarted.

TEMPADDRS

If you disable temporary addresses by changing TEMPADDRS to NOTEMPADDRS using a VARY TCPIP,,OBEYFILE command, all existing IPv6 temporary addresses are deleted. This is disruptive for connections that are using the temporary address.

- [“SRCIP statement” on page 233](#)

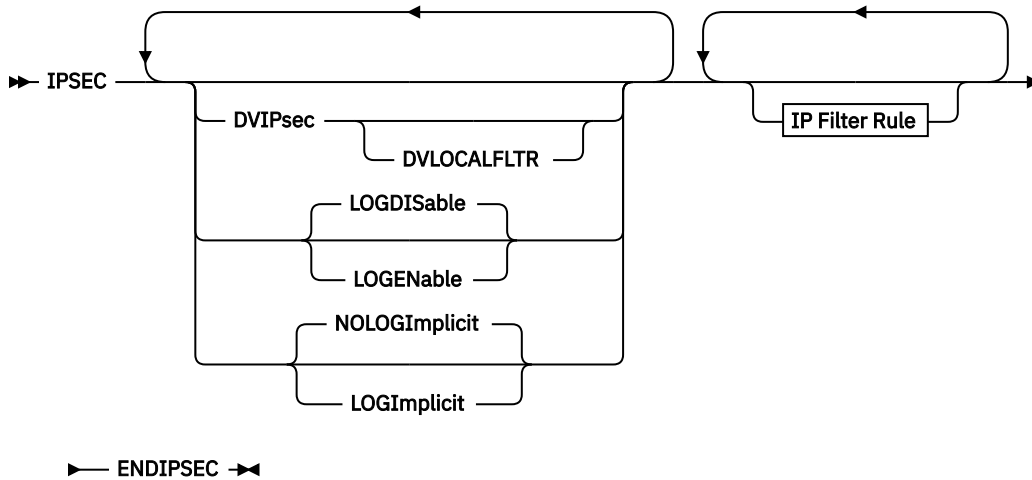

IPSEC statement

Use the IPSEC statement to define policy for the IPv4 security function that is enabled with the IPCONFIG IPSECURITY parameter. The IPSEC statement is ignored if IPSECURITY is not specified on the IPCONFIG statement. If you also enable IPv6 Security with the IPCONFIG6 IPSECURITY parameter, then use the IPSEC statement to also define policy for IPv6 IP security.

Restriction: Only one IPSEC statement block should appear in the profile. Any subsequent statement blocks are ignored and an informational message is generated. Multiple filter rules can be defined in the IPSEC block.

Syntax

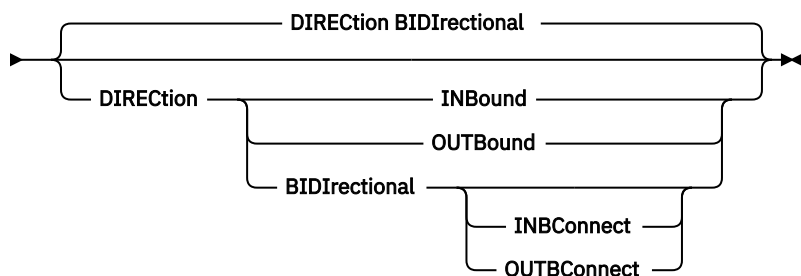

Rule: Specify the parameters in the order shown here.

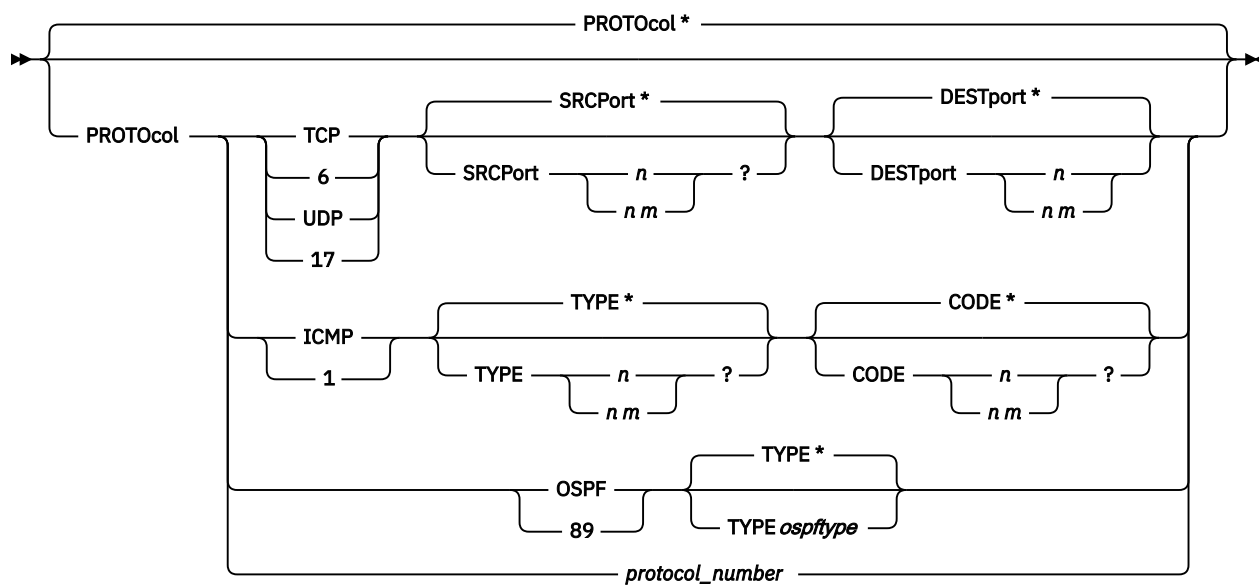

IP Filter Rule

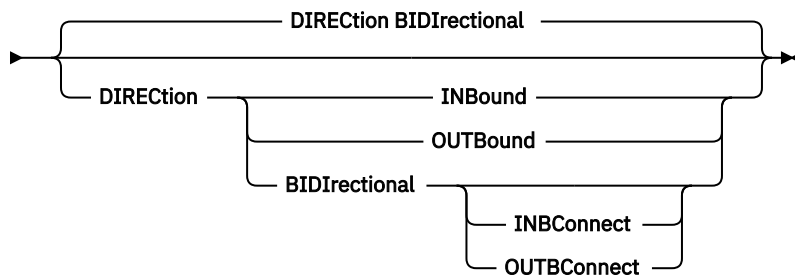

IPv4 Filter Rule

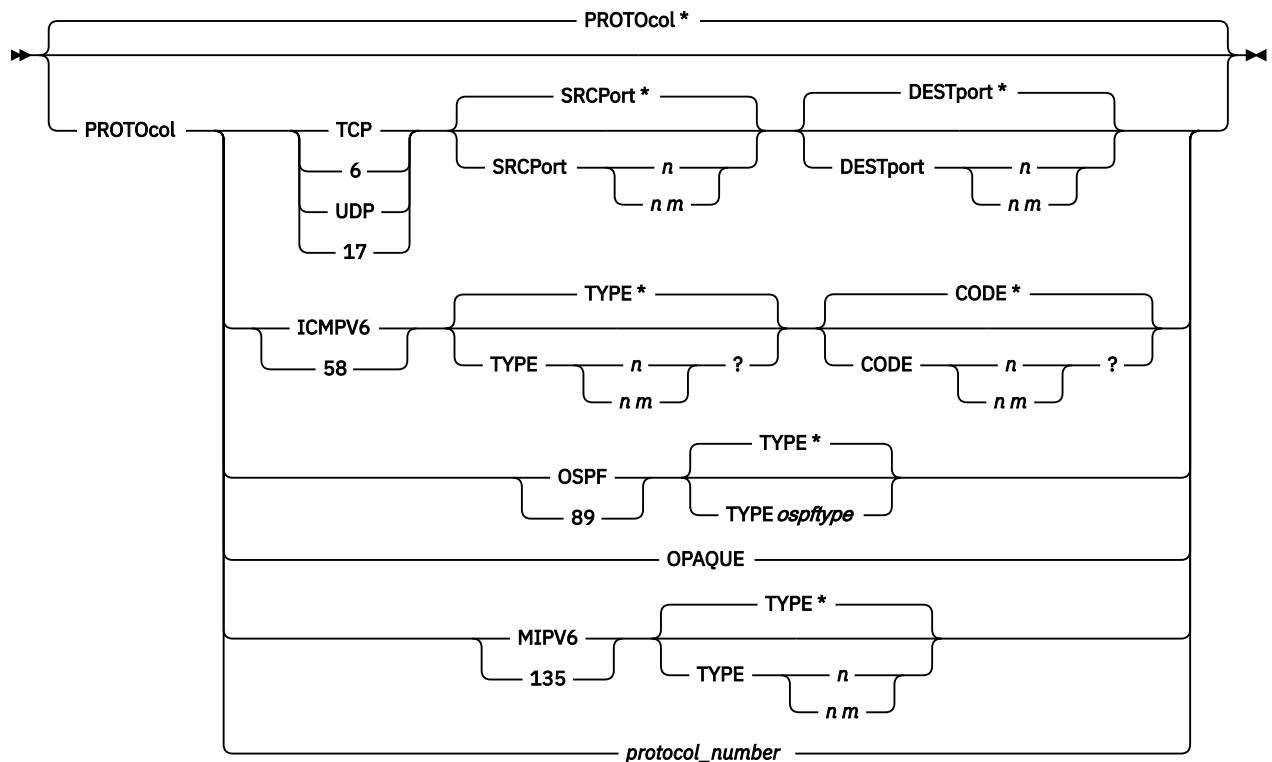

Protocol

IPv6 Filter Rule

Protocol

Parameters

DVIPSEC

Indicates that IPsec tunnels associated with IPv4 and IPv6 dynamic VIPA addresses are eligible to be distributed if the dynamic VIPA address is being distributed. The IPsec tunnels are also eligible to be moved during dynamic VIPA takeover or giveback.

Restrictions:

- The DVIPSEC function can be enabled only in an initial profile. It can not be enabled by using the VARY TCPIP,,OBEYFILE command.
- For tunnels that traverse a NAT device, the dynamic VIPA takeover and giveback function is limited to configurations where IKE can act as initiator. IKE cannot act as initiator in the following configurations:
 - The remote security endpoint is a security gateway and a NAT is being traversed
 - The remote security endpoint is behind an NAPT

For more information about configuration scenarios supported for NAT traversal, see [z/OS Communications Server: IP Configuration Guide](#).

DVLOCALFLTR

Enables IP filtering and IPsec protection of TCP traffic between a client and an IPv4 dynamic VIPA defined on the same TCP/IP stack, when the traffic is forwarded to another TCP/IP stack. By default, IP filtering is not applied to local traffic.

Guidelines: When DVLOCALFLTR is configured to enable IP filtering:

- Ensure that the IPsec policy accounts for all local TCP traffic with an IPv4 dynamic VIPA endpoint. Traffic that does not match a configured IP filter rule is denied.
- Use IKEv2 to negotiate the tunnel to protect the traffic. Use HowToInitiate IKEv2 on the KeyExchangePolicy statement or a specific KeyExchangeAction statement to indicate that IKEv2 should be used when key negotiations are initiated by this system.

Restriction: IKEv1 cannot be used to negotiate a tunnel between a client and an IPv4 dynamic VIPA that are defined on the same TCP/IP stack.

LOGDISABLE/LOGENABLE

Indicates whether packet filter logging is enabled or disabled. The following log messages are controlled by this parameter:

- EZD0814I
- EZD0815I
- EZD0821I
- EZD0832I
- EZD0833I
- EZD0836I
- EZD0822I

If logging is enabled, messages are written to syslogd by the Traffic Regulation Manager Daemon (TRMD).

If LOGENABLE is specified, then the log setting on the individual default filter rules and the implicit default rules is honored. The log setting for individual default rules is specified with the LOG/NOLOG parameter. The log setting for the implicit default rules is specified with the LOGIMPLICIT/NOLOGIMPLICIT parameter.

If LOGDISABLE is specified, then the log setting on the individual default filter rules and the implicit default rules is ignored and no packet filter logging is done.

LOGIMPLICIT/NOLOGIMPLICIT

Indicates whether packet filter logging is enabled or disabled for packets that are denied by the implicit default rules. IP traffic not explicitly permitted by the default IP filter rules parameters described in the following IP Filter Rule parameters topic, is handled by implicit default rules generated by the stack while default IP filter policy is in effect.

If the IPSEC statement is not specified, packet filter logging is disabled for packets that are handled by the implicit default rules. To turn on packet filter logging for the implicit default rules, IPSEC must be coded with the LOGENABLE and LOGIMPLICIT parameters.

A setting of LOGIMPLICIT is honored only when filter logging is enabled on the IPSEC statement with LOGENABLE.

IP Filter Rule parameters

Default IP filter rules can be defined on the IPSEC statement. The default IP filter policy is used prior to the initial loading of IP security policy into the stack from the Policy Agent. It is also used when the IP security policy has been suspended by the z/OS UNIX ipsec command (that is, when the ipsec -f default command is issued).

The default IP filter policy consists of the following rules:

- Rules defined explicitly with the IPSECRULE and IPSEC6RULE statement
- Implicit rules that deny all inbound and outbound data traffic

The explicit rules appear first in the search order and the implicit deny all rules appear last in the search order.

The rules defined explicitly with the IPSECRULE and IPSEC6RULE statements are permit rules. IP traffic not explicitly permitted by one of the defined rules is denied while the default IP filter policy is in effect.

The physical order in which the rules are defined in the profile determines the search order for the rules. The rule parameters are ANDed together to determine whether the IP traffic matches the filter rule.

If you configure an IPSEC6RULE statement but did not specify IPCONFIG6 IPSECURITY, then TCP/IP rejects the IPSEC6RULE statement and issues message EZZ0787I in [z/OS Communications Server: IP Messages Volume 4 \(EZZ, SNM\)](#).

If the IPSEC statement is not specified or if no default IP filter rules are specified, the default IP filter table consists only of the implicitly defined **deny all** rule.

src_ipaddr

A single IP address. If the source address of an IP packet matches this address, the packet is permitted by this rule.

Specify an asterisk (*) to allow any source IP address to match.

Guidelines:

- For IPSECRULE, an asterisk means any IPv4 address. For IPSEC6RULE, an asterisk means any IPv6 address.
- For IPSEC6RULE, the *src_ipaddr* can be any valid IPv6 address in colon-hexadecimal format. IPv4-mapped IPv6 addresses are also allowed.

src_ipaddr/prefix_length

A prefix address specification. If the source address of an IP packet falls within the bounds of this specification, the packet is permitted by this rule. The *prefix_length* is the number of unmasked leading bits in the *ipaddress* value. The *prefix_length* value is in the range 0 - 32 for IPv4 addresses and 0 - 128 for IPv6 addresses. For *prefix_length* values other than zero (0), an IP packet matches this condition if its source address unmasked bits are identical to the defined unmasked bits. Specifying a *prefix_length* value of zero (0) is the same as specifying a *src_ipaddr* value of asterisk (*).

src_ipaddr - src_ipaddr

A range of IP addresses. If the source address of an IP packet falls within this range, inclusive, the packet is permitted by this rule.

Rule: The specification of the IP address range must include blank characters between each IP address and the dash character that separates the beginning and ending range values.

dest_ipaddr

A single IP address. If the destination address of an IP packet matches this address, the packet is permitted by this rule.

Specify an asterisk (*) to allow any destination IP address to match.

Guidelines:

- For IPSECRULE, an asterisk means any IPv4 address. For IPSEC6RULE, an asterisk means any IPv6 address.
- For IPSEC6RULE, the *dest_ipaddr* can be any valid IPv6 address in colon-hexadecimal format. IPv4-mapped IPv6 addresses are also allowed.

dest_ipaddr/prefix_length

A prefix address specification. If the destination address of an IP packet falls within the bounds of this specification, the packet is permitted by this rule. The *prefix_length* is the number of unmasked leading bits in the *ipaddress* value. The *prefix_length* value is in the range 0 - 32 for IPv4 addresses and 0 - 128 for IPv6 addresses. For *prefix_length* values other than zero (0), an IP packet matches this condition if its destination address unmasked bits are identical to the defined unmasked bits. Specifying a *prefix_length* value of zero (0) is the same as specifying a *dest_ipaddr* value of asterisk (*).

dest_ipaddr - dest_ipaddr

A range of IP addresses. If the destination address of an IP packet falls within this range, inclusive, the packet is permitted by this rule.

Rule: The specification of the IP address range must include blank characters between each IP address and the dash character that separates the beginning and ending range values.

LOG/NOLOG

Indicates whether packet filter logging is enabled or disabled for the default filter rule. A setting of LOG is honored only when filter logging is enabled on the IPSEC statement with LOGENABLE.

PROTOCOL

The protocol specification for this rule. For IP traffic to be permitted by this rule, the protocol of the traffic must match this parameter.

Any protocol specification. IP traffic of any protocol can match this rule. This is the default value.

TCP | 6

TCP protocol specification. For IP traffic to be permitted by this rule, the protocol of the traffic must be TCP.

SRCPORT

A TCP source port or range of TCP source ports. For IP traffic to be permitted by this rule, the source port of the traffic must match this parameter.

Valid values are as follows:

Indicates all values in the range 1 - 65535. Any source port matches this parameter value. This is the default.

n

A single value in the range 1 - 65535.

n m

A range of values beginning with *n* and ending with *m*, inclusive, where $n < m$. *n* and *m* values must be in the range 1 - 65535.

Restriction: If the ROUTING value is ROUTED or EITHER, SRCPORT must be defined as all ports (*).

DESTPORT

A TCP destination port or range of TCP destination ports. For IP traffic to be permitted by this rule, the destination port of the traffic must match this parameter.

Valid values are as follows:

Indicates all values in the range 1 - 65535. Any destination port matches this parameter value. This is the default.

n

A single value in the range 1 - 65535.

n m

A range of values beginning with *n* and ending with *m*, inclusive, where $n < m$. *n* and *m* values must be in the range 1 - 65535.

Restriction: If the ROUTING value is ROUTED or EITHER, DESTPORT must be defined as all ports (*).

UDP | 17

UDP protocol specification. For IP traffic to be permitted by this rule, the protocol of the traffic must be UDP.

SRCPORT

A UDP source port or range of UDP source ports. For IP traffic to be permitted by this rule, the source port of the traffic must match this parameter.

Valid values are as follows:

Indicates all values in the range 1 - 65535. Any source port matches this parameter value. This is the default.

n

A single value in the range 1 - 65535.

n m

A range of values beginning with *n* and ending with *m*, inclusive, where $n < m$. *n* and *m* values must be in the range 1 - 65535.

Restriction: If the ROUTING value is ROUTED or EITHER, SRCPORT must be defined as all ports (*).

DESTPORT

A UDP destination port or range of UDP destination ports. For IP traffic to be permitted by this rule, the destination port of the traffic must match this parameter.

Valid values are as follows:

Indicates all values in the range 1 - 65535. Any destination port matches this parameter value. This is the default.

n

A single value in the range 1 - 65535.

n m

A range of values beginning with *n* and ending with *m*, inclusive, where $n < m$. *n* and *m* values must be in the range 1 - 65535.

Restriction: If the ROUTING value is ROUTED or EITHER, DESTPORT must be defined as all ports (*).

ICMP | 1

ICMP protocol specification.

Restriction: The ICMP protocol is valid only on an IPSECRULE statement.

Rule: For IP traffic to be permitted by this rule, the protocol of the traffic must be ICMP.

TYPE

An ICMP type or a range of ICMP types. This parameter is applicable when ICMP is specified for the PROTOCOL parameter.

Valid values are as follows:

Indicates all values in the range 0 - 255. Any ICMP type matches this parameter value. This is the default.

n

A single value in the range 0 - 255.

n m

A range of values beginning with *n* and ending with *m*, inclusive, where $n < m$. *n* and *m* values must be in the range 0 - 255.

Restrictions:

- For IP traffic to be permitted by this rule, the ICMP type of the traffic must match this parameter value.
- If the ROUTING value is ROUTED or EITHER, TYPE must be defined as all types (*).

CODE

An ICMP code or a range of ICMP codes. This parameter is applicable when ICMP is specified for the PROTOCOL parameter.

Valid values are as follows:

Indicates all values in the range 0 - 255. Any ICMP type matches this parameter value. This is the default.

n

A single value in the range 0 - 255.

n m

A range of values beginning with *n* and ending with *m*, inclusive, where $n < m$. *n* and *m* values must be in the range 0 - 255.

Restrictions:

- For IP traffic to be permitted by this rule, the ICMP code of the traffic must match this parameter value.
- If the ROUTING value is ROUTED or EITHER, CODE must be defined as all codes (*).
- If the TYPE value is specified as a range of types, CODE must be defined as all codes (*).

ICMPV6 | 58

ICMPv6 protocol specification.

Restriction: The ICMPv6 protocol is valid only on an IPSEC6RULE statement.

Rule: For IP traffic to be permitted by this rule, the protocol of the traffic must be ICMPv6.

TYPE

An ICMPv6 type or a range of ICMPv6 types. This parameter is applicable when ICMPV6 is specified for PROTOCOL.

Valid values are as follows:

Indicates all values in the range 0 - 255. Any ICMPv6 type matches this parameter value. This is the default.

n

A single value in the range 0 - 255.

n m

A range of values beginning with *n* and ending with *m*, inclusive, where $n < m$. *n* and *m* values must be in the range 0 - 255.

Restrictions:

- For IP traffic to be permitted by this rule, the ICMPv6 type of the traffic must match this parameter value.
- If the ROUTING value is ROUTED or EITHER, TYPE must be defined as all types (*).

CODE

An ICMPv6 code or a range of ICMPv6 codes. This parameter is applicable when ICMPV6 is specified for PROTOCOL.

Valid values are as follows:

Indicates all values in the range 0 - 255. Any ICMPv6 code matches this parameter value. This is the default.

n

A single value in the range 0 - 255.

n m

A range of values beginning with *n* and ending with *m*, inclusive, where $n < m$. *n* and *m* values must be in the range 0 - 255.

Restrictions:

- For IP traffic to be permitted by this rule, the ICMPv6 type of the traffic must match this parameter value.
- If the ROUTING value is ROUTED or EITHER, TYPE must be defined as all types (*).
- If the TYPE value is specified as a range of types, CODE must be defined as all codes (*).

OSPF | 89

OSPF protocol specification.

Restriction: For IP traffic to be permitted by this rule, the protocol of the traffic must be OSPF.

TYPE ospftype

OSPF type. This parameter is applicable when OSPF is specified for PROTOCOL. Valid values are * or 0 - 255.

Restrictions:

- For IP traffic to be permitted by this rule, the OSPF type of the traffic must match this parameter value. The default is *, which indicates that any OSPF type matches.
- If the ROUTING value is ROUTED or EITHER, TYPE must be defined as all types(*).

For a list of the possible IPv4 OSPF types, see RFC 1583 OSPF Version 2. For a list of the possible IPv6 OSPF types, see RFC 2740, OSPF for IPv6. See [Appendix C, “Related protocol specifications,”](#) on page 1349 for more information about accessing RFCs.

OPAQUE

The OPAQUE value matches any IPv6 packet for which the upper-layer protocol is not known as a result of fragmentation. This parameter matches non-initial fragments. It also matches initial fragments if the upper-layer protocol value is not included in the first fragment. The

OPAQUE value is applicable only to routed fragments because for all local traffic, the stack applies IP filter rules only to fully assembled packets.

Restriction: The OPAQUE protocol is valid only on an IPSEC6RULE statement.

MIPv6 | 135

IPv6 mobility protocol specification.

Restriction: The MIPv6 protocol is valid only on an IPSEC6RULE statement.

Rule: For IP traffic to be permitted by this rule, the protocol of the traffic must be MIPv6.

TYPE

A MIPv6 type or a range of MIPv6 types. This parameter is applicable when MIPv6 is specified for PROTOCOL.

Valid values are as follows:

Indicates all values in the range 0 - 255. Any MIPv6 type matches this parameter value. This is the default.

n

A single value in the range 0 - 255.

n m

A range of values beginning with *n* and ending with *m*, inclusive, where $n < m$. *n* and *m* values must be in the range 0 - 255.

Restrictions:

- For IP traffic to be permitted by this rule, the MIPv6 type of the traffic must match this parameter value.
- If the ROUTING value is ROUTED or EITHER, TYPE must be defined as all types (*).

protocol_number

A protocol number in the range 0 - 255.

Restriction: For IP traffic to be permitted by this rule, the protocol of the traffic must match this parameter.

ROUTING

Specifies the type of packet to which this rule applies. Valid values for ROUTING are:

LOCAL

Indicates that this rule applies to packets destined for this stack.

ROUTED

Indicates that this rule applies to packets being forwarded by this stack. When ROUTED is specified, you can further qualify the rule to specify whether the rule applies to only IP packets that are fragmented or all IP packets. If you do not specify FRAGMENTSONLY, the rule applies to all IP packets.

FRAGMENTSONLY

Specifies that the rule applies only to IP packets that are fragmented.

Restriction: The FRAGMENTSONLY parameter is valid only when ROUTING ROUTED is specified.

Tip: Fragments are matched only in routed traffic, because the TCP/IP stack applies IP filter rules for local traffic only to fully reassembled packets.

EITHER

Indicates that this rule applies to forwarded and non-forwarded packets.

The default value is LOCAL.

SECCLASS *security_class*

A security class value in the range 0 - 255.

Restriction: For IP traffic to be permitted by this rule, the security class of the interface that the traffic is inbound to or outbound from must match this parameter.

For IPv4, the security class for the interface is specified as SECCLASS on the LINK, INTERFACE, or IPCONFIG DYNAMICXCF statement. For IPv6, the security class for the interface is specified as SECCLASS on the INTERFACE or IPCONFIG6 DYNAMICXCF statement. A value of 0 matches any security class value coded on the corresponding profile statement which defines the interface. For more information about [security class values](#), see [z/OS Communications Server: IP Configuration Guide](#).

The default value is 0.

DIRECTION

Specifies the direction of a packet to which this rule applies.

OUTBOUND

This value generates one IP filter. The generated rule permits an outbound packet with the specified source and destination.

INBOUND

This value generates one IP filter. The generated rule permits an inbound packet with the specified source and destination.

BIDIRECTIONAL

This value generates two IP filters. The first generated rule permits an outbound packet with the specified source and destination IP address or port. The second generated rule switches the source and destination specification and permits an inbound packet with the switched source and destination specification.

When BIDIRECTIONAL is specified, you can further qualify the rule to indicate the direction of the packet that can generate a TCP connection. You can do so by specifying the INBCONNECT or OUTBCONNECT parameter.

Restriction: INBCONNECT and OUTBCONNECT are honored only for a rule with a PROTOCOL value of TCP.

INBCONNECT

Indicates that a TCP connection can be initiated only by an inbound packet.

OUTBCONNECT

Indicates that a TCP connection can be initiated only by an outbound packet.

Steps for modifying

To modify most parameters for the IPSEC statement, use a VARY TCPIP,,OBEYFILE command with a data set that contains a new IPSEC statement. Additional actions are required to modify the following parameters:

DVIPSEC

The value of DVIPSEC cannot be modified using the VARY TCPIP,,OBEYFILE command on an active TCP/IP stack.

DVLOCALFLTR

The value of DVLOCALFLTR can be modified by using a VARY TCPIP,,OBEYFILE command with a data set that contains a new IPSEC statement, if the DVIPSEC parameter was specified at TCP/IP initialization. To disable the DVLOCALFLTR function, specify the DVIPSEC parameter without the DVLOCALFLTR subparameter. To enable the DVLOCALFLTR function, specify the DVIPSEC parameter with the DVLOCALFLTR subparameter. The current set of IPSECRULE statements must be included in the data set when you are changing the DVLOCALFLTR setting on the IPSEC statement.

If the DVLOCALFLTR setting is changed, traffic for both new and existing connections are affected. Depending on application behavior, an application might have to be recycled for the new DVLOCALFLTR setting to take effect.

LOGDISABLE/LOGENABLE

The value of LOGDISABLE/LOGENABLE can be modified using a VARY TCPIP,,OBEYFILE command with a data set that contains a new IPSEC statement. The current set of IPSECRULE statements should be included in the data set when changing LOGDISABLE/LOGENABLE on the IPSEC statement.

LOGIMPLICIT/NOLOGIMPLICIT

The value of LOGIMPLICIT/NOLOGIMPLICIT can be modified using a VARY TCPIP,,OBEYFILE command with a data set that contains a new IPSEC statement. The current set of IPSECRULE statements should be included in the data set when changing LOGIMPLICIT/NOLOGIMPLICIT on the IPSEC statement.

IP Filter Rules

To modify the default IP filter rules on the IPSEC statement, use a VARY TCPIP,,OBEYFILE command with a data set that contains a new IPSEC statement. All existing default IP filter rules are deleted and replaced with the default IP filter rules defined on the new IPSEC statement.

To delete all defined default filter rules leaving only the implicit deny all default rule, the data set must contain a new IPSEC statement with no default filter rules defined. If the data set does not contain an IPSEC statement, then the existing default filter rules remain in effect.

If IP filtering is being done based on the default filter rules, then the modified default filter rules are in effect following the VARY TCPIP,,OBEYFILE command. If IP filtering is being done based on the filter rules defined to Policy Agent, then the default filter rules are updated by the VARY TCPIP,,OBEYFILE command, but filter rules defined in Policy Agent remain in effect. The ipsec -f default command must be issued to cause the default filter rules to be used.

For more information about [VARY TCPIP Command](#), see [z/OS Communications Server: IP System Administrator's Commands](#).

Examples

```
IPSEC
; Rule      SourceIp      DestIp      Logging    Prot        SrcPort      DestPort    Routing    Secclass
;
; Permit outbound IPv4 TCP traffic from local IP address 1.1.1.1 port 23 to remote IP address 2.2.2.2
; Permit inbound IPv4 TCP traffic from remote IP address 2.2.2.2 to local IP address 1.1.1.1 port 23
IPSECR 1.1.1.1      2.2.2.2    NOLOG      PROTO TCP    SRCPORT 23  DESTPORT *  ROUTING LOCAL

ITRACE statement

Use the ITRACE statement to control TCP/IP runtime tracing. This statement is used primarily for diagnostic purposes.

Syntax

Rule: Specify the parameters in the order shown here.

Parameters

ON

Specify ON to establish runtime tracing. If specified with no parameters, the trace defaults to CONFIG level 1, SUBAGENT level 1, COMMAND level 1, and AUTODAEMON tracing.

OFF

Specify OFF to terminate runtime tracing. If specified with no parameters, CONFIG, SUBAGENT, COMMAND, and AUTODAEMON tracing is turned off.

SUBAGENT

Turn internal trace for SNMP subagent ON or OFF.

CONFIG

Turn internal trace for configuration ON or OFF.

Restrictions:

- To trace the processing of specific TCP/IP profile statements, you must specify the ITRACE statement before the profile statements in the profile data set.
- You cannot specify the ITRACE statement inside a block statement. For example, do not place it within a VIPADYNAMIC/ENDVIPADYNAMIC block or a BEGINROUTES/ENDROUTES block.

COMMAND

Turn internal trace for command ON or OFF.

AUTODAEMON

Turn internal trace for the autolog subtask ON or OFF.

level

Indicates the tracing level to be established. Levels are as follows:

Levels for CONFIG

- 1**
ITRACE for all of config
- 2**
General level of tracing for all of config
- 3**
Tracing for configuration set commands
- 4**
Tracing for configuration get commands
- 5**
Tracing for syslog calls issued by config
- 100**
Tracing for the parser
- 200**
Tracing for scanner
- 300**
Tracing for mainloop
- 400**
Tracing for commands

Levels for SUBAGENT

- 1**
General subagent tracing
- 2**
General subagent tracing plus DPI traces
- 3**
General subagent tracing plus extended storage dump traces
- 4**
All trace levels

Levels for COMMAND

- 1**
ITRACE for all commands

Steps for modifying

To modify parameters for the ITRACE statement, use a VARY TCPIP,,OBEYFILE command with a data set that contains a new ITRACE statement.

Examples

```
ITRACE ON CONFIG 3
ITRACE OFF SUBAGENT
```

Results:

- Subagent trace output is directed to the syslog daemon. This daemon is configured by the */etc/syslog.conf* z/OS UNIX file and must be active.
- AUTOLOG trace output goes to the destination specified by the ALGPRINT setting in the TCP/IP cataloged procedure (TCPIPROC).

- CONFIG trace output goes to the destination specified by the CFGPRINT setting in the TCP/IP cataloged procedure (TCPIPROC). If CFGPRINT is not specified in TCPIPROC, the CONFIG component dynamically allocates a ddname of CFGPRINT.
- Command trace output goes to the hardcopy console log.

Usage notes

ITRACE ON commands are cumulative until an ITRACE OFF is issued.

NETACCESS statement

Use the NETACCESS statement to configure network access control. Specifically, it allows for the one-to-one mapping between a network, subnetwork or host and a Security Access Facility (SAF) resource name. The network specifications are used to build an internal data structure that maps networks, subnetworks and hosts to SAF resource names. The mapping is used to construct a complete resource name that is passed to the Security Product to determine the user's permission to access the network resource. The most specific mapping is used to determine the resource name for the SAF authorization check.

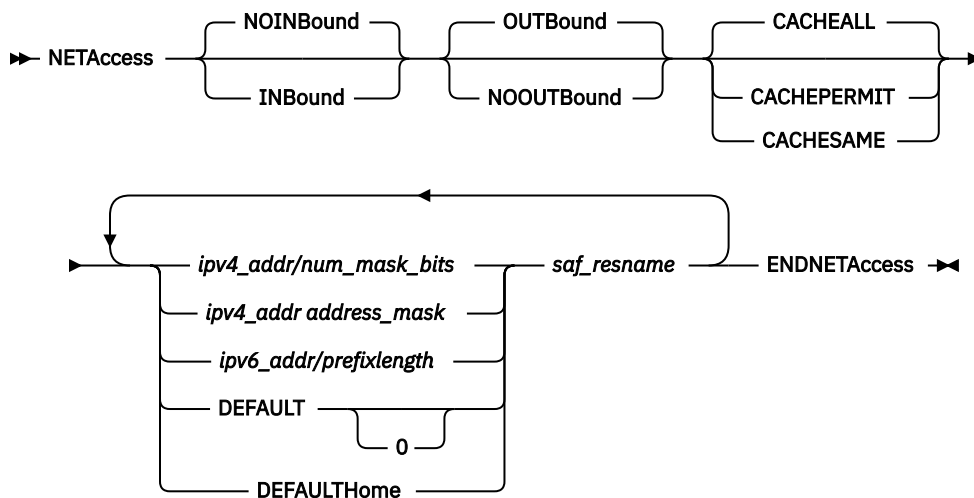

If the network resource does not have an assigned mapping, no SAF check is performed. If the network resource does have an assigned mapping, the SERVAUTH class must be active, the resource name must be defined, and the user ID making the request must have at least read access to the resource.

Inbound socket commands include application requests to bind a socket, accept a TCP connection and any command that transfers data into the application from a socket. Outbound socket commands include application requests to connect a socket and any command that transfers data from the application into the socket.

Multilevel-security is an enhanced security environment that can be configured on a z/OS Communications Server system. In this environment the Security Server and trusted resource managers enforce mandatory access control (MAC) policies in addition to the usual discretionary access control (DAC) policies. For more information about the multilevel-security environment and configuring z/OS Communications Server in that environment, see the multilevel-security information in the [z/OS Communications Server: IP Configuration Guide](#).

Syntax

Rule: Specify the parameters in the order shown here.

Parameters

NOINBOUND

Specifies that network access control checking is disabled for inbound socket commands. This is the default value.

INBOUND

Specifies that network access control checking is enabled for inbound socket commands.

OUTBOUND

Specifies that network access control checking is enabled for outbound socket commands. This is the default value.

NOOUTBOUND

Specifies that network access control checking is disabled for outbound socket commands.

CACHEALL

Specifies that when a SAF call is made to check a user's access to a security zone, the result is cached regardless of whether access is permitted or denied. Subsequent checks of the user's access to the security zone are resolved using the cached results. This is the default value.

This parameter allows an external security manager to write an audit record for only the first access check made for a user for each security zone.

CACHEPERMIT

Specifies that when a SAF call is made to check a user's access to a security zone, the result is cached when access is permitted, but not when access is denied. Subsequent checks of the user's access to a permitted security zone are resolved using the cached results. Subsequent checks of the user's access to a denied security zone are resolved by another SAF call.

This parameter allows an external security manager to write an audit record for only the first access check made for a user for each permitted security zone, and for all access checks made for a user for each denied security zone.

CACHESAME

Specifies that when a SAF call is made to check the access of a user to a security zone, the result is cached when access is permitted, but not when access is denied.

If the user is permitted to access the security zone, subsequent checks of the user access to the security zone are resolved using the cached results as long as the user associated with the socket and the IP address being accessed are unchanged. However, if the user that is associated with the socket changes or if the IP address being accessed changes from the previous packet that is received or sent over the socket, the next access check is resolved by another SAF call.

Subsequent checks of the user access to a denied security zone are resolved by another SAF call.

This parameter allows an external security manager to write an audit record for all denied access checks that are made for a user for each denied security zone and for the first of multiple successive access checks made for a socket under the same user and for the same IP address in a permitted security zone.

ipv4_addr/num_mask_bits

Specifies the network for which security product access control is required for user requests. The *num_mask_bits* field is used to create an address mask that is bit-contiguous from left to right. This address mask is logically ANDed with the *ipv4_addr* value to create the network address for which access control is required.

ipv4_addr address_mask

Specifies the network for which security product access control of user requests is required. The *address_mask* value is a bit mask (expressed in dotted decimal form) that is bit-contiguous from left to right. The *address_mask* value is logically ANDed with the *ipv4_addr* value to create the network address for which access control is required.

ipv6_addr/prefixlength

Specifies the IPv6 network for which security product access control is required. The *ipv6_addr* is an IPv6 address in colon-hexadecimal format. The *prefixlength* value is a decimal value specifying how many of the leftmost contiguous bits of the address comprise the prefix. The value is in the range of 1 - 128. IPv4-mapped IPv6 addresses and IPv6 addresses with the reserved prefix `::/96` are not allowed.

DEFAULT

Specifies that security product access control of user requests is required for any networks not specifically defined by other NETACCESS statement entries. If DEFAULTHOME is not specified, DEFAULT maps all addresses, local and remote, not mapped by other entries. If DEFAULTHOME is also specified, DEFAULT maps all remote addresses not mapped by other entries. Use of the *address_mask* value of 0 on this entry is deprecated.

DEFAULTHOME

Specifies that security product access control of user requests is required for all IP addresses that are local to this stack and not specifically defined by other NETACCESS statement entries. When this parameter is specified, security product access control of user requests is also required for addresses dynamically defined by SYSPLEX services and IPv6 link-local and global addresses that are automatically assigned for an interface.

saf_resname

Specifies the final qualifier of a security product resource name. The maximum length is eight characters. The profile name has the following format:

```
EZB.NETACCESS.sysname.tcpname.saf_resname
```

where

- EZB.NETACCESS is constant.
- *sysname* is the value of the MVS &SYSNAME. system symbol.
- *tcpname* is the name of the procedure used to start the TCP stack.
- *saf_resname* is the 1-8 character value following the network specification.

If the installation's SAF compliant security product (for example, RACF) supports the SERVAUTH class, the installation has activated the SERVAUTH class, a profile covering this resource name has been created in the SERVAUTH class, and the effective user ID is permitted to the resource, then it is allowed to access the network.

Restriction: You can not specify a 1-character value of 0 (zero) for *saf_resname*.

Steps for modifying

To modify any values on the NETACCESS statement, use a VARY TCPIP,,OBEYFILE command with a data set that contains a new NETACCESS statement. All existing network entries are deleted and replaced with the entries from the new NETACCESS statement. Active connections are reauthorized whenever the user ID the active connections are running under has changed or a new NETACCESS statement is loaded.

For more information about [VARY TCPIP Command](#), see [z/OS Communications Server: IP System Administrator's Commands](#).

Statement dependency

- A security server must be running and the SERVAUTH class must be active or all users are denied access to all network addresses mapped to a security zone.
- A resource profile name must be defined for a security zone or all users are denied access to all network addresses mapped to that security zone.
- Each user must be authorized to the security zone containing their static or Dynamic IP address.
- Servers such as HTTPD, FTPD, and INETD must have the user ID they accept work under authorized to all security zones that contain their intended clients' addresses.
- The FTP anonymous user (ANONYMO) must be authorized to the security zones containing clients that are allowed anonymous access.
- Users must be authorized to the security zone containing the name server address they use to avoid resolver failures.
- To protect security zone definitions, authority to modify the initial profile data set and issue VARY TCPIP,,OBEYFILE commands must be controlled.
- If you specify any IPv4 address and mask that applies to the INADDR_ANY address (0.0.0.0), servers that bind to INADDR_ANY will be affected. Ensure that these servers are authorized to the zone for the IPv4 address and mask or define an IPv4 address and mask entry of 0.0.0.0/32 in a unique security zone to control binds to the IPv4 INADDR_ANY address.
- When local addresses, or the DEFAULTHOME or DEFAULT parameters are specified and inbound checking is enabled, servers and other applications that explicitly bind must be permitted to the bind address.
 - Define address 127.0.0.1/8 or address ::1/128 into a security zone to control binds to the IPv4 or IPv6 loopback addresses, respectively.
 - Define address 0.0.0.0/32 or address ::/128 into a security zone to control binds to the IPv4 INADDR_ANY address, or to the IPv6 unspecified address (in6addr_any), respectively.
 - Use the BIND parameter on the PORT statement to optionally override binds to the IPv4 INADDR_ANY address, or to the IPv6 unspecified address (in6addr_any), with a bind to the specific local address specified on the BIND parameter. Permit the job to the security zone for that address.
- An IPv6 address should not be configured unless the TCP/IP stack is IPv6 enabled. If the stack is not IPv6 enabled, then all entries following an IPv6 entry are ignored and a message is issued.

Examples

```

NETACCESS      INBOUND      OUTBOUND      CACHEPERMIT ; check both ways, cache permits only
192.168.0.0/16          CORPNET ; Net address
192.168.113.19/32       HOST1 ; Specific host address
192.168.113.0           255.255.255.0 SUBNET1 ; Subnet address
192.168.112.0           255.255.248.0 SUBNET2 ; Subnet address
192.168.192.0/24        CAMPUS ; Subnet address
192.168.214.0/24        CAMPUS ; Subnet address
fe80::6:2900:1dc:21bc/128 HOST2 ; IPv6 specific host address
2001:0DB8::/16          GLBL ; IPv6 global network
DEFAULTHOME            HOME ; Optional Default local zone
DEFAULT                DEFZONE ; Optional Default zone
ENDNETACCESS

```

Usage notes

- The NETACCESS statement is optional.
- The initial profile or a VARY TCPIP,,OBEYFILE command data set can contain multiple NETACCESS statements.
- The first NETACCESS statement of each configuration data set that is executed resets the flags to OUTBOUND, NOINBOUND, and CACHEALL and clears any existing NETACCESS list prior to processing the flags and entries in that statement.
- Subsequent NETACCESS statements in the same configuration data set override any flags specified and add or replace specified entries in the list. Default flag values do not override previously specified values.
- Specifying a DEFAULT is optional. If you do not specify a default, Network Access Control applies only to the networks which are explicitly listed in NETACCESS statements.
- When an incorrect NETACCESS entry is encountered, all entries following that entry in that NETACCESS statement are ignored. IPv4 entries as well as any DEFAULT and DEFAULTHOME entries should precede the first IPv6 entry, to ensure that they are accepted, if the TCP/IP stack is not IPv6 enabled.
- If the new NETACCESS list is empty at the end of the configuration data set, Network Access Control is disabled.

NETMONITOR statement

Use the NETMONITOR PROFILE.TCPIP statement to activate or deactivate selected real-time TCP/IP network management interfaces (NMI). See [real time](#) in [z/OS Communications Server: IP Programmer's Guide and Reference](#) for more information about these services.

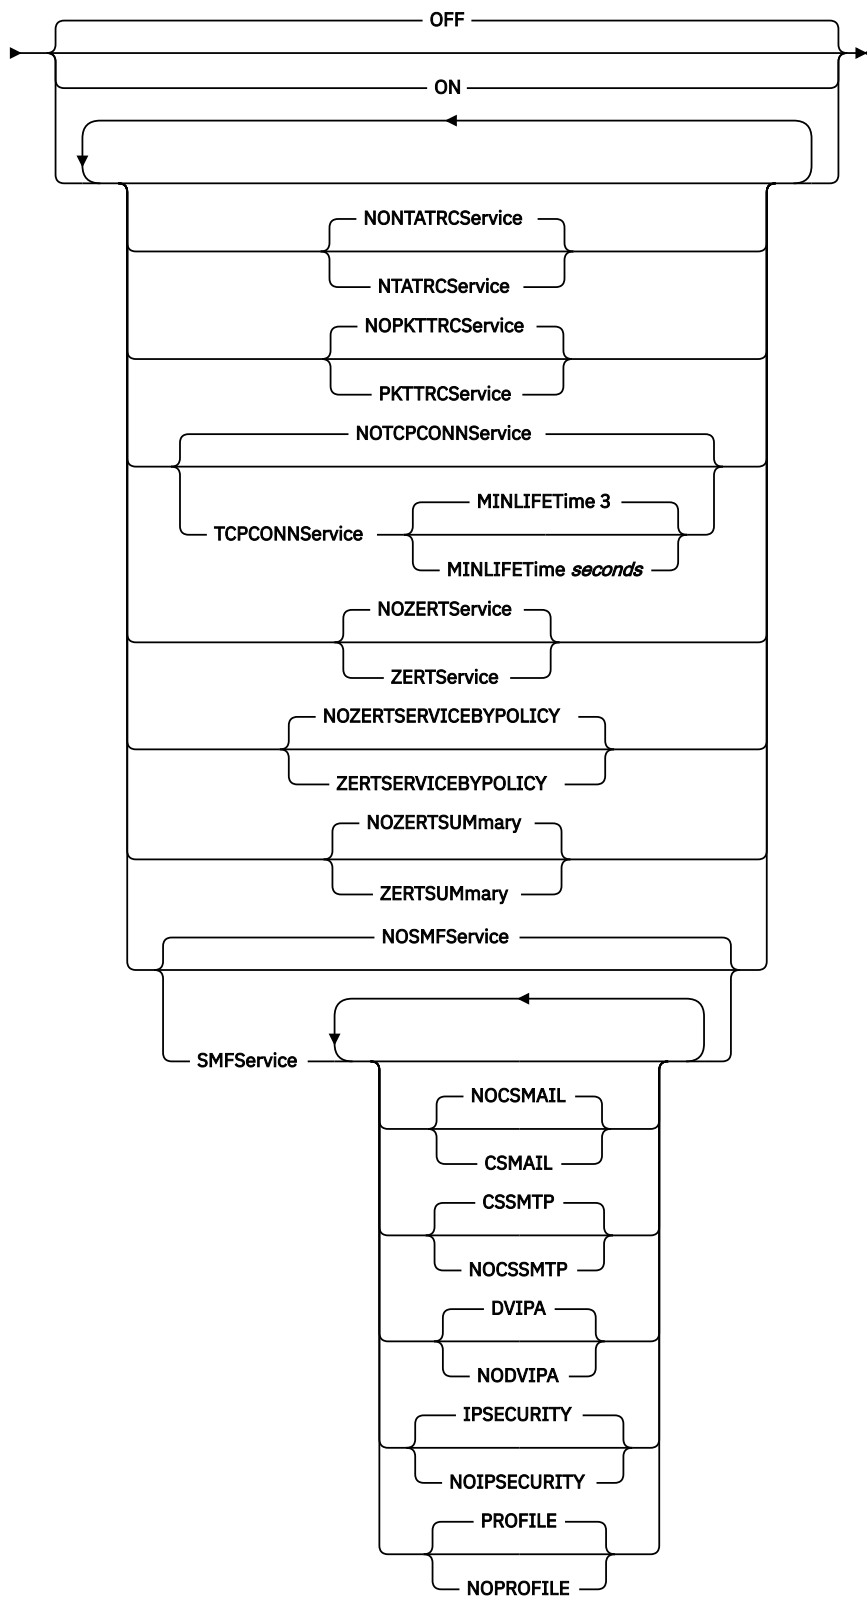

The NETMONITOR parameters, TCPCONNSERVICE, SMFSERVICE, ZERTSERVICE, ZERTSERVICEBYPOLICY, and ZERTSUMMARY, provide two functions:

- They control the availability of the real time SMF services that are associated with each parameter.
- They control the creation of the SMF 119 records that are supported by each service.

If you want your application to process only SMF 119 records by using these real time SMF services, you need to configure only the NETMONITOR profile statement. You do not need to request support for these SMF 119 records on the SMFCONFIG profile statement.

Syntax

Tip: Specify the parameters for this statement in any order.

Parameters

OFF

If specified in PROFILE.TCPIP at initialization, indicates that no supported network monitoring services should be started. This is the default value.

If specified using the VARY TCPIP,,OBEYFILE command and any network monitoring services are currently enabled, then those services are disabled, causing all current client connections to those services to be terminated.

ON

If specified in PROFILE.TCPIP at initialization, indicates that all supported network monitoring services should be started, and any options specific to those services (such as MINLIFETIME) set to their default values. If specified using the VARY TCPIP,,OBEYFILE command, then all network monitoring services that are not currently enabled are started, with any options specific to those services (such as MINLIFETIME) set to their default values. All services that are currently running at the time of a VARY TCPIP,,OBEYFILE command remain running, and any options specific to those services (such as MINLIFETIME) are unchanged. No other monitoring services are allowed on the NETMONITOR statement when the ON parameter is set.

NTATRCSERVICE | NONTATRCSERVICE

Specifies the behavior of the real time TCP/IP OSAENTA trace service (SYSTCPOT).

NONTATRCSERVICE

If this parameter is specified in PROFILE.TCPIP at initialization, it indicates that the OSAENTA trace service should not be activated on the stack. This is the default value. If specified using the VARY TCPIP,,OBEYFILE command and the OSAENTA service is currently enabled, the connections of the client applications are terminated and new connections are not accepted.

NTATRCSERVICE

Enables the OSAENTA trace service function to run on this TCP/IP stack. This service enables network management applications to access trace data that is collected for all OSAENTA traces. Access control should be provided for this service; see the [z/OS Communications Server: IP Configuration Guide](#) security topic for more information.

Tip: To ensure that a network management application that uses the real-time TCP/IP network management interface (NMI) receives OSAENTA data, verify the following requirements:

- The CTRACE SYSTCPOT component must be active. The component is activated by default. The TRACE CT,ON,COMP=SYSTCPOT,SUB=(tcpprocname) command activates the trace and the TRACE CT,OFF,COMP=SYSTCPOT,SUB=(tcpprocname) command deactivates the trace.
- The VARY TCPIP,,OSAENTA,ON command must be issued, or the OSAENTA statement in the TCP/IP profile is used to specify the parameters to collect data from an OSA-Express adapter. For trace data collection from an OSA-Express adapter, verify the following requirements:
 - An extra DATAPATH device must be defined for the TRLE for the OSA-Express adapter.
 - The hardware definitions for the OSA-Express adapter must be defined to allow OSAENTA trace data to be collected.

For more information, see [real time](#) in [z/OS Communications Server: IP Programmer's Guide and Reference](#).

PKTTRCSERVICE | NOPKTTRCSERVICE

Specifies the behavior of the real time TCP/IP packet trace service (SYSTCPDA).

NOPKTTRCSERVICE

If specified in PROFILE.TCPIP at initialization, this parameter indicates that the packet trace service should not be allowed on the stack. This is the default value. If specified using the VARY TCPIP,,OBEYFILE command and packet trace service is currently enabled, the client applications connections are terminated and new connections are not accepted.

PKTTRCSERVICE

Enables the packet trace service function to run on this TCP/IP stack. This service enables network management applications to access trace data collected for any active packet traces

or data traces. Access control should be provided for this service; see the [z/OS Communications Server: IP Configuration Guide](#) security topic for more information.

Tip: To ensure that a network management application that uses the real-time TCP/IP NMI receives packet trace (PKTTRACE) or data trace (DATTRACE) data, verify the following requirements:

- The CTRACE SYSTCPDA component must be active. The component is activated by default when TCP/IP starts. The TRACE CT,ON,COMP=SYSTCPDA,SUB=(tcpprocname) command activates the trace and the TRACE CT,OFF,COMP=SYSTCPDA,SUB=(tcpprocname) command deactivates the trace.
- If the network management application collects packet trace data, the VARY TCPIP,,PKTTRACE,ON command must be issued to specify the parameters to collect trace data from TCP/IP interfaces.
- If the network management application collects data trace data, the VARY TCPIP,,DATTRACE,ON command must be issued to specify the parameters to collect application data.

For more information, see [real time](#) in [z/OS Communications Server: IP Programmer's Guide and Reference](#).

TCPCONNSERVICE | NOTCPCONNSERVICE

Controls the behavior of the real time TCP connection SMF NMI service (SYSTCPCN), and the generation of SMF 119 records that are supported on this service.

NOTCPCONNSERVICE

If the parameter is specified in PROFILE.TCPIP at initialization, this parameter indicates that the TCP connection SMF NMI service should not be started on the stack. This is the default value. If the parameter is specified by the VARY TCPIP,,OBEYFILE command, this parameter indicates that the service should be stopped.

TCPCONNSERVICE

Enables the real time TCP connection SMF NMI service to run on this TCP/IP stack. The service runs as a subtask in the TCP/IP stack address space. This service provides an interface for network management applications to obtain information about TCP connections on this stack. For more information about this service and a list of the SMF 119 records supported on this service, see [real time](#) in [z/OS Communications Server: IP Programmer's Guide and Reference](#).

Enabling or disabling this service has no effect on SMF 119 records written to the MVS SMF data sets due to the SMFCONFIG profile statement. You should provide access control for this service. For more information, see [z/OS Communications Server: IP Configuration Guide](#).

MINLIFETIME *seconds*

The minimum connection lifetime, specified in seconds, for connections reported by the TCP connection information server. The server waits for this period before recording information about new connections; if the connection has closed in the meantime, then the connection is not reported by the TCP connection information server. This parameter can have a value from 0 to 60 seconds; the default, if not specified, is 3 seconds.

If 0 is coded for this option, then all connections are reported.

This option is used to suppress short-lived connections from being reported over the TCP connection information service. In order to ensure that all connections are reported, a 0 should be coded for this option.

SMFSERVICE | NOSMFSERVICE

Controls the behavior of the real time SMF NMI service (SYSTCPSM), and the generation of SMF 119 records that are supported on this service.

NOSMFSERVICE

If the parameter is specified in PROFILE.TCPIP at initialization, this parameter indicates that the real time SMF NMI service should not be started on the stack. This is the default value. If the parameter is specified using the VARY TCPIP,,OBEYFILE command, this parameter indicates that the service should be terminated.

SMFSERVICE

Enables the real time SMF NMI service to run on this TCP/IP stack. The service runs as a subtask in the TCP/IP stack address space. This service provides an interface for network management applications to obtain stack information in the form of SMF 119 records. This parameter can also be used, with or without subparameters, to request the creation of specific SMF 119 records which are then provided to applications that are connected to this service. For more information about this service and a list of all the SMF 119 records supported on this service, see [real time in z/OS Communications Server: IP Programmer's Guide and Reference](#).

Certain FTP and Telnet SMF records are created by default. You must specify NOSMFSERVICE to stop the creation of these records. The creation of other SMF records is controlled by specifying the subparameter associated with the specific SMF record.

Rules:

- If you have specified the SMFSERVICE parameter (with or without subparameters), certain FTP and Telnet SMF records are created. There are no subparameters to control the creation of these SMF records.
- You can specify only the SMFSERVICE parameter, without any subparameters, to enable the creation of all SMF 119 records that this parameter controls, except for the CSSMTP SMF MAIL records (SMF 119 subtype 50). To enable the CSSMTP SMF MAIL records, you must explicitly specify the CSMAIL subparameter.
- For the SMF records whose creation is controlled by subparameters, specify the SMFSERVICE parameter with one or more subparameters to enable or disable the creation of the SMF records for the specified subparameter only.

Enabling or disabling this service has no effect on SMF 119 records written to the MVS SMF data sets due to the SMFCONFIG profile statement, or the FTP.DATA or CSSMTP SMF119 configuration statements. For more information, see [z/OS Communications Server: IP Configuration Guide](#).

CSMAIL | NOCSMAIL

Controls the creation of the real time CSSMTP SMF MAIL records. (SMF 119 Subtype 50 (MAIL))

CSMAIL

Specifies that the real time CSSMTP SMF MAIL records should be created and provided on the real time SMF NMI service.

Special considerations for CSSMTP application and NETMONITOR in a CINET environment:

- The CSSMTP application can be started with the **-p** parameter to set stack name. All the SMF records are written to the real time SMF NMI associated with the stack whose name was specified on the **-p** parameter. This forces connection-oriented SMF records (CONNECT) and non-connection oriented SMF records (CONFIG, SPOOL, MAIL and STATS) to go to the same stack. The CSSMTP and CSMAIL NETMONITOR parameters should be specified in the profile data sets of the stack name whose name is specified on the **-p** parameter.
- If the CSSMTP application is started without the **-p** parameter and multiple stacks are active, then a network management application cannot determine the stack that records will be written to. So, the CSSMTP and CSMAIL NETMONITOR parameters should be specified in the profile data sets of all stacks, so that network management applications can obtain all the records. The network management application will not get redundant records.

NOCSMAIL

Specifies that the real time CSSMTP SMF MAIL records should not be created. This is the default.

CSSMTP | NOCSSMTP

Controls the creation of the real time CSSMTP SMF records. (SMF 119, Subtype 48 (CONFIG), 49 (CONNECT), 51 (SPOOL), and 52 (STATS)).

CSSMTP

Specifies that the real time CSSMTP SMF records should be created and provided on the real time SMF NMI service. This is the default.

Special considerations for CSSMTP application and NETMONITOR in a CINET environment:

- The CSSMTP application can be started with the **-p** parameter to set stack affinity. All the SMF records are written to the real time SMF NMI associated with the stack whose name was specified on the **-p** parameter. This forces connection-oriented SMF records (CONNECT) and non-connection oriented SMF records (CONFIG, SPOOL, MAIL and STATS) to go to the same stack. The CSSMTP and CSMail NETMONITOR parameters should be specified in the profile data sets of the stack name whose name is specified on the **-p** parameter.
- If the CSSMTP application is started without the **-p** parameter and multiple stacks are active, then a network management application cannot determine the stack that records will be written to. So, the CSSMTP and CSMail NETMONITOR parameters should be specified in the profile data sets of all stacks, so that network management applications can obtain all the records. The network management application will not get redundant records.

NOCSSMTP

Specifies that the real time CSSMTP SMF records should not be created.

DVIPA | NODVIPA

Controls the creation of the real time sysplex (dynamic virtual IP address) SMF records.

DVIPA

Specifies that the real time sysplex SMF records should be created and provided on the real time SMF NMI service.

NODVIPA

Specifies that the real time sysplex SMF records should not be created.

IPSECURITY | NOIPSECURITY

Controls the creation of the real-time IPsec SMF records.

IPSECURITY

Specifies that the real time IPsec SMF records should be created and provided on the real time SMF NMI service.

NOIPSECURITY

Specifies that the real time IPsec SMF records should not be created.

PROFILE | NOPROFILE

Controls the creation of the real-time TCP/IP stack profile SMF records and TN3270 Telnet server (Telnet) profile SMF records.

PROFILE

Specifies that the real-time TCP/IP stack profile SMF records (subtype 4) and TN3270 Telnet profile SMF records (subtype 24) should be created and provided on the real-time SMF NMI service.

NOPROFILE

Specifies that the real-time TCP/IP stack profile SMF records and TN3270 Telnet profile SMF records should not be created.

ZERTService|NOZERTService

Controls the behavior of the real time z/OS Encryption Readiness Technology (zERT) Detail SMF NMI service (SYSTCPEP), and the generation of SMF 119 zERT connection detail records for TCP and Enterprise Extender connections at connection initiation, connection termination, and when security characteristics for the connection change.

NOZERTService

If specified in PROFILE.TCPIP at initialization, this parameter indicates that SMF 119 zERT connection detail records should not be generated for TCP and Enterprise Extender connections at

connection initiation, connection termination, and when security characteristics for the connection change. The zERT Detail SMF NMI service (SYSTCPEP) will not be started on the stack if both NOZERTSERVICE and NOZERTSERVICEBYPOLICY are in effect. NOZERTSERVICE is the default value.

If the parameter is specified by the VARY TCP,IP,,OBEYFILE command, this parameter indicates that SMF 119 zERT connection detail records should no longer be generated for TCP and Enterprise Extender connections at connection initiation, connection termination, and when security characteristics for the connection change. The SYSTCPEP service will be stopped if both NOZERTSERVICE and NOZERTSERVICEBYPOLICY are in effect.

ZERTService

Enables the real time zERT Detail SMF NMI service to run on this TCP/IP stack. The service runs as a subtask in the TCP/IP stack address space. This service provides an interface for network management applications to obtain information, in the form of zERT connection detail records, about the cryptographic protection of the TCP and Enterprise Extender traffic on this stack. zERT connection detail records are created when zERT discovery is enabled and TCP and Enterprise Extender connections are initiated or terminated, or when the security characteristics of those connections change. These records are also created when zERT discovery is enabled or disabled dynamically. For more information about this service, see [real time in z/OS Communications Server: IP Programmer's Guide and Reference](#).

Rules:

- zERT connection detail SMF 119 records are only created when the z/OS Encryption Readiness Technology function has been activated by specifying the ZERT parameter on the GLOBALCONFIG profile statement.
- Both ZERTSERVICE and ZERTSERVICEBYPOLICY write zERT connection detail records SMF 119 records through the SYSTCPEP service.
- Creation of the zERT connection detail SMF 119 records of subtype 11 by zERT policy-based enforcement is not controlled by the ZERTSERVICE parameter. It is controlled by the ZERTSERVICEBYPOLICY parameter.

Tip: Enabling or disabling this service has no effect on SMF 119 records written to the MVS™ System Management Facility due to the SMFCONFIG profile statement.

ZERTSERVICEBYPOLICY|NOZERTSERVICEBYPOLICY

Controls the behavior of the real time zERT Detail SMF NMI service (SYSTCPEP), and the generation of SMF 119 zERT connection detail records for TCP connections when the connections map to zERT policy-based enforcement (ZERT) rules with an audit action.

NOZERTSERVICEBYPOLICY

If specified in PROFILE.TCPIP at initialization, this parameter indicates that SMF 119 zERT connection detail records should not be generated for TCP connections when the connections map to ZERT rules with an audit action. The zERT Detail SMF NMI service (SYSTCPEP) will not be started on the stack if both NOZERTSERVICE and NOZERTSERVICEBYPOLICY are in effect. NOZERTSERVICEBYPOLICY is the default value.

If the parameter is specified by the VARY TCP,IP,,OBEYFILE command, this parameter indicates that SMF 119 zERT connection detail records should no longer be generated for TCP connections when the connections map to ZERT rules with an audit action. The SYSTCPEP service will be stopped if both NOZERTSERVICE and NOZERTSERVICEBYPOLICY are in effect.

ZERTSERVICEBYPOLICY

Enables the real time zERT Detail SMF NMI service to run on this TCP/IP stack. The service runs as a subtask in the TCP/IP stack address space. This service provides an interface for network management applications to obtain information, in the form of zERT connection detail records created by the zERT policy-based enforcement, when TCP connections map to a ZERT policy rule with audit action. For more information on the audit action, see “ZERTAction statement” on page [1107](#). zERT connection detail records are also created when zERT discovery is enabled or disabled

dynamically. For more information about this service, see [real time in z/OS Communications Server: IP Programmer's Guide and Reference](#).

Rules:

- zERT connection detail SMF 119 records are only created when the z/OS Encryption Readiness Technology function has been activated by specifying the ZERT parameter on the GLOBALCONFIG profile statement.
- Both ZERTSERVICE and ZERTSERVICEBYPOLICY write zERT connection detail records through the SYSTCPEP service.
- Creation of zERT connection detail SMF 119 records of subtype 11 when TCP and Enterprise Extender connections are initiated or terminated, or when the security characteristics of those connections change, is not controlled by the ZERTSERVICEBYPOLICY parameter. It is controlled by the ZERTSERVICE parameter.

Tip: Enabling or disabling this service has no effect on SMF 119 records written to the MVS™ System Management Facility due to the SMFCONFIG profile statement.

ZERTSUMmary|NOZERTSUMmary

Controls the behavior of the real time z/OS Encryption Readiness Technology (zERT) Summary SMF NMI service (SYSTCPES), and the generation of SMF 119 zERT summary records that are supported on this service.

NOZERTSUMmary

If specified in PROFILE.TCPIP at initialization, this parameter indicates that the zERT Summary SMF NMI service should not be started on the stack. This is the default value. If the parameter is specified by the VARY TCPIP,,OBEYFILE command, this parameter indicates that the service should be stopped.

ZERTSUMmary

Enables the real time zERT Summary SMF NMI service to run on this TCP/IP stack. The service runs as a subtask in the TCP/IP stack address space. This service provides an interface for network management applications to obtain summary information, in the form of SMF type 119 zERT summary records, about the cryptographic protection of the TCP and Enterprise Extender traffic on this stack. For more information about this service, see [real time in z/OS Communications Server: IP Programmer's Guide and Reference](#).

Rule: zERT summary SMF 119 records are only created when the zERT aggregation function has been activated by specifying the ZERT AGGREGATION parameter on the GLOBALCONFIG profile statement.

Tip: Enabling or disabling this service has no effect on SMF 119 records written to the MVS™ System Management Facility due to the SMFCONFIG profile statement.

Steps for modifying

If NETMONITOR appears in a VARY TCPIP,,OBEYFILE command data set without any options, then no change occurs. NETMONITOR OFF must be explicitly coded in a VARY TCPIP,,OBEYFILE command data set in order to turn off all active services.

If a NETMONITOR statement in a VARY TCPIP,,OBEYFILE command data set contains service-specific keywords, then those services which are not specified on the statement remain unaffected by the command processing.

If any service is disabled by a VARY TCPIP,,OBEYFILE command, then clients connected to that service have their connections terminated.

If the MINLIFETIME setting is changed by a VARY TCPIP,,OBEYFILE command, then existing TCP connections are not affected by the new minimum lifetime value. Only new TCP connections are affected by the updated minimum lifetime value.

Related topic

- [“SMFCONFIG statement” on page 224](#)

OSAENTA statement

Use the OSAENTA statement to control the OSA Network Traffic Analyzer (OEAENTA) tracing facility in the OSA adapter. You can use this statement to select frames as candidates for tracing and subsequent analysis; OSAENTA traces are recorded externally using the TRACE command. See [z/OS Communications Server: IP Diagnosis Guide](#) for information about the steps required to perform an OSAENTA trace.

The OSAENTA statement consists of two parts. One part defines the OSA that is to be traced and characteristics of the tracing. A second part turns tracing on or off or clears the trace settings. The tracing characteristics are identified by filters which specify under which conditions a frame should be traced. A frame must meet all the conditions specified on the OSAENTA statements for it to be traced. For example, if the OSAENTA statement identifies PROTOCOL=TCP and PORTNUM=21, only IP packets that have both a protocol of TCP and a port of 21 are traced. Only one value can be specified for a given filter on one OSAENTA statement.

Multiple OSAENTA statements can be included in the PROFILE.TCPIP data set, and can control tracing for multiple OSAs. The filters on multiple OSAENTA statements are cumulative for a given OSA port. Each OSAENTA statement that specifies filters adds to the filters that are already in effect for that OSA port. You can use multiple OSAENTA statements, multiple filter values can be assigned to each filter. There is a limit of eight filter values for each filter for each OSA port. For example, you can specify up to eight IP protocols, up to eight VLAN IDs, and so on. For IP addresses, you can specify up to eight IPv4 addresses and up to eight IPv6 addresses. If a frame matches any of the values for that filter, it is considered to meet the condition of that particular filter. For example, if IPADDR=9.67.1.1,PROTO=TCP, and PORTNUM=21 is specified on one OSAENTA statement for OSA1, and IPADDR=9.67.1.2 is specified on another OSAENTA statement for OSA1, all frames sent to either IP address 9.67.1.1 or 9.67.1.2 with a protocol of TCP and a port of 21 are traced.

The OSAENTA statement dynamically defines a QDIO interface to the OSA being traced, called an OSAENTA interface. That interface is used exclusively for capturing OSA Network Traffic Analyzer traces.

The OSAENTA statement enables an installation to trace data from other hosts connected to OSA. The trace data collected should be considered confidential and TCP/IP system dumps and external trace files containing this trace data should be protected.

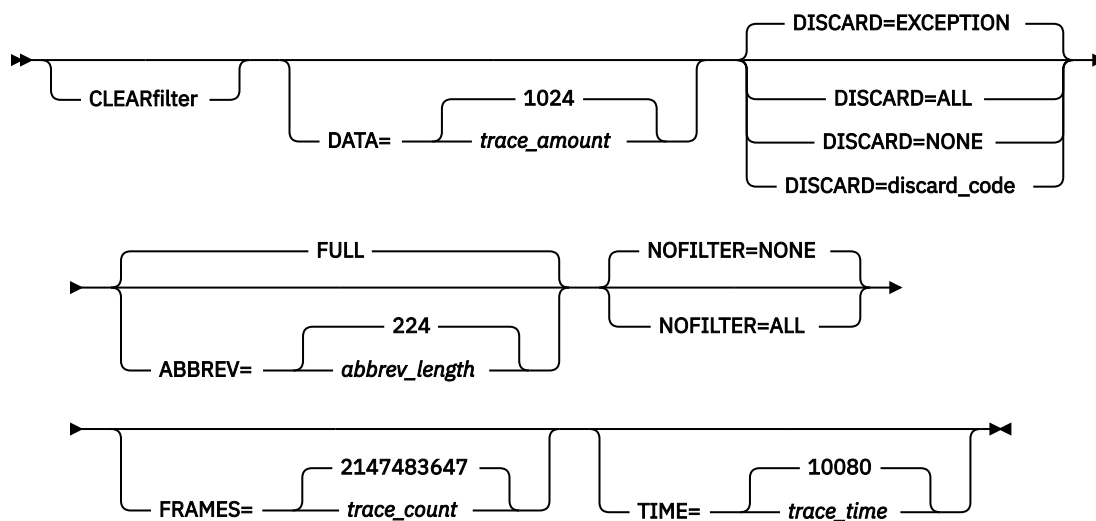

If an error is found while parsing the OSAENTA statement, an error message is generated and the statement is ignored.

Syntax

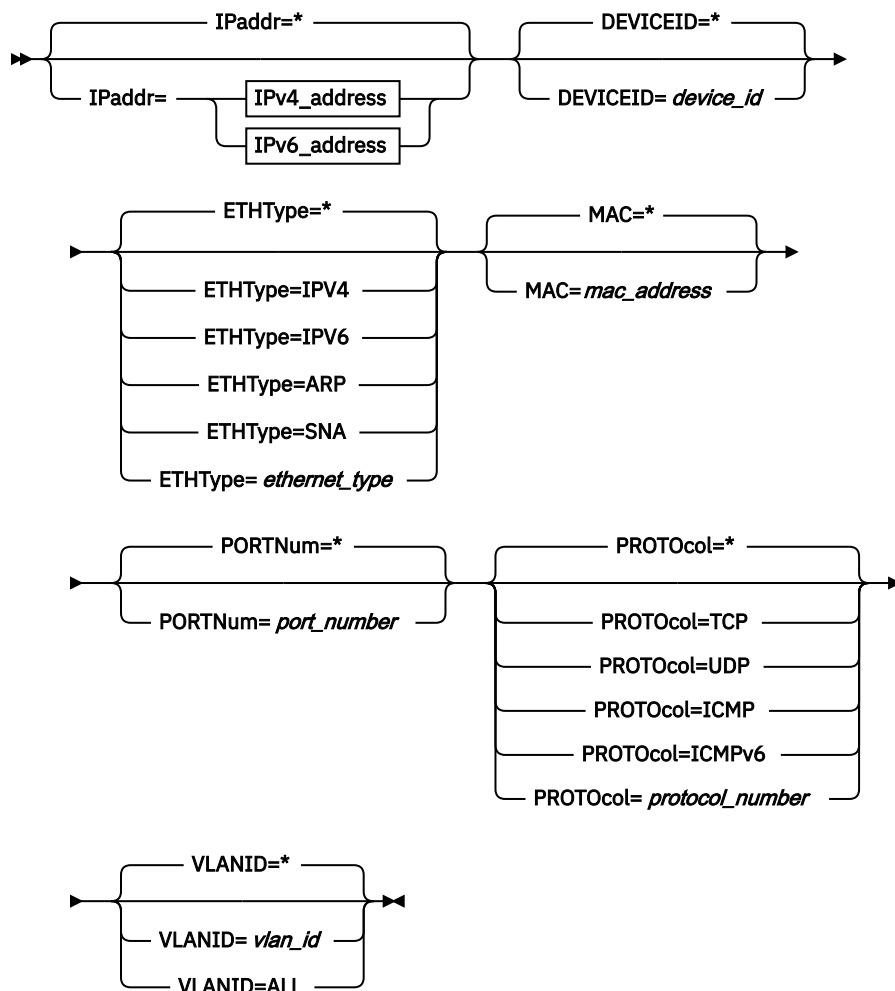

Tip: Specify all parameters, except the PORTNAME parameter, for this statement in any order. If a keyword on a given statement is specified multiple times, the last value specified is used.

Parameter

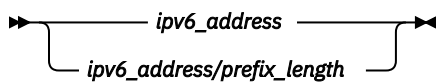

Filter

IPv4_address

IPv6_address

Parameters

PORTNAME=osa_port_name

Specifies the required port name of the OSA for which you want to enable tracing. This is the same port name that is defined on the PORTNAME keyword of the VTAM TRLE statement. This is the same port name that is either defined on the PORTNAME keyword of the VTAM TRLE statement or is dynamically created by VTAM for OSX interfaces (configured with the CHPID parameter) or for OSM interfaces. For more information about [TCP/IP in an ensemble](#), see [z/OS Communications Server: IP Configuration Guide](#).

Tip: You do not also have to define the OSA-Express to TCP/IP using the DEVICE or LINK statements or INTERFACE statement or activate it on the tracing stack in order to collect trace data from other stacks using that OSA-Express. For an OSX interface configured with the CHPID parameter or for an OSM interface, specify the port name according to the VTAM naming convention for these dynamic TRLEs, and VTAM will dynamically create the TRLE when you activate the OSAENTA interface. For details about the naming convention for these dynamically generated TRLEs, see [z/OS Communications Server: SNA Network Implementation Guide](#).

Restriction: OSA does not allow multiple stacks to concurrently use the tracing function for a given OSA feature.

ABBREV

Specifies the amount of data that is to be traced for each frame. You can specify a length in the range 64 - 65472 or use the default value 224. The value is rounded up to the next 32 byte boundary. The ABBREV parameter can be used to control the volume of data stored in the trace buffers and file. The actual amount of data traced might be limited by the OSA adapter.

Tip: The size value that OSA returns is the maximum amount of trace data that OSA can return. Depending on the model, OSA can return fewer bytes than the maximum. OSA-Express3 or later version returns only 120 bytes for unicast packets, and return up to the maximum amount of trace data for multicast, broadcast, or unroutable packets.

Guideline: Use a large value or specify the FULL parameter if you want to maximize the amount of data traced for each packet; TCP segmentation offload packets are traced before the packet is segmented, and can be larger than the largest frame size on the LAN. See the [segmentation offload information](#) in [z/OS Communications Server: IP Configuration Guide](#) for information about which parameters affect the size of TCP segmentation offload packets.

CLEARFILTER

Clears any previous OSAENTA trace filters for the specified OSA port name.

If you specify the CLEARFILTER parameter and the OSAENTA interface is active, either all frames are traced or no frames are traced, depending on the setting of the NOFILTER parameter. The trace buffers are likely to fill up very quickly if you clear all the filters without setting new filters to filter out an adequate percentage of the packets.

Tip: Specifying CLEARFILTER clears all filters. To clear all values for a single filter, use OSAENTA and specify an asterisk (*) for the filter value.

DATA

Specifies the number of megabytes of data to be collected before stopping the trace. The minimum value is 1 megabyte, the default value is 1024 megabytes, and the maximum value is 2147483647 megabytes. If a value of 0 is specified, then the maximum value is set.

Result: If the OSAENTA interface is inactive, then the data limit takes effect when the OSAENTA trace is enabled with the ON parameter. If the OSAENTA interface is active and the *trace_amount* value is modified, then the stack resets the data counter to 0 and puts the new data limit into effect.

DEL

Removes the OSAENTA interface definition. The OSAENTA interface must be inactive in order to specify the DELETE parameter. To deactivate the OSAENTA interface, you can respecify the OSAENTA statement with the OFF parameter, or use the V TCPIP,OSAENTA command with the OFF parameter.

DEVICEID

Specifies the 8-digit hexadecimal value that identifies a host that is sharing the OSA feature. The value is in the form *csmfclua*, where:

cs

The channel subsystem ID for this datapath device.

mf

The LPAR Multiple Image Facility ID for the LPAR using this datapath device.

cl

The control unit logical identifier for this datapath device.

ua

The unit address for this datapath device.

Each identifier is a 2-digit hexadecimal value in the range 00 - FF.

If the frame was either inbound or outbound to the host identified by the *device_id* value, then the frame meets the criteria for this filter. If the DEVICEID option has been omitted or an asterisk (*) is specified, then all packets meet the criteria for this filter.

Tip: You can obtain the *device_id* values for any user of the OSA feature by using the Hardware Management Console (HMC). For a data device that is active on a z/OS stack, you can obtain the *device_id* value for that data device from message IST2190I in the output from the D NET,TRL,TRLE=name command.

DISCARD

Specifies which frames that are discarded by the OSA feature should be traced. Discarded frames include frames that OSA feature could not transmit outbound or could not forward inbound. Discarded frames that match the DISCARD= setting are traced whether or not they match any filters that might be in effect. You can specify the DISCARD parameter on multiple OSAENTA statements. The ALL and NONE values reset any previous DISCARD values that are in effect, and the EXCEPTION value or a discard code resets the setting ALL or NONE. The EXCEPTION value and discard_code values are cumulative for a given OSA feature.

ALL

Specifies that all frames that are discarded by the OSA feature are traced. This includes both exception conditions and expected discards, such as ARP packets received for non-registered IP addresses or packets for non-supported ethernet types.

EXCEPTION

Specifies that frames discarded by the OSA feature for exception conditions are traced. These are frames that are typically discarded for anomalous conditions. Examples of anomalous conditions are:

- An inbound IP packet destined for an IP address that is not registered with the OSA feature and no PRIROUTER or SECROUTER parameter is in effect.
- An outbound IP packet that could not be delivered because no storage was available within the OSA feature.

Rule: If the EXCEPTION value and discard codes are specified on multiple OSAENTA statements, all frames that are discarded for exception conditions and all frames that are discarded for any of the discard codes in effect are traced.

Restriction: When the EXCEPTION value is specified, only seven or fewer discard codes can be active for one OSA feature.

NONE

Specifies that no discarded frames are traced.

discard_code

Specifies that frames discarded for the reason specified by the *discard_code* value are traced. This option should be used only under the direction of IBM service personnel. Valid values are in the range 1 - 4087. As many as 8 discard codes can be active for one OSA feature.

Rule: The CLEARFILTER parameter does not affect the state of the DISCARD parameter.

Result: A frame can be traced twice; once when the packet is passed to the OSA feature, and again as a discarded packet during the processing of the packet.

Guideline: To reset the current set of active discard codes, specify DISCARD=ALL or NONE followed by OSAENTA statements with the DISCARD parameters that you want to specify.

ETHTYPE

Specifies the Ethernet frame type to be traced. This can be specified as one of the literals IPV4, IPV6, ARP, SNA or as a hexadecimal number in the range 0600 - FFFF (IPV4=0800, IPV6=86DD, ARP=0806, and SNA=80D5). If the ETHTYPE parameter has been omitted or an asterisk (*) is specified, then all packets meet the criteria for this filter.

FRAMES

Specifies the number of frames to be recorded before tracing is stopped. The minimum value is 100 frames. The maximum value is 2147483647 frames. If a value of 0 is specified, then the maximum value is set.

Result: If the OSAENTA interface is inactive, then the FRAMES limit takes effect when the OSAENTA trace is enabled with the ON parameter. If the OSAENTA interface is active and the *trace_count* value is modified, then the stack resets the frame counter to 0 and puts the new frame limit into effect.

FULL

Specifies that the entire frame is to be traced if possible. (OSA might limit the amount of data actually traced.)

IPADDR

Specifies an IP address (either a 32-bit IPv4 address in dotted decimal notation, or a 128-bit IPv6 address in colon hexadecimal notation) to be compared with both the source and destination addresses of inbound and outbound packets. If either the source or destination address of a packet matches the specified IP address, the frame meets the criteria for this filter. If the IPADDR option is omitted or an asterisk (*) is specified, then all packets meet the criteria for this filter. If the IPADDR filter is specified, then only frames containing IP packets or ARP packets are subject to tracing.

If an IPv4 address is specified, then the */num_mask_bits* variable (range 1-32) can be used to designate a subnet. The default number of bits is 32.

If an IPv6 address is specified, then an optional *prefix_length* value (range 1-128) can be specified. The default *prefix_length* value is 128.

Note:

1. If an IP address has never been specified on the OSAENTA command for the OSA portname, IPADDR=* is the default.
2. If IPADDR is specified on the command, you can specify one of the following values:
 - *
 - An IPv4 address
 - An IPv6 address

There is no default if the IPADDR parameter is specified alone. If this parameter is specified by itself, it is a syntax error. Specify IPADDR=* to remove all previous IP addresses from the filter. Specify IPADDR=*IPv4_address* or IPADDR=*IPv6_address* to add this address to the list of addresses for the IP address filter.

MAC

Specifies the twelve hexadecimal digits of the MAC address. The address is compared with both the source and destination MAC address of inbound and outbound frames. If either the source or

destination address of a frame matches the specified MAC address, the frame meets the criteria for this filter. If the MAC option has been omitted or an asterisk (*) is specified, then all packets meet the criteria for this filter.

NOFILTER=ALL|NONE

Specifies the filtering behavior when all filters (DEVICEID, MAC, ETHTYPE, VLANID, IPADDR, PROTOCOL and PORTNUM) have been cleared or are inactive. This condition might exist if no filters have been specified, if the CLEARFILTER parameter is specified, or when the current setting for every filter is set to an asterisk (*). When NOFILTER=ALL, all packets are traced. When NOFILTER=NONE is specified, no packets are traced. The NOFILTER parameter applies only to packets that were not discarded by the OSA feature. The DISCARD parameter controls tracing of discarded packets.

Guideline: If you clear filters using the CLEARFILTER parameter with the OSAENTA interface active, and specify NOFILTER=ALL, ensure that you also specify sufficient new filters. The trace buffers are likely to fill up very quickly if you clear all the filters without setting new filters to filter out an adequate percentage of the packets.

OFF

Disables OSA feature tracing for the specified OSA feature port name by stopping the OSAENTA interface. The trace parameters and filters remain in effect if you subsequently re-enable the OSAENTA trace.

ON

Enables OSA feature tracing for the specified OSA port name by starting the OSAENTA interface using the OSAENTA trace parameters and filters that are currently in effect. If the OSAENTA interface is already active, then the ON keyword causes the stack to reset the active counters on the DATA, FRAMES, and TIME limits.

Guideline: Ensure that you have specified sufficient trace filters before starting the trace. The trace buffers are likely to fill up very quickly if you activate the trace with either no filters (NOFILTER=ALL) or with a set of filters that does not filter out an adequate percentage of the packets.

PORTNUM

Specifies a port number in the range 1 - 65535. The port number is compared with the destination or source port of inbound and outbound packets. If the port of a packet is the same as the specified port number, then the frame meets the criteria for this filter. This comparison is performed only for packets using the TCP or UDP protocol; frames using other protocols are not traced when a PORTNum filter is in effect. If the PORTNum parameter is omitted or an asterisk (*) has been specified, then all packets meet the criteria for this filter. If the PORTNum filter is used, then only frames containing IP packets are subject to tracing.

IPSec Encapsulating Security Payload (ESP) packets cannot be traced by port number because the TCP or UDP headers are encrypted.

PROTOCOL

Specifies the IP protocol type to be traced. This can be specified as one of the literals TCP, UDP, ICMP, or ICMPV6, or as a number in the range 0 - 255 (ICMP=1, TCP=6, UDP=17, ICMPV6=58). If the PROTOCOL parameter is omitted or an asterisk (*) has been specified, then all packets meet the criteria for this filter. If a PROTOCOL protocol value is specified and the frame does not contain an IP protocol packet, then the frame is not traced. If the PROTOCOL filter is used, then only frames containing IP packets are subject to tracing.

Rule: For encapsulated packets, OSAENTA bases collection on whether the specified protocol filter matches the outermost packet protocol. For example, if TCP was specified as the protocol filter, and a TCP packet was received encapsulated in an IPSEC packet with protocol 50, this TCP packet is not collected. Protocol 50 must be specified to collect these packets.

TIME

Specifies the number of minutes that trace records are recorded before stopping. The minimum value is 1 minute. The maximum value is 10080 minutes (7 days). If a value of 0 is specified, then the maximum value is set.

Result: If the OSAENTA interface is inactive, then the time limit takes effect when the OSAENTA trace is enabled with the ON parameter. If the OSAENTA interface is active and the *trace_time* value is modified, then the stack resets the time counter to 0 and puts the new time limit into effect.

VLANID

Specifies a VLAN identifier value, which is a decimal number in the range 0 - 4094. The keyword ALL indicates that all frames that have a VLAN tag are included. If the VLANID parameter has been omitted or an asterisk(*) is specified, then all frames meet the criteria for this filter. If a VLAN identifier is specified, and the frame does not contain a VLAN tag or does not match the VLAN identifier, then the frame is not traced.

Steps for modifying

As previously indicated, the OSAENTA statements are cumulative for a given OSA adapter, and any subsequent OSAENTA statement processed adds to the filters that are already in effect for that OSA feature. To actually change a value for a given filter, the following options are available:

- Define an OSAENTA statement with a filter value of *, effectively deleting all values for that one filter entirely. Then define subsequent OSAENTA statements with the new filter values.
- Define an OSAENTA statement with the CLEARFILTER parameter, which removes all existing filters, and specify the entire list of filter attributes.

Tip: If the trace is currently enabled, the trace continues to run while each filter is modified or added. This can become an issue when changing a value for a given filter. Because both options involve deleting current filters, more data than you want is being traced during this time. Turn the trace off (define an OSAENTA statement with the OFF option) before changing filter values.

Examples for enabling, disabling, and modifying the OSA feature tracing facility are shown in [“Examples” on page 200](#).

You can also modify existing OSAENTA settings by using the VARY TCPIP,,OSAENTA command. See [z/OS Communications Server: IP System Administrator's Commands](#) for more information. Use the Netstat DEvlinks/-d command to display the results.

Usage notes

- You can use the Netstat DEvlinks/-d command to display the current OSAENTA trace settings.
- When the DATA, FRAMES, or TIME values are exceeded, the stack disables the OSAENTA trace, but this does not happen immediately. Trace records from the OSA feature continue to be recorded until the stack has successfully contacted the adapter to stop the OSAENTA trace.
- To verify that the Ctrace component SYSTCPOT is active for a stack, issue DISPLAY TRACE,COMP=SYSTCPOT,SUB=(*tcpip_procname*).
- To write the data to the external writer, use the MVS TRACE,CT,WTRSTART=*writer_procedure* command to start the writer and the TRACE CT,ON,COMP=SYSTCPOT,SUB=(*tcpip_procname*) command to connect to the writer.
- The last buffer trace data are not written to the external writer until the writer has been disconnected from TCPIP and stopped.
- The TRACE CT,OFF,COMP=SYSTCPOT,SUB=(*tcpip_procname*) command stops the recording of trace data into TCPIP buffers and to the external writer. It does not stop the receipt of trace data from the OSA feature. Issue a TRACE ON command to start recording the trace data into the buffers. To halt the receipt of trace data from the OSA feature, specify the OSAENTA statement with the OFF parameter, or use the V TCPIP,,OSAENTA command with the OFF parameter.
- The OSAENTA trace can have performance implications if sufficient trace filters are not specified before enabling the trace. OSAENTA can reduce the amount of traffic the OSA device can process and the amount of traffic that can be accelerated through that OSA device. Also, host processing to collect the OSAENTA trace records can increase host CPU consumption. Specify sufficient filters to limit the amount of traffic traced to what is necessary for problem diagnosis.

The following differences exist between the OSAENTA and PKTTRACE statements:

- The PKTTRACE statement can collect data for only a single TCP/IP stack. The OSAENTA statement can collect data for other stacks that share the OSA feature.
- Data collection enabled with the PKTTRACE statement starts immediately. The data collection enabled with the OSAENTA statement is not started until the ON parameter is used.
- Each PKTTRACE command or statement is one set of filters. OSAENTA statement filters accumulate across multiple OSAENTA commands or statements.

Examples

The following sample includes several examples of the OSAENTA statement:

```
;
;
; set up the filters to trace for TCP packets on PORT 5003 with a source
; or destination
; IP address of 9.67.116.124 over MAC address 000084576893
OSAENTA PORTNAME=OSA4 PROTO=TCP IP=9.67.116.124 PORTNUM=5003
OSAENTA PORTNAME=OSA4 MAC=000084576893
; activate the tracing (the trace will self-deactivate after 20,000 frames)
OSAENTA PORTNAME=OSA4 ON FRAMES=20000
;
; deactivate the tracing
OSAENTA OFF PORTNAME=OSA4
;
; Reactivate the tracing for another 20,000 frames
OSAENTA ON PORTNAME=OSA4
;
; Modify tracing to change a port filter
OSAENTA PORTNAME=OSA4 PORTNUM=*
OSAENTA PORTNAME=OSA4 PORTNUM=21
;
; Change the parameters (add an IP address)
OSAENTA IP=9.67.116.125 PORTNAME=OSA4
;
; Set up tracing for a new problem on OSA5
; trace frames on VLAN 192 or 193 with an IP address 9.37.124.00 to .255 or
; 9.37.125.00 to .255 or
; 9.37.126.00 to .255
OSAENTA PORTNAME=OSA5 ABBREV=480 TIME=5
VLANID=192 IP=9.37.124/24
OSAENTA PORTNAME=OSA5 IP=9.37.125/24
OSAENTA PORTNAME=OSA5 VLANID=193 IP=9.37.126/24
;
; Now activate the trace with the new filters for 5 minutes
OSAENTA ON PORTNAME=OSA5
;
; Reset the VLANID filter and restart tracing for another 5 minute interval
OSAENTA ON PORTNAME=OSA5 VLANID=*
```

PKTTRACE statement

Use the PKTTRACE statement to control the packet tracing facility in TCP/IP. You can use this statement to select IP packets as candidates for tracing and subsequent analysis.

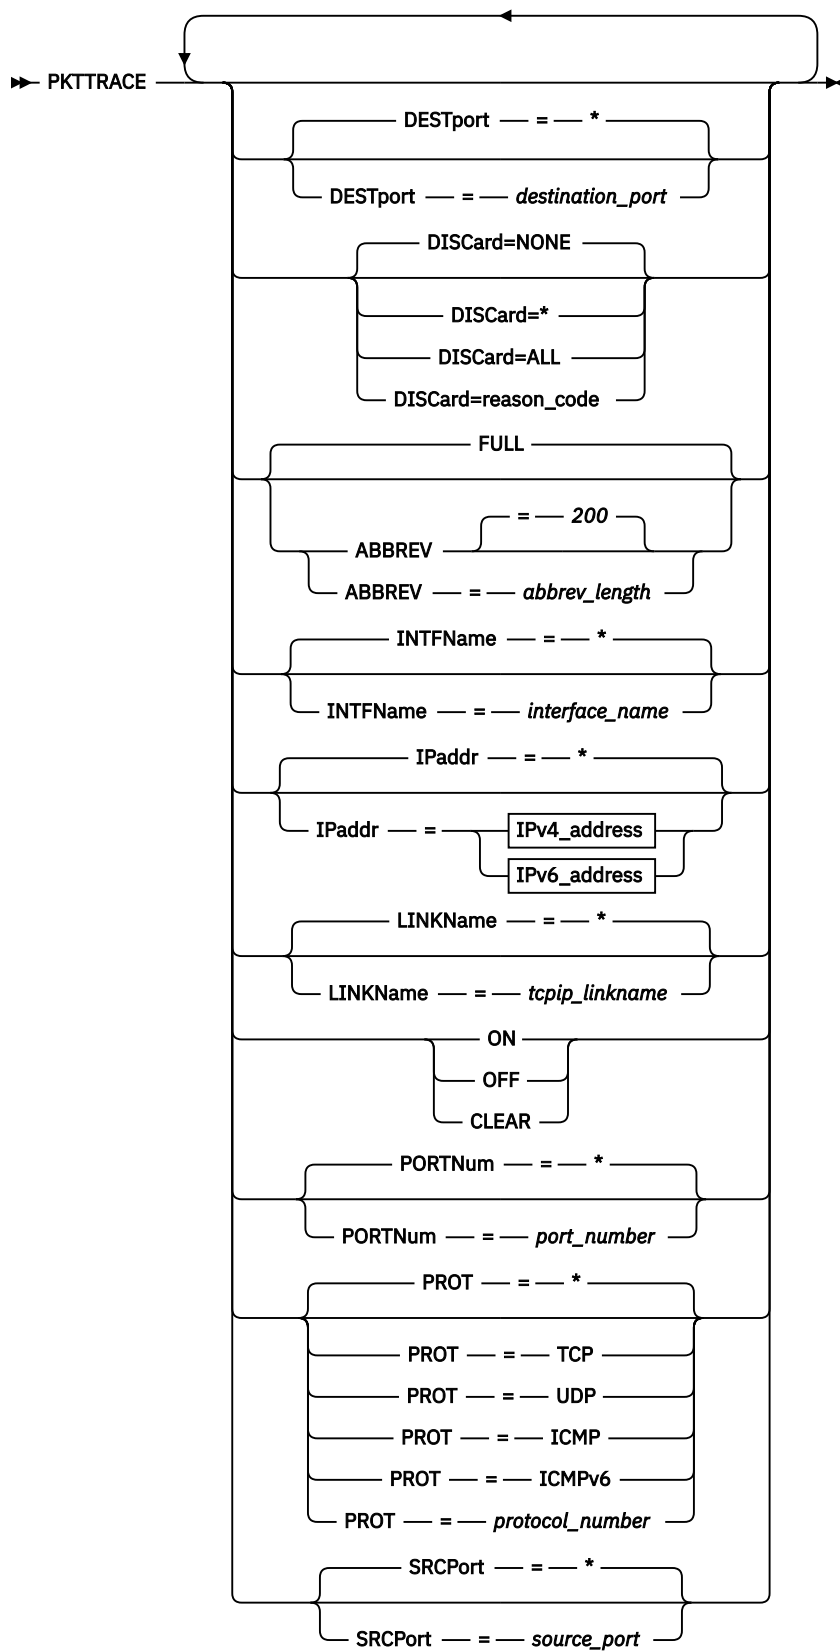

Restriction: An IP packet must meet all the conditions that are specified on the statement for it to be traced. But SMC-R LLC traffic is always traced, regardless of the specified conditions on the PKTTRACE statement.

The PKTTRACE statement consists of two parts. The first part defines to TCP/IP the network interfaces that are to be traced and characteristics of how they are to be traced. The second part turns packet tracing ON or OFF or CLEARs packet trace settings for the interfaces specified on prior PKTTRACE statements or for a single interface if the LINKName/INTFName parameter is used.

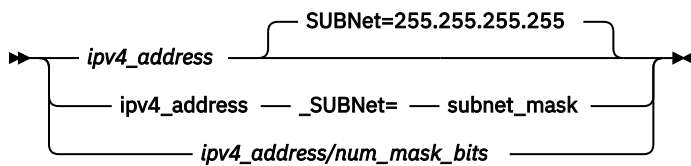

Packet traces are recorded externally using the TRACE command CTRACE writer instead of GTF. See [z/OS Communications Server: IP Diagnosis Guide](#) for information about the steps required to perform an [IP packet trace](#).

Syntax

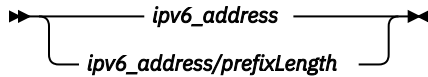

Tip: Specify the parameters for this statement in any order.

IPv4_address

IPv6_address

Parameters

ABBREV

Specifies that a truncated portion of the IP packet is to be traced. You can specify a length in the range 0 - 65 535, or use the default of 200. The ABBREV parameter can be used to reduce the volume of data stored in the trace file.

The protocol headers are always included, even if they exceed the ABBREV value.

CLEAR

Disables packet tracing for the interfaces specified and removes the characteristics defining how they should be traced.

DESTPORT

Specifies a port number that is compared with the destination port of inbound and outbound packets. The port number is an integer in the range 1 - 65 535. If the destination port of a packet is the same as the specified port number, the packet is traced. This comparison is performed only for packets using the TCP or UDP protocol; packets using other protocols are not traced. If the DESTPORT parameter is omitted, and the PORTNUM parameter is also omitted, or an asterisk (*) is specified for the DESTPORT parameter, the destination port of packets is not checked.

IPSec Encapsulating Security Payload (ESP) packets cannot be traced by using the port number because the TCP or UDP headers are encrypted.

DISCARD

Specifies the IP packet discard reason code for the packets that should be traced. All IP packets have a discard reason code associated with them, which is typically set to 0. When the TCP/IP stack discards a packet, a specific discard reason code is set in this field. See the IP discard reason codes information in *z/OS Communications Server: IP and SNA Codes* for a list of all the discard reason codes. Typically, the TCP/IP stack does not trace discarded packets. You must specify a DISCARD value other than NONE to trace discarded packets. Valid values for DISCARD are:

The DISCARD parameter is not applied to the selection of packets. All packets are traced.

ALL

Specifies that IP packets with a nonzero discard reason code should be traced. Specifying this value results in tracing only discarded packets.

NONE

Specifies that only IP packets that were not discarded should be traced. This is the default value.

reason_code

Specifies that only IP packets with the specified discard *reason_code* value should be traced. The *reason_code* value is a number in the range of 4 096 - 20 479. You can also specify a value of 0, which is the equivalent of DISCARD=NONE.

Tips:

- A packet can be traced twice, once at the lower level IP layer when a packet arrives (with a discard reason code of 0), and again as a discarded packet in an upper level protocol layer of TCP/IP.

- You can use one packet trace profile statement per discard reason code. You can also specify a packet trace statement with DISCARD=ALL to trace all packets that are discarded. The other specified parameters are used to further select which discarded packets are traced. For example, use the following code to collect packets with discard reason code 4138 on all TCP or UDP packets with PORT number 20:

```
PKTTRACE ON,DISCARD=4138,PORTNUM=20
```

- Specifying the SRCPORT, DESTPORT, IPADDR, PORTNUM or PROTOCOL parameters might prevent malformed packets from being traced.

FULL

Specifies that the entire IPADDR packet is to be traced.

IPADDR

Specifies an IPv4 or IPv6 address that is compared with both the source and destination addresses of inbound and outbound packets. If either the source or destination address of a packet matches the specified IP address, the packet is traced. If the IPADDR option is omitted, or an asterisk (*) is specified, then all IP addresses are traced.

Guidelines:

- If an IPv6 address is specified, an optional prefix length in the range 1 - 128 is allowed. The default prefix length is 128.
- If an IPv4 address is specified, the /num_mask_bits value is allowed.

/num_mask_bits

Specifies a numeric mask in the range 1 - 32.

/prefixLength

Specifies a numeric prefix length in the range 1 - 128.

LINKNAME|INTFNAME

The LINKNAME and INTFNAME parameters are interchangeable. They specify the name of the network interface defined on a preceding LINK or INTERFACE statement. If the LINKNAME or INTFNAME parameter is omitted or an asterisk (*) is specified for either parameter, the PKTTRACE parameters apply to all IPv4 and IPv6 interfaces prior to this statement.

To facilitate defining packet tracing when many interfaces are involved, use the PKTTRACE statement with the LINKNAME=* or INTFNAME=* option to define packet tracing characteristics for the majority of the interfaces. Then use individual PKTTRACE statements with specific LINKNAME or INTFNAME parameters for each interface that must be defined differently from the majority or interfaces.

The PKTTRACE statement must appear after a valid LINK or INTERFACE statement for the link or interface in the PROFILE.TCPIP data set.

OFF

Disables packet tracing for the specified interfaces and removes the characteristics defining how they should be traced.

If LINKNAME=* or INTFNAME=* and all other parameters are defaults, all trace structures are deactivated and removed from all existing IPv4 and IPv6 interfaces.

If LINKNAME=* or INTFNAME=* and PROT=UDP, all trace structures for all resources are analyzed; any matches are removed. If no trace structures remain, trace is deactivated for that resource.

If LINKNAME=*link_name* or INTFNAME=*interface_name* and there are no other parameters, all trace structures for *link_name/interface_name* are deactivated and removed.

If LINKNAME=*link_name* and IP=127.0.0.1, or INTFNAME=*interface_name* and IP:::1, then that particular trace structure is removed if it is found. If there is only one trace structure, then that structure is removed and trace is deactivated for that resource.

ON

Turns on packet tracing, clears all settings previously defined and refreshes just the default settings.

If you use LINKNAME=* or INTFNAME=* and all other parameters are defaults, even if the defaults are specified, the command results replace any existing trace structures for all existing IPv4 and IPv6 interfaces.

If you use LINKNAME=*link_name* or INTFNAME=*interface_name* and another nondefault parameter, the command results are added to any existing trace structures. However, if the existing trace structure for *link_name/interface_name* is all defaults, the existing trace structures are discarded.

PORTNUM

Specifies a port number that is compared with the destination and source port of inbound and outbound packets. You can use this parameter instead of using the SRCPORT and DESTPORT parameters. The port number is an integer in the range 1 - 65 535. If the destination or source port of a packet is the same as the specified port number, the packet is traced. This comparison is performed only for packets using the TCP or UDP protocol; packets using other protocols are not traced. If the PORTNUM parameter is omitted and the SRCPORT and DESTPORT parameters are also omitted, then the port numbers of packets are not checked. If an asterisk (*) is specified, packets of any protocol and any destination or source port number are traced.

Guideline: SRCPORT and DESTPORT parameters should not be specified on the same PKTTRACE statement as the PORTNUM parameter. When the PORTNUM parameter is specified after DESTPORT or SRCPORT parameters, the DESTPORT and SRCPORT parameters are ignored.

Restriction: IPsec Encapsulating Security Payload (ESP) packets cannot be traced by port number because the TCP or UDP headers are encrypted.

PROT

Specifies the protocol type to be traced. This can be specified as one of the literals TCP, UDP, ICMP, or ICMPV6, or as a number between 1 and 255 (ICMP=1, TCP=6, UDP=17, ICMPV6=58, and RAW=255). If the PROT parameter is omitted or an asterisk (*) is specified, packets of any protocol are traced.

SRCPORT

Specifies a port number that is compared with the source port of inbound and outbound packets. The port number is an integer in the range 1 - 65535. If the source port of a packet is the same as the specified port number, the packet is traced. This comparison is performed only for packets using the TCP or UDP protocol; packets using other protocols are not traced. If the SRCPORT parameter is omitted, and the PORTNUM parameter is also omitted, or an asterisk (*) is specified for the SRCPORT parameter, the source port of packets is not checked.

IPsec Encapsulating Security Payload (ESP) packets cannot be traced by port number because the TCP or UDP headers are encrypted.

SUBNET

Specifies a subnet mask that applies to the host and network portions of the IP address specified on the accompanying IPADDR parameter. The subnet mask must be specified in dotted decimal notation and must be specified in conjunction with the IPADDR parameter. The default is 255.255.255.255.

Steps for modifying

You can activate tracing at any time by executing the VARY TCPIP,,OBEYFILE command with a data set that contains PKTTRACE statements. However, the interface names specified on the PKTTRACE statements must already be defined. For example:

```
PKTTRACE ON, LINKNAME=*  
LINK ...  
DEVICE ...
```

In this example, the trace is done only for the LOOPBACK interface.

For more information about changing PKTTRACE parameters, see the descriptions for the ON and OFF parameters for “[PKTTRACE statement](#)” on page 200.

You can also modify existing PKTTRACE settings by using the VARY TCPIP,,PKTTRACE command. See [z/OS Communications Server: IP System Administrator's Commands](#) for more information.

To trace all the packets for a particular application port, enter two PKTTRACE commands:

```
PKTTRACE ON,DESTport=21
PKTTRACE ON,SRCport=21
```

The two commands capture all the packets received and all the packets sent for a particular port. If other options are specified, then they should be the same on both commands.

Use the Netstat DEvlinks/-d command to display the results. An IP packet is traced according to the first trace structure that the packet matches.

Statement dependency

- INTFName and LINKName are mutually exclusive. An error message is displayed if both are coded.
- The num_mask_bits and SUBNET= are mutually exclusive. An error message is displayed if both are coded.
- IP=* implies IP=0.0.0.0 and SUBNET=255.255.255.255.
- The IP address and subnet mask pair specified must be in the same network.
- Tracing is not done for packets whose destination and source IP address match. However, tracing is always done for packets using a loopback interface.

Usage notes

- Multiple PKTTRACE statements can be included in the PROFILE.TCPIP; the results are cumulative.
- If a keyword on a given statement is specified multiple times, the last value specified is used. If an option appears more than once on a statement, the value associated with the last occurrence of the option is used.
- If you do not specify any options on the PKTTRACE statement, all packets through all devices are traced except for discarded packets. The default is DISCARD=NONE.
- If an error is found while parsing the PKTTRACE statement, an error message is generated, the parameter in error is ignored, and the rest of the statement is parsed. If an error is produced by an incorrect ABBREV value, the ABBREV value is changed to the default.
- Each defined interface has an associated trace profile. The trace profile stores the values of each of the trace options for the interface. When you create or reset a trace profile for an interface using the CLEAR option, the trace profile is set to the default values for the trace options as follows:

PROT

All protocols

IPADDR

All IP addresses

SUBNET

No checking

SRCPORT

No checking

DESTPORT

No checking

FULL

Trace of the whole IP packet

Examples

The following sample includes several examples of the PKTTRACE statement:

```
; CTC Device and Link
DEVICE CTC1      CTC      D00
LINK  CTCD00     CTC      1  CTC1
```

```

;
; CTC Device and Link
DEVICE CTC2      CTC      D02
LINK   CTCD02    CTC  1   CTC2
;
; CTC Device and Link
DEVICE CTC3      CTC      D04
LINK   CTCD04    CTC  1   CTC3
;
; start pkttrace
PKTTRACE ON LINKNAME=*
;
; set defaults for all links not specified below
PKTTRACE
; set for CTCD00
PKTTRACE FULL LINKNAME=CTCD00 PROT=* IP=* SRCPORT=* DESTPORT=*
; set for CTCD02
PKTTRACE ABBREV LINKNAME=CTCD02 PROT=TCP IP=9.67.116.124
SRCPORT=5000 DESTPORT=161
; set for CTCD04
PKTTRACE ABBREV=1 LINKNAME=CTCD04 PROT=UDP IP=9.67.116.124
SUBNET=255.255.255.255 SRCPORT=161 DESTPORT=5000

```

PORT statement

Use the PORT statement to reserve a port for one or more specified job names or to control application access to unreserved ports.

Syntax

Rule: The PORT parameters and options (for example, NOAUTOLOG, DELAYACKS) must be specified in the order in which they appear on the following syntax diagram.

➡ PORT ➡

Options

Parameters

num

The number of the port to be reserved. The same port number can appear in more than one PORT statement with different users or more than once in the same PORT statement. This port cannot appear in a range specified by the PORTRANGE statement. If a PORTRANGE statement including this port number is specified prior to this statement, this port is ignored. If the PORTRANGE statement follows this statement, the PORTRANGE statement is ignored. An error message is generated in either case. *num* is a value in the range 1 - 65535.

Requirement: For z/OS UNIX applications that are invoked by INETD, ensure that the port number defined for the application in the /etc/services file is the same as the port number reserved for the application on the PORT statement.

UNRSV

This value indicates any unreserved port (any port number that is in the range 1 - 65535 that has not been reserved by a PORT or PORTRANGE statement).

Use PORT UNRSV statements to indicate which applications or users are permitted to access application-specified unreserved ports. PORT UNRSV statements control access to all unreserved ports in the range 1 - 65535 unless RESTRICTLOWPORTS is configured; however, when RESTRICTLOWPORTS is configured, PORT UNRSV statements control access to unreserved ports only above port 1023. For UDP, access control is applied when an application issues a bind to a particular

port number to establish a local port. For TCP, access control is applied depending on the value of the WHENBIND or WHENLISTEN parameter.

If neither DENY nor the SAF keyword is specified, an application that matches the protocol and specified job name [the job name can be an asterisk (*)] on a PORT UNRSV statement can access unreserved ports. If DENY is specified, all applications are denied access to unreserved ports for the specified protocol. If the SAF keyword is specified, applications that match the PORT UNRSV statement must also have user access to the SAF SERVAUTH resource which is indicated by the SAF keyword, to be permitted to access an unreserved port.

Results:

- When no PORT UNRSV statements are configured for the socket protocol that is being used, all applications are allowed access to the unreserved ports unless prevented by TCPCONFIG or UDPCONFIG RESTRICTLOWPORTS or by GLOBALCONFIG EXPLICITBINDPORTRANGE. This is the default.
- When TCPCONFIG or UDPCONFIG RESTRICTLOWPORTS is configured for the access protocol that is being used, PORT UNRSV access control applies only to unreserved ports above port 1023.
- If any PORT UNRSV statements are configured for a protocol, access is determined by the PORT UNRSV statement whose specified job name most closely matches the application's job name. If the application's *jobname* does not match any of the PORT UNRSV statements, the application's access to unreserved ports is denied for that protocol.
- PORT UNRSV statements control access to nonzero, unreserved ports that are specified on explicit binds. Access to unreserved ports that are assigned by the stack is not affected.

Guideline: In a Common INET (CINET) environment with multiple stacks and no established stack affinity, an explicit bind to port 0 is converted to a bind to a specific port in the CINET range. If you have not reserved the ports in your CINET range for *jobname* OMVS, the explicit bind to port 0 is treated as an explicit bind to an unreserved port.

RESERVED

Indicates the port is not available for use by any user. Use RESERVED to lock certain ports. This is optional and valid for TCP or UDP protocols.

jobname

Specifies the MVS job name that can use the specified port or any unreserved port in the case of a PORT UNRSV statement. You can specify the *jobname* value as one of the following values:

- The 1 - 8 character name of the job that is required to use the port.
- A 1 - 8 character value including wildcard characters. The following wildcard characters are supported:
 - An asterisk (*) can be used in any position in the value to indicate zero or more unspecified characters.
 - A question mark (?) can be used in any position in the value to indicate a single unspecified character.

For example, the job name *searchee* matches a PORT statement whose job name value is **ar?he**. But the job name *searhee* does not match a PORT statement whose job name value is **ar?he**.

- An asterisk (*) wildcard character. Specify an asterisk as the *jobname* value to reserve a port without specifying a particular job name. You can use an asterisk if you do not know the exact job name or if you want to allow different applications to serially bind to the port.
- A 1 - 7 character prefix that is followed by an asterisk wildcard value. This specification enables all job names that match the prefix to access the port.

For UDP, only one job name can be associated with a particular port. For TCP, the same port can be reserved multiple times for different job names. This can be useful if you have different servers with different job names that need access to the same port. For PORT UNRSV statements, both TCP and UDP can have multiple statements with different job names.

For multiple TCP reservations for the same port, or for multiple PORT UNRSV statements for the same protocol, the TCP/IP stack searches these PORT statements for the closest match (if any) to the application's job name. If you specified the job name using a wildcard on more than one of these statements, the TCP/IP stack matches the application job name to a PORT statement *jobname* value using the most specific value first and the least specific value (or value *, if it was specified) last.

Restriction: To reserve a port that is to be monitored by AUTOLOG, the *jobname* name must exactly match (no wildcards) the *jobname* name on the AUTOLOG statement.

The environment in which the application is run determines the job name to be associated with a particular client or server application.

The following list explains how to determine the *jobname* value given the environment in which the application is run:

- Applications run from batch use the batch job name.
- Applications started from the MVS operator console use the started procedure name as the job name.
- Applications run from a TSO user ID use the TSO user ID as the job name.
- Applications run from the z/OS shell normally have a job name that is the logged on user ID plus a one-character suffix.
- Authorized users can run applications from the z/OS shell and use the _BPX_JOBNAME environment variable to set the job name. In this case, the value specified for the environment variable is the job name.
- Use the name of the started JCL procedure for the UNIX System Services kernel address space to enable applications (except for applications using the Pascal API) to bind to the port. This name is typically OMVS unless a different name is explicitly specified in the STARTUP_PROC parameter of the BPXPRMxx parmlib member.
- z/OS UNIX applications started by INETD use the *jobname* of the INETD server.
- Use the name of the VTAM started task for the UDP ports that are to be used for Enterprise Extender (EE) network connections.

Restriction: The VTAM job name cannot include a wildcard character when it reserves EE UDP ports.

Reserved Port Options:

NOAUTOLOG

Tells the TCP/IP address space *not* to restart the server if it was stopped previously. Otherwise, the default is to restart the server if it was stopped previously. If the application associated with the job name is an AUTOLOG started procedure, and the port is inactive (for TCP connections, the procedure must have a socket open to that port in the LISTEN state; for UDP connections, the procedure must have a socket open to that port), then AUTOLOG assumes that the procedure is hung; it cancels and restarts it every five minutes. Use NOAUTOLOG to prevent this from occurring. See [“AUTOLOG statement” on page 16](#) for more information.

DELAYACKS | NODELAYACKS

DELAYACKS

Delays transmission of acknowledgments when a packet is received with the PUSH bit on in the TCP header. The DELAYACKS parameter on the PORT statement affects only connections that use this port. This is the default, but the behavior can be overridden by specifying the NODELAYACKS parameter on the TCP/IP stack TCPCONFIG profile statement, or on any of the following statements used to configure the route used by the TCP connection:

- The TCP/IP stack BEGINROUTES profile statement
- The Policy Agent RouteTable statement
- The OMPROUTE configuration statements

NODELAYACKS

Specifies that an acknowledgment is returned immediately when a packet is received with the PUSH bit on in the TCP header. The NODELAYACKS parameter on the PORT statement affects only connections that use this port. Specifying NODELAYACKS on the PORT statement overrides the specification of the DELAYACKS parameter on the TCP/IP stack TCPCONFIG profile statement or on any of the following statements used to configure the route used by the TCP connection:

- The TCP/IP stack BEGINROUTES profile statement
- The Policy Agent RouteTable statement
- The OMPROUTE configuration statements

SHAREPORT

Required when reserving a port to be shared across multiple listeners on the same interface. When SHAREPORT is specified, TCP/IP allows multiple listeners to listen on the same combination of port and IP address.

As incoming client connections arrive for this port and IP address, TCP/IP distributes them across the listeners. Specification of this keyword causes incoming connection requests for the port to be distributed among the listeners using a weighted round-robin distribution method based on the servers' accept Efficiency Fractions (SEFs) of the listeners sharing the port. The SEF is a measure, calculated at intervals of approximately one minute, of the efficiency of the server application in accepting new connection requests and managing its backlog queue. Alternatively, SHAREPORTWLM can be coded instead; SHAREPORTWLM changes the connection distribution algorithm.

If the same port is reserved for multiple job names, SHAREPORT or SHAREPORTWLM needs to be specified on only one instance of the port reservation. SHAREPORT and SHAREPORTWLM are valid only for TCP ports. The last setting of either SHAREPORT or SHAREPORTWLM is used for all TCP/IP servers that use that port.

SHAREPORTWLM

Required when reserving a port to be shared across multiple listeners on the same interface. When SHAREPORTWLM is specified, TCP/IP allows multiple listeners to listen on the same combination of port and IP address.

The SHAREPORTWLM option can be used instead of SHAREPORT. Like SHAREPORT, SHAREPORTWLM causes incoming connections to be distributed among a set of TCP listeners; however, unlike SHAREPORT, the listener selection is based on WLM server-specific recommendations, modified by the SEF values for each listener. WLM server-specific recommendations are acquired at intervals of approximately 1 minute from the Work Load Manager and reflect the listener's capacity to handle additional work.

If the same port is reserved for multiple job names, SHAREPORT or SHAREPORTWLM needs to be specified on only one instance of the port reservation. SHAREPORT and SHAREPORTWLM are valid only for TCP ports. The last setting of either SHAREPORT or SHAREPORTWLM is used for all TCP/IP servers that use that port.

Result: zAAP and zIIP processor capacity is automatically included when the SHAREPORTWLM parameter is specified and all systems in the sysplex are V1R9 or later.

BIND *ipaddr*

Associates a job name with the IP address, *ipaddr*. When a job with the designated name binds to the IPv4 INADDR_ANY address, or to the IPv6 unspecified address (in6addr_any), the bind is intercepted and converted to a bind to the IP address specified by *ipaddr*. Subsequent bind processing occurs as though the server instance had originally issued the bind to the IP address *ipaddr*.

You can specify either an IPv4 address (in dotted decimal notation) or an IPv6 address (in hexadecimal notation). IPv4-mapped IPv6 addresses and IPv6 addresses with the reserved prefix ::/96 are not supported.

Rule: The BIND *ipaddr* parameter does not apply to the PORTRANGE statement.

Guidelines:

- When you are using the BIND parameter with IPv6 addresses, you should use only manually configured addresses, because autoconfigured addresses might change when the stack is recycled.
- If the IP address specified on the BIND parameter is also specified in a VIPARANGE statement subnet, then VIPARANGE security verification might occur to determine whether an application can create the dynamic VIPA (DVIPA). For information about [defining a security profile for binding to DVIPAs in the VIPARANGE statement](#), see [z/OS Communications Server: IP Configuration Guide](#).

SAF *resname*

Indicates that the port is reserved for users that have READ access to the RACF resource

```
EZB.PORTACCESS.sysname.tcpname.resname
```

where

- EZB.PORTACCESS is constant
- *sysname* is the value of the MVS &SYSNAME. system symbol
- *tcpname* is the name of the procedure used to start the TCP stack
- *resname* is the 1-8 character value following the SAF keyword

Restriction: You can not specify a 1-character value of 0 (zero) for *resname*.

If the SAF keyword is specified and a user tries to bind to the port and is not allowed access to the resource, the BIND socket call fails.

Tip: The SAF keyword is ignored when VTAM opens a UDP port for Enterprise Extender (EE) network connections. However, it can still be used to prevent other address spaces that are using the same name as the VTAM started task from opening the port.

This is optional and valid for TCP or UDP protocols.

If the *jobname* parameter is specified as an asterisk (*), any user ID that is RACF-permitted to the resource specified by the *resname* value is allowed to bind to the port specified by the value; APF or superuser authority is not required.

This permits multiple users access to the protected port. However, the stack allows only one user to actually BIND to the port at a time. Use SHAREPORT or SHAREPORTWLM to override this behavior for TCP ports.

Guideline: If an application binds to an IP address that is also specified in a VIPARANGE statement subnet, then additional security verification might occur to determine whether the application can create the dynamic VIPA (DVIPA). This additional verification might occur whether the application explicitly binds to the DVIPA address or whether the application binds to the unspecified address and is converted to the DVIPA address using the BIND parameter. For information about [defining a security profile for binding to DVIPAs in the VIPARANGE statement](#), see [z/OS Communications Server: IP Configuration Guide](#).

SMC | NOSMC

Configuration of these parameters overrides configuration of the AUTOSMC monitoring function for the servers that are associated with the reserved port. The AUTOSMC monitoring function is the default option for the GLOBALCONFIG SMCGLOBAL parameter. However, the default AUTOSMC monitoring is activated only when you enable or disable SMC support on the GLOBALCONFIG profile statement.

- To enable or disable Shared Memory Communications over Remote Direct Memory Access (SMC-R) support, specify the SMCR or NOSMCR parameters on the GLOBALCONFIG profile statement.
- To enable or disable Shared Memory Communications - Direct Memory Access (SMC-D) support, specify the SMCD or NOSMCD parameters on the GLOBALCONFIG profile statement.

For more information, see [Use the AUTOSMC monitoring function in z/OS Communications Server: IP Configuration Guide](#).

NOSMC

Indicates that Shared Memory Communications (SMC) is not permitted for inbound TCP connections that use this port. This setting overrides the SMCGLOBAL AUTOSMC parameter on the GLOBALCONFIG profile statement and ensures that inbound TCP connections to this port do not use SMC. NOSMC is valid only for TCP ports.

SMC

Indicates that the stack attempts to use SMC for inbound TCP connections that use this port. This parameter is required only when you use the SMCGLOBAL AUTOSMC parameter on the GLOBALCONFIG profile statement and you want to ensure that the stack attempts to use SMC for inbound TCP connections. SMC is valid only for TCP ports.

Unreserved Port Options:

SAF *resname*

Indicates that binding to, or listening on, any unreserved port is restricted to users that are permitted to the specified SAF SERVAUTH resource. See the description of the SAF parameter for more information.

DENY

DENY indicates that port access should be denied. DENY can be specified only for unreserved ports (on the PORT UNRSV statement) and only when the specified jobname is an asterisk (*).

A PORT UNRSV *protocol* * DENY statement is needed only if no other PORT UNRSV statements are configured for the specified protocol and you want to prevent all access to unreserved ports using that protocol.

WHENLISTEN

WHENLISTEN indicates that port access control is targeted to TCP applications that are acting as servers (that is, applications able to accept incoming client TCP connections) that issue an explicit bind to a user-specified unreserved port. Permission to use the unreserved port is determined when a TCP listen is issued. If a listen is not issued, no access control check is made. The WHENLISTEN parameter is not available for the UDP protocol, and it is the default for the TCP protocol.

Rule: Every PORT UNRSV statement for the TCP protocol must use the same access control option. You cannot specify , or default to, the WHENLISTEN parameter on some statements and specify the WHENBIND parameter on other statements.

WHENBIND

WHENBIND indicates that permission to use an unreserved port is determined when an explicit bind to a specific local port is issued. This is the default, and only option, for the UDP protocol, and it can affect UDP applications that bind to a specific local port. If the WHENBIND parameter is specified for the TCP protocol, it can affect TCP client applications that bind to a specific local port for outbound connections.

Rule: Every PORT UNRSV statement for the TCP protocol must specify, or default to, the same access control option. You cannot specify the WHENLISTEN parameter on some statements and specify the WHENBIND parameter on other statements.

Steps for modifying

To change a parameter value, you must delete the existing PORT statement by using the DELETE PORT statement, then redefine with the new PORT statement.

Examples

The following example was used for test configuration and is provided here for illustration only. The sample profile, SEZAINST(SAMPPROF), contains the most current assignments.

```
PORT
  7 UDP MISC SERV          ; Miscellaneous Server - echo
  7 TCP MISC SERV          ; Miscellaneous Server - echo
  9 UDP MISC SERV          ; Miscellaneous Server - discard
```

```

    9 TCP MISC SERV      ; Miscellaneous Server - discard
    19 UDP MISC SERV     ; Miscellaneous Server - chargen
    19 TCP MISC SERV     ; Miscellaneous Server - chargen
    20 TCP * NOAUTOLOG   ; FTP Server
;   20 TCP * NOAUTOLOG SAF FTPDATA ; FTP Server
    21 TCP FTPD1         ; FTP Server
    23 TCP TN3270        ; Telnet 3270 Server
;   23 TCP INETD1 BIND 9.67.113.3 ; z/OS UNIX Telnet server
    111 TCP PORTMAP      ; Portmap Server (SUN 3.9)
    111 UDP PORTMAP      ; Portmap Server (SUN 3.9)
;   111 TCP PORTMAP1     ; Unix Portmap Server (SUN 4.0)
;   111 UDP PORTMAP1     ; Unix Portmap Server (SUN 4.0)
    123 UDP SNTPD        ; Simple Network Time Protocol Server
    135 UDP LLBD         ; NCS Location Broker
    161 UDP OSNMPD       ; SNMP Agent
    389 TCP LDAPSrv      ; LDAP Server
    443 TCP HTTPS        ; http protocol over TLS/SSL
    443 UDP HTTPS        ; http protocol over TLS/SSL
;   500 UDP IKED         ; CS IKE daemon
    512 TCP RXSERV       ; Remote Execution Server
    514 TCP RXSERV       ; Remote Execution Server
;   512 TCP * SAF OREXECd ; z/OS UNIX Remote Execution Server

    751 UDP ADM@SRV      ; Kerberos Admin Server
;  1700 TCP PAGENT NOAUTOLOG ; Policy Agent pagentQosListener port
;  1701 TCP PAGENT NOAUTOLOG ; Policy Agent pagentQosCollector port
    3000 TCP CICS TCP     ; CICS Socket
    3389 TCP MSYSLDAP     ; LDAP Server for Msys
;  4159 TCP NSSD         ; CS NSS daemon
    4500 UDP IKED        ; CS IKE daemon
; 16310 TCP PAGENT NOAUTOLOG ; Policy Agent server listener port
;

```

The following examples control application access to unreserved ports:

- To deny all TCP explicit binds to an unreserved port, add the following statement to your profile:

```
PORT UNRSV TCP * DENY WHENBIND
```

- To allow TCP explicit binds to an unreserved port but deny all TCP listens on an unreserved port, add the following statement to your profile:

```
PORT UNRSV TCP * DENY WHENLISTEN
```

- To deny all TCP listens on an unreserved port, except for applications that match *jobname* value ABC*, add the following statement to your profile:

```
PORT UNRSV TCP ABC* WHENLISTEN
```

Guideline: If the ports that applications ABC* are accessing are predictable, you should use PORT reservation statements for those specific ports instead of using the PORT UNRSV statement.

- To deny all TCP listens on an unreserved port, except for application MYAPP1 and all users permitted to EZB.PORTACCESS.sysname.tcpname.GENERIC, add the following statements to your profile:

```
PORT UNRSV TCP MYAPP1
PORT UNRSV TCP * SAF GENERIC
```

- To deny all UDP explicit binds to an unreserved port, except for users permitted to EZB.PORTACCESS.sysname.tcpname.GENERIC, add the following statement to your profile:

```
PORT UNRSV UDP * SAF GENERIC
```

Usage notes

- If there are no PORT UNRSV statements configured for this stack, any user can use a port that is not reserved in this list or that is not reserved with the PORTRANGE statement. If you have TCP/IP hosts in your network that use ports in the range 1 - 1023 for privileged applications, you should reserve them with this statement, the PORTRANGE statement, or the RESTRICTLOWPORTS parameter on the TCPCONFIG or UDPCONFIG statements.
- If an application attempts to access a specific port by explicitly binding for UDP, by explicitly binding, or listening for TCP, and no PORT or PORTRANGE statement is found that matches that port and protocol (that is, the port is unreserved for that protocol), then a check is made for PORT UNRSV statements. The following list shows the possible results:
 - If there are no PORT UNRSV statements for that protocol, the access is allowed.
 - If there are any PORT UNRSV statements for the protocol, a search is made for the most specific match to the application's job name.
 - If a match is found, the access is allowed unless the closest matching PORT UNRSV statement contains the DENY keyword, or if it contains the SAF keyword and the user is not permitted to the specified SAF resource.
 - If no matching PORT UNRSV statement is found, the access is denied.
- For z/OS UNIX applications, you can reserve a port by specifying the job name of the application or you can use the name of the started JCL procedure for the z/OS UNIX kernel address space to enable any application (except applications using the Pascal API) to bind to the port. This name is typically OMVS unless a different name is explicitly specified in the STARTUP_PROC parameter in the BPXPRMxx parmlib member. See [z/OS MVS Initialization and Tuning Reference](#) for more details about the STARTUP_PROC parameter.
- If syslogd is configured to accept log data from remote syslogd clients, the ports defined for the syslog service in your services file or data set (for example, /etc/services) must also be reserved with the PORT statement. For example, if UDP port 514 and TCP port 6514 are defined to receive log data from remote syslogd clients, you must include the following PORT statements:

```
PORT
  514 UDP OMVS      ; syslogd Server
  6514 TCP OMVS     ; syslogd Server
```

Guideline: Instead of OMVS, you can also use the job name of the syslog daemon on this port reservation statement. If your syslog daemon's job name is SYSLOGD1, you can specify:

```
PORT  514  UDP  SYSLOGD1
      6514 TCP  SYSLOGD1
```

- If you want SNMP OSA Management support, see [z/OS Communications Server: IP Configuration Guide](#) for more information about the PORT statement.
- The NOSMC option is enforced during TCP bind() processing. To allow servers that bind to a port that is configured with the NOSMC option to use SMC communications, you need to perform the following steps:
 1. Delete the existing port reservation by using the VARY TCPIP,,OBEYFILE command with a data set that contains a DELETE PORT statement.
 2. Create a reservation for the port by using the VARY TCPIP,,OBEYFILE command with a data set that contains a PORT statement without the NOSMC parameter.
 3. Stop and restart the servers that use the port.

PORTRANGE statement

Use the PORTRANGE statement to reserve a range of ports for specified user IDs, procedures, or job names. The PORTRANGE statement can also specify other options that apply to all ports in the range.

Rule: The portrange options (NOAUTOLOG, DELAYACKS, and so on) must be specified in the same order as they appear on the following syntax diagram.

Syntax

PortRange Access Specifications

Options

Parameters

1st_port

The starting port for a range of ports to reserve. The same port number cannot appear in multiple PORTRANGE statements, nor can the port be specified on both PORTRANGE and PORT statements. If the port is specified on a PORT statement prior to this statement, this port range is ignored. If the port is specified on a PORT statement that follows this statement, the port in the PORT statement is ignored. An error message is generated in either case. *1st_port* is a value in the range 1 - 65535.

If the *1st_port* and *num_ports* values that are specified result in a range of ports that exceeds the maximum port number of 65535, the ports up to 65535 are reserved and those greater than 65535 are ignored.

num_ports

The number of ports to reserve. The ports reserved cannot overlap other ranges specified by a PORTRANGE statement. No ports within this range can be specified on a PORT statement. If the port is specified on a PORT statement prior to this statement, this port range is ignored. If the port is specified on a PORT statement that follows this statement, the port in the PORT statement is ignored. An error message is generated in either case. *num_port* is a value in the range 1 - 65535.

If the *1st_port* and *num_ports* values that are specified result in a range of ports that exceeds the maximum port number of 65535, the ports up to 65535 are reserved and those greater than 65535 are ignored.

jobname

Specifies the MVS job name that can use the specified port or any unreserved port in the case of a PORT UNRSV statement. You can specify the *jobname* value as one of the following values:

- The 1 - 8 character name of the job that is required to use the port.
- A 1 - 8 character value including wildcard characters. The following wildcard characters are supported:
 - An asterisk (*) can be used in any position in the value to indicate zero or more unspecified characters.
 - A question mark (?) can be used in any position in the value to indicate a single unspecified character.

For example, the job name *searchee* matches a PORT statement whose job name value is **ar?he**. But the job name *searhee* does not match a PORT statement whose job name value is **ar?he**.

- An asterisk (*) wildcard character. Specify an asterisk as the *jobname* value to reserve a port without specifying a particular job name. You can use an asterisk if you do not know the exact job name or if you want to allow different applications to serially bind to the port.
- A 1 - 7 character prefix that is followed by an asterisk wildcard value. This specification enables all job names that match the prefix to access the port.

Restrictions:

- For UDP, only one job name can be associated with a port.
- To reserve a port that is to be monitored by the AUTOLOG function, the *jobname* value must exactly match the *jobname* value on the AUTOLOG statement; you cannot use a wildcard value.

Guideline: If a TCP port is to be shared by multiple users, use the PORT statement instead. The PORTRANGE statement does not support sharing of ports.

Determining the job name to be associated with a particular client or server application depends on the environment in which the application is run.

- Applications run from batch use the batch job name.
- Applications started from the MVS operator console use the started procedure name as the job name.
- Applications run from a TSO user ID use the TSO user ID as the job name.
- Applications run from the z/OS shell normally have a job name that is the logged on user ID plus a 1-character suffix.
- Authorized users can run applications from the z/OS shell and use the _BPX_JOBNAME environment variable to set the job name. In this case, the value specified for the environment variable is the job name.
- Use the name of the started JCL procedure for the UNIX System Services kernel address space to enable any application (except for applications using the Pascal API) to bind to the port. This name is typically OMVS unless a different name is explicitly specified in the STARTUP_PROC parameter in the BPXPRMxx parmlib member.
- To reserve the port and not allow any application access to it, use the name RESERVED.
- To reserve ports for the FTP server's use as passive data ports, use the name AUTHPORT and the protocol TCP. You must also code the PASSIVEDATAPORTS value in the FTP server's FTP.DATA data set.
- Use the name of the VTAM started task for the UDP ports that are to be used for Enterprise Extender (EE) network connections.

Restriction: The VTAM jobname can NOT include a wildcard character when it reserves EE UDP ports.

RESERVED

Indicates that all ports in the port range are not available for use by any user.

AUTHPORT

Indicates that all ports in the port range are not available for use by any user except FTP, and only when FTP is configured to use PASSIVEDATAPORTS. AUTHPORT is valid only with the TCP protocol.

NOAUTOLOG

Tells the TCP/IP address space *not* to restart the server if it was stopped previously. Otherwise, the default is to restart the server if it was stopped previously.

DELAYACKS | NODELAYACKS

NODELAYACKS

Specifies that an acknowledgment is returned immediately when a packet is received with the PUSH bit on in the TCP header. The NODELAYACKS parameter on the PORTRANGE statement, affects only connections that use this port. Specifying the NODELAYACKS parameter on the PORTRANGE statement overrides the specification of the DELAYACKS parameter on the TCP/IP stack TCPCONFIG profile statement, or on any of the following statements used to configure the route used by the TCP connection:

- The TCP/IP stack BEGINROUTES profile statement
- The Policy Agent RouteTable statement
- The OMPROUTE configuration statements

DELAYACKS

Delays transmission of acknowledgments when a packet is received with the PUSH bit on in the TCP header. The DELAYACKS parameter on the PORTRANGE statement affects only connections that use this port. This is the default, but the behavior can be overridden by specifying the NODELAYACKS parameter on the TCP/IP stack TCPCONFIG profile statement, or on any of the following statements used to configure the route used by the TCP connection:

- The TCP/IP stack BEGINROUTES profile statement
- The Policy Agent RouteTable statement
- The OMPROUTE configuration statements

SAF *resname*

SAF *resname* indicates that all ports in the range are reserved for users that have READ access to the RACF resource.

```
EZB.PORTACCESS.sysname.tcpname.resname
```

where

- EZB.PORTACCESS is constant
- *sysname* is the value of the MVS &SYSNAME. system symbol
- *tcpname* is the name of the procedure used to start the TCP stack
- *resname* is a 1-8 character value following the SAF keyword

Restriction: You can not specify a 1-character value of 0 (zero) for *resname*.

If the SAF keyword is specified and an application tries to bind to a port in the port range, and the user ID associated with the application is not permitted to the resource, the BIND socket call fails.

This is optional and valid for TCP or UDP protocols.

If the *jobname* value is specified as an asterisk (*), any user ID that is RACF-permitted to the resource specified by the *resname* value is allowed to bind to the port; APF or superuser authority is not required.

Guideline: If an application binds to an IP address that is also specified in a VIPARANGE statement subnet, then additional security verification might occur to determine whether the application can create the dynamic VIPA (DVIPA). For information about [defining a security profile for binding to DVIPAs in the VIPARANGE statement](#), see [z/OS Communications Server: IP Configuration Guide](#)

SMC | NOSMC

Configuration of these parameters overrides configuration of the AUTOSMC monitoring function for the servers that are associated with the reserved port. The AUTOSMC monitoring function is the default option for the GLOBALCONFIG SMCGLOBAL parameter. However, the default AUTOSMC monitoring is activated only when you enable or disable SMC support on the GLOBALCONFIG profile statement.

- To enable or disable Shared Memory Communications over Remote Direct Memory Access (SMC-R) support, specify the SMCR or NOSMCR parameters on the GLOBALCONFIG profile statement.
- To enable or disable Shared Memory Communications - Direct Memory Access (SMC-D) support, specify the SMCD or NOSMCD parameters on the GLOBALCONFIG profile statement.

For more information, see [Use the AUTOSMC monitoring function in z/OS Communications Server: IP Configuration Guide](#).

NOSMC

Indicates that Shared Memory Communications (SMC) is not permitted for TCP connections that use any port in this range. This setting overrides the SMCGLOBAL AUTOSMC parameter on the GLOBALCONFIG profile statement and ensures that inbound TCP connections to any port in this range do not use SMC. NOSMC is valid only for TCP ports.

SMC

Indicates that the stack attempts to use SMC for inbound TCP connections that use any port in this range. This parameter is required only when you use the SMCGLOBAL AUTOSMC parameter on the GLOBALCONFIG profile statement and you want to ensure that the stack attempts to use SMC for inbound TCP connections. SMC is valid only for TCP ports.

Steps for modifying

To change a parameter value, you must delete the existing PORTRANGE statement by using the DELETE PORTRANGE statement, then redefine the parameter with the new PORTRANGE statement.

Examples

This example shows a PORTRANGE statement used to reserve a large number of ports for a single test system.

```
PORTRANGE
  4000 200  TCP TESTSYS
```

The following example shows a PORTRANGE statement that reserves port 111 for both UDP and TCP for one user, ports 500 - 504 for two different users, one using UDP and one using TCP, and ports 700 - 703 for TCP users with job names that begin with the prefix ABCD*.

```
PORTRANGE
  111  1  UDP  PORTMAP
  111  1  TCP  PORTMAP
  500  5  UDP  USER1
  500  5  TCP  USER2
  700  4  TCP  ABCD*
```

Usage notes

- A range of ports specified in a VARY TCPIP,,OBEYFILE command data set are added to the list of ports already reserved.
- Any user can use a port that is not reserved by a PORT or PORTRANGE statement. If you have TCP/IP hosts in your network that reserve ports in the range 1 - 1023 for privileged applications, you should reserve them either with this statement, the PORT statement, or the RESTRICTLOWPORTS parameter on the TCPCONFIG or UDPCONFIG statements.

- If you are reserving ports for the INADDRANYPORT() parameter in the BPXPRMxx SYS1.PARMLIB member, you must specify the name of the started JCL procedure for the z/OS UNIX kernel address space to enable any application (except for applications using the Pascal API) to bind to the port. This name is typically OMVS unless a different name is explicitly specified in the STARTUP_PROC parameter in the BPXPRMxx parmlib member. See [z/OS MVS Initialization and Tuning Reference](#) for more details about the STARTUP_PROC parameter. You can use IBM Health Checker for z/OS enhancements to check whether the range of ports specified by the INADDRANYPORT and INADDRANYCOUNT parameter of the BPXPRMxx parmlib member is reserved for OMVS on the TCP/IP stack when operating in a CINET environment. For more details about IBM Health Checker for z/OS enhancements, see [IBM Health Checker for z/OS](#) in the [z/OS Communications Server: IP Diagnosis Guide](#)
- The NOSMC option is enforced during TCP bind() processing. To allow servers that bind to a port in this range that is configured with the NOSMC option to use SMC communications, you need to perform the following steps:
 1. Delete the existing port reservations by using the VARY TCPIP,,OBEYFILE command with a data set that contains a DELETE PORTRANGE statement.
 2. Create reservations for the port by using the VARY TCPIP,,OBEYFILE command with a data set that contains a PORTRANGE statement without the NOSMC parameter.
 3. Stop and restart the servers that use the ports.

Related topics

- [“DELETE statement” on page 32](#)

PRIMARYINTERFACE statement

Restriction: The PRIMARYINTERFACE statement applies to IPv4 only.

Use the PRIMARYINTERFACE statement to specify which interface is to be designated as default local host for use by the GETHOSTID() function.

The PRIMARYINTERFACE statement's IP address is not used as the source IP address for any out-going datagrams, unless that same address is configured as the SOURCEVIPA address.

If the PRIMARYINTERFACE statement is not specified, then the first address in the HOME list is designated as the default local host. If no HOME statements are defined in the profile, PRIMARYINTERFACE defaults to the first IPv4 INTERFACE statement listed in the profile.

Syntax

➤ PRIMARYinterface — *interface_name* ➤

Parameters

interface_name

The name of an interface that is to be the primary interface. This interface must have already been defined to TCP/IP. If you specify the name of a dynamic VIPA interface, the dynamic VIPA must have been defined in a VIPADYNAMIC block. You cannot specify a loopback interface name.

Steps for modifying

To modify parameters for the PRIMARYINTERFACE statement, you must respecify the statement with the new parameters.

Include the PRIMARYINTERFACE statement in a VARY TCPIP,,OBEYFILE command data set under the following conditions:

- Your primary interface is defined by the DEVICE, LINK, and HOME profile statements.
- The VARY TCPIP,,OBEYFILE command data set includes a HOME statement.
- You want to preserve your primary interface settings.

If you do not include the PRIMARYINTERFACE statement under these conditions, the primary interface is reset to the first entry in the new HOME list. If your primary interface is defined by an INTERFACE profile statement, including a HOME statement in a VARY TCPIP,,OBEYFILE command data set does not affect the primary interface settings.

Examples

This example shows a PRIMARYINTERFACE statement specifying a channel-to-channel device:

```
PRIMARYINTERFACE CTCD00
```

You can verify which HOME entry is primary by using the Netstat HOME/-h command:

```
Home address list:
Address      Link      Flg
9.67.116.125 CTCD00    P
127.0.0.1    LOOPBACK
```

Usage notes

- Because of the way dynamic VIPA links are added to the TCP/IP stack, you cannot specify a PRIMARYINTERFACE statement for a dynamic VIPA link in the same Profile data set as the VIPADYNAMIC block that defines the dynamic VIPA link. This is true for the initial Profile data set or a Profile data set specified on a VARY TCPIP,,OBEYFILE command. In order to specify a dynamic VIPA link on a PRIMARYINTERFACE statement, the dynamic VIPA link must have been defined to the stack in a previous Profile data set.
- The primary interface is flagged in the Netstat HOME/-h display.

SACONFIG statement

Use the SACONFIG statement to configure the SNMP TCP/IP subagent. If the SACONFIG statement is not specified, the subagent is started by TCP/IP initialization but SNMP SET support is disabled.

Syntax

Tip: Specify the parameters for this statement in any order.

Parameters

AGENT

A port number in the range 1 - 65 535 used in establishing communication with the SNMP agent. For the TCP/IP SNMP subagent to communicate with the z/OS Communications Server SNMP agent, the port number specified must match the port number specified on the -p parameter when the SNMP agent is started. The default value is 161 when processing the initial profile only. If SACONFIG is specified in a VARY TCPIP,,OBEYFILE command data set without the AGENT parameter, the value is unchanged.

COMMUNITY

A 1 - 32 character string used as the community name (or password) in establishing contact with the SNMP agent. It is not converted to uppercase by profile processing. It cannot contain any imbedded white space or control characters (such as blank, tab, end of line, or end of file) and cannot contain any imbedded semicolons (semicolons are treated as comment delimiters). For the TCP/IP SNMP subagent to communicate with the z/OS Communications Server SNMP agent, the community name specified on the COMMUNITY keyword must match one that is defined in the PW.SRC or SNMPD.CONF data set used by the SNMP agent or specified on the -c parameter when the SNMP agent is started.

Restriction: The community name is case sensitive.

For more information about how the community name is used to permit access to the SNMP agent, see [Step 1: Configure the SNMP agent \(OSNMPD\)](#), in *z/OS Communications Server: IP Configuration Guide*.

The default value is *public* when processing the initial profile only. If SACONFIG is specified in a VARY TCPIP,,OBEYFILE command data set without the COMMUNITY parameter, the value is unchanged.

DISABLED

If specified in PROFILE.TCPIP at initialization, indicates that the SNMP subagent should not be started. Specify this parameter if you do not require any of the SNMP MIB data supported by the TCP/IP subagent. By default, the SNMP subagent is started by TCP/IP initialization.

If specified in a VARY TCPIP,,OBEYFILE command data set, indicates that the currently active subagent task should be terminated.

SNMP MIB objects supported by the z/OS Communications Server SNMP agent and subagents other than the TCP/IP SNMP subagent are still available. For information about which MIB objects are supported by the SNMP agent and subagent, see the [z/OS Communications Server: IP User's Guide and Commands](#).

ENABLED

Indicates that the SNMP subagent should be started at the completion of the initial profile processing, or of VARY TCPIP,,OBEYFILE command processing.

OSADISABLED

Indicates that OSA Management support is not required at this TCP/IP instance. If this support was previously enabled, then specifying this parameter disables the support.

OSAENABLED

Indicates that OSA Management support is required at this TCP/IP instance. For optimal performance, specify OSAENABLED only at the TCP/IP instance from which Management support is needed. By default, OSA data retrieval is not enabled.

The SNMP subagent must be enabled, as it provides support for retrieval of SNMP management data about OSA devices and links. Therefore, do not specify the DISABLED parameter for this TCP/IP instance.

To retrieve the data, there must also be at least one TCP/IP instance active for which the OSASF parameter and its port number have been specified in the SACONFIG statement.

OSASF *osacf_port_number*

A value between 0 and 65535. There is no default. A value in the range 1 - 65535 indicates a port number and marks the corresponding TCP/IP instance as a candidate to communicate with OSA/SF to retrieve SNMP OSA management data. A value of 0 indicates that the corresponding TCP/IP instance is no longer a candidate to communicate with OSA/SF, in the event that the OSA/SF-to-TCP/IP connection is restarted.

Guideline: When multiple TCP/IP instances specify that OSA management data retrieval is wanted, it is suggested that all be configured with the same OSASF parameter. Only one TCP/IP instance connects directly to OSA/SF. Other instances connect to OSA/SF using this primary TCP/IP instance.

SACACHETIME *cache_time*

The number of seconds (in the range 0 - 3 600) that the TCP/IP subagent caches management data. If a request for management data is received and the amount of time specified by the *cache_time* value has expired, the TCP/IP subagent retrieves a new copy of the management data from the TCP/IP stack. A value of 0 indicates that the TCP/IP subagent should not cache any data, but always retrieve the current value of the data from the TCP/IP stack. The default value is 30 seconds when processing the initial profile only. The subagent's *cache_time* value can also be changed by an SNMP SET request.

SETSDISABLED

Indicates that the SNMP subagent should not process SNMP SET requests.

SETSENABLED

Indicates that the SNMP subagent should process SNMP set requests. For example, SETSENABLED allows a user who issued an SNMP set request to cancel connections and start and stop devices using the SNMP agent security instead of RACF security. By default, the processing of SNMP SET requests is disabled.

Steps for modifying

To modify parameters for the SACONFIG statement, you must respecify the statement with the new parameters.

- If you modify the community name or Agent port number, you must recycle the TCP/IP subagent or the SNMP Agent for the changes to take effect.
- If you modify the OSA/SF port number, you must recycle the TCP/IP subagent or the OSA/SF IOASNP application for the changes to take effect.

Examples

```
SACONFIG COMMUNITY USACCESS AGENT 528
SACONFIG DISABLED
SACONFIG SETSENABLED OSAENABLED OSASF 2026
```

Usage notes

When you specify more than one SACONFIG statement in the initial profile data set, or in a data set referenced by the VARY TCPIP,,OBEYFILE command, the default value ENABLED is set even if the DISABLED value was specified in a previous SACONFIG statement.

SMFCONFIG statement

Use the SMFCONFIG statement to provide SMF logging for Telnet, FTP, IPSec, TCP/IP API, TCP/IP stack, Shared Memory Communications over Remote Direct Memory Access (SMC-R) activity, and Shared Memory Communications - Direct Memory Access (SMC-D) activity.

Using SMFCONFIG to turn on SMF logging allows you to request that standard subtypes are assigned to the TCP/IP SMF records. The SMFPARMS statement provides a similar capability but requires the installation to select the subtype numbers to be used. Use the SMFCONFIG statement instead of SMFPARMS. See the information about [accounting for SMF records in z/OS Communications Server: IP Configuration Guide](#).

The SMFCONFIG profile statement controls only whether SMF records are written to the MVS SMF data sets. Some of the SMF 119 records are also available to applications that connect to the following network management interface (NMI) services:

- Real time TCP connection SMF data NMI (SYSTPCPN)
- Real time SMF data NMI (SYSTCPSM)
- Real time zERT Detail SMF NMI (SYSTCPER)
- Real time zERT Summary SMF NMI (SYSTCPES)

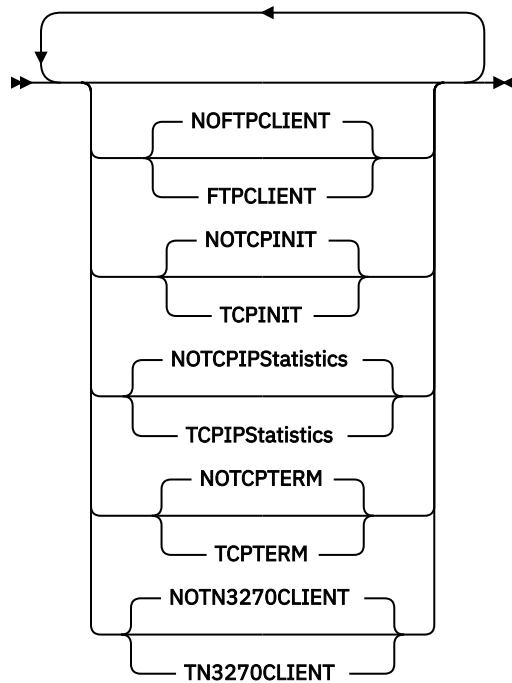

These functions are part of the real time TCP/IP network monitoring NMI. For more information about the real time TCP/IP network monitoring NMI functions, see [“NETMONITOR statement” on page 185](#). If you want your application to process only SMF 119 records by using the real time TCP/IP network monitoring NMI functions, you need to configure only the NETMONITOR profile statement. You do not need to request support for these records on the SMFCONFIG profile statement.

Syntax

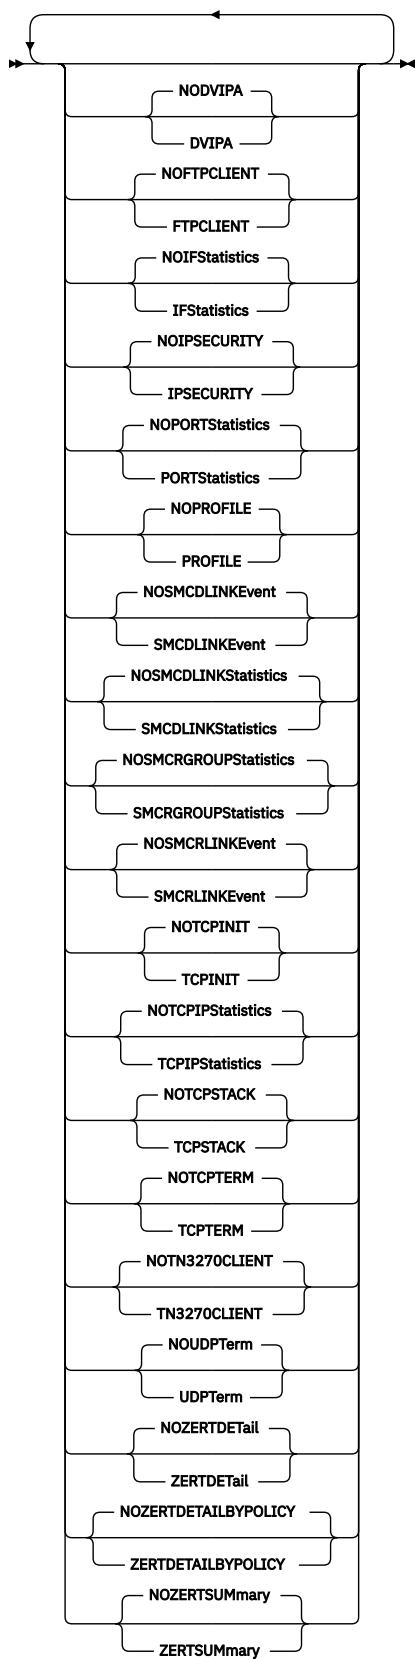

Tip: Specify the parameters for this statement in any order.

Type 118 Options

Type 119 Options

Parameters

DVIPA | NODVIPA

NODVIPA

Requests that SMF records of subtype 32, 33, 34, 35, 36, and 37 not be created when various sysplex events occur. This operand is valid if the current record type setting is TYPE119. This is the default value.

DVIPA

Requests that SMF records of subtype 32, 33, 34, 35, 36, and 37 be created when various sysplex events occur. This operand is valid if the current record type setting is TYPE119.

FTPCLIENT | NOFTPCLIENT

NOFTPCLIENT

Requests that SMF records of subtype 3 not be created when a user invokes the FTP client command. The record format affected (Type 118 or Type 119) by this operand is determined by the most recently specified setting of the TYPE118 or TYPE119 operand. This is the default value.

FTPCLIENT

Requests that SMF records of subtype 3 be created when a user invokes the FTP client command. The record format affected (Type 118 or Type 119) by this operand is determined by the most recently specified setting of the TYPE118 or TYPE119 operand.

IFSTATISTICS | NOIFSTATISTICS

NOIFSTATISTICS

Requests that SMF type 119 records of subtype 6, subtype 44, and subtype 45 not be created. This operand is valid if the current record type setting is TYPE119. This is the default value.

IFSTATISTICS

Requests that SMF type 119 records that are related to interface statistics are created. The following record subtypes are created:

- Subtype 6 records that contain statistics that are related to interface utilization
- Subtype 44 records that contain statistics that are related to *RoCE* interface utilization for SMC-R communications
- Subtype 45 records that contain statistics that are related to ISM interface utilization for SMC-D communications

Note that these records are created periodically based on the SMF interval in effect. This operand is valid if the current record type setting is TYPE119.

IPSECURITY | NOIPSECURITY

NOIPSECURITY

SMF type 119 records of subtypes 77, 78, 79, and 80 are not created. This operand is valid if the current record type setting is TYPE119. This is the default value.

IPSECURITY

Creates SMF type 119 records of subtypes 77 and 78 when a dynamic tunnel is added and removed. Creates SMF type 119 records of subtypes 79 and 80 when a manual tunnel is activated or deactivated. This operand is valid if the current record type setting is TYPE119.

PORTSTATISTICS | NOPORTSTATISTICS

NOPORTSTATISTICS

Requests that SMF type 119 records of subtype 7 not be created. This operand is valid if the current record type setting is TYPE119. This is the default value.

PORTSTATISTICS

Requests that SMF type 119 records of subtype 7 containing statistics related to reserved PORT utilization be created. Note that these records are created periodically based on the SMF interval in effect. This operand is valid if the current record type setting is TYPE119.

PROFILE| NOPROFILE

NOPROFILE

Requests that SMF type 119 records of subtype 4 not be created. This operand is valid if the current record type setting is TYPE119. This is the default value.

Results: If SMFCONFIG PROFILE is in effect, and then SMFCONFIG NOPROFILE is specified in a profile data set referenced by the VARY TCPIP,,OBEYFILE command, one final SMF type 119 record of subtype 4 is created to record the fact that this function has been turned off and no more SMF records of this subtype are created.

PROFILE

Requests that SMF type 119 records of subtype 4 be created. These records are SMF event records that provide TCP/IP stack profile information. They are created when the stack is first started and when profile changes occur as a result of VARY TCPIP,,OBEYFILE command processing. This operand is valid if the current record type setting is TYPE119.

SMCDLINKEVENT | NOSMCDLINKEVENT

NOSMCDLINKEVENT

Requests that SMF type 119 records of subtype 39 and 40 not be created. This operand is valid if the current record type setting is TYPE119. This is the default value.

SMCDLINKEVENT

Requests that SMF type 119 records of subtype 39 and 40 be created. The SMF records of subtype 39 are created when SMC-D links are started, and the SMF records of subtype 40 are created when SMC-D links are ended. This operand is valid if the current record type setting is TYPE119.

SMCDLINKSTATISTICS | NOSMCDLINKSTATISTICS

NOSMCDLINKSTATISTICS

Requests that SMF type 119 records of subtype 38 not be created. This operand is valid if the current record type setting is TYPE119. This is the default value.

SMCDLINKSTATISTICS

Requests that SMF type 119 records of subtype 38 containing statistics related to SMC-D links be created. These records are created periodically based on the SMF interval in effect. This operand is valid if the current record type setting is TYPE119.

SMCRGROUPSTATISTICS | NOSMCRGROUPSTATISTICS

NOSMCRGROUPSTATISTICS

Requests that SMF type 119 records of subtype 41 not be created. This operand is valid if the current record type setting is TYPE119. This is the default value.

SMCRGROUPSTATISTICS

Requests that SMF type 119 records of subtype 41 containing statistics related to SMC-R link groups be created. These records are created periodically based on the SMF interval in effect. This operand is valid if the current record type setting is TYPE119.

SMCRLINKEVENT | NOSMCRLINKEVENT

NOSMCRLINKEVENT

Requests that SMF type 119 records of subtype 42 and 43 not be created. This operand is valid if the current record type setting is TYPE119. This is the default value.

SMCRLINKEVENT

Requests that SMF type 119 records of subtype 42 and 43 be created. The SMF records of subtype 42 are created when SMC-R links are started, and the SMF records of subtype 43 are created when SMC-R links are ended. This operand is valid if the current record type setting is TYPE119.

TCPINIT | NOTCPINIT

NOTCPINIT

Requests that SMF records of subtype 1 not be created when TCP connections are established. The record format affected (Type 118 or Type 119) by this operand is determined by the most recent setting of the TYPE118 or TYPE119 operand. This is the default value.

TCPINIT

Requests that SMF records of subtype 1 be created when TCP connections are established. The record format collected (Type 118 or Type 119) is determined by the most recently specified TYPE118 or TYPE119 operand.

TCPIPSTATISTICS | NOTCPIPSTATISTICS

NOTCPIPSTATISTICS

Requests that SMF records of subtype 5 not be created. The record format affected (Type 118 or Type 119) by this operand is determined by the most recently specified setting of the TYPE118 or TYPE119 operand. This is the default value.

TCPIPSTATISTICS

Requests that SMF records of subtype 5 containing TCP/IP statistics be created. Note that these records are created periodically based on the SMF interval in effect. The record format collected (Type 118 or Type 119) is determined by the most recent setting of the TYPE118 or TYPE119 operand.

TCPSTACK | NOTCPSTACK

NOTCPSTACK

Requests that SMF type 119 records of subtype 8 not be created. This operand is valid if the current record type setting is TYPE119. This is the default value.

TCPSTACK

Requests that SMF type 119 records of subtype 8 be created when a TCP stack is activated and when it is terminated. This operand is valid if the current record type setting is TYPE119.

TCPTERM | NOTCPTERM

NOTCPTERM

Requests that SMF records of subtype 2 not be created when TCP connections are terminated. The record format affected (Type 118 or Type 119) by this operand is determined by the most recently specified setting of the TYPE118 or TYPE119 operand. This is the default value.

TCPTERM

Requests that SMF records of subtype 2 be created when TCP connections are terminated. The record format collected (Type 118 or Type 119) is determined by the most recently specified TYPE118 or TYPE119 operand.

TN3270CLIENT | NOTN3270CLIENT

NOTN3270CLIENT

Requests that SMF type 118 records of subtype 4, or type 119 records of subtype 22 or 23 not be created. The record format affected (Type 118 or Type 119) by this operand is determined by the most recently specified setting of the TYPE118 or TYPE119 operand. This is the default value.

TN3270CLIENT

Requests that SMF type 118 records of subtype 4, or type 119 records of subtype 22 and 23 be created when the TSO Telnet Client code initiates or terminates a connection (respectively for type 119). The record format collected (Type 118 or Type 119) is determined by the most recently specified TYPE118 or TYPE119 operand.

UDPTERM | NOUDPTERM

NOUDPTERM

Requests that SMF type 119 records of subtype 10 not be created. This operand is valid if the current record type setting is TYPE119. This is the default value.

UDPTERM

Requests that SMF type 119 records of subtype 10 be created when a UDP Socket is closed. This operand is valid if the current record type setting is TYPE119.

ZERTDETAIL|NOZERTDETAIL

Controls the creation of SMF type 119 records of subtype 11 for TCP and Enterprise Extender connections at connection initiation, connection termination, and when security characteristics for the connection change.

NOZERTDETAIL

Requests that SMF type 119 records of subtype 11 not be created when TCP and Enterprise Extender connections are initiated or terminated, or when the security characteristics of those connections change. This operand is valid if the current record type setting is TYPE119. This is the default value.

Note: Other subtype 11 records might still be created if ZERTDETAILBYPOLICY is enabled.

ZERTDETAIL

Requests that SMF type 119 records of subtype 11 be created for z/OS Encryption Readiness Technology (zERT) discovery function processing. The SMF records of subtype 11 are created when zERT discovery is enabled and TCP and Enterprise Extender connections are initiated or terminated, or when the security characteristics of those connections change. SMF records of subtype 11 are also created when zERT discovery is enabled, or disabled dynamically. This operand is valid if the current record type setting is TYPE119.

Rules:

- zERT connection detail SMF 119 records are only created when the z/OS Encryption Readiness Technology discovery function has been activated by specifying the ZERT parameter on the GLOBALCONFIG profile statement.
- Creation of the zERT connection detail SMF 119 records of subtype 11 by zERT policy-based enforcement, is not controlled by the ZERTDETAIL parameter. It is controlled by the ZERTDETAILBYPOLICY parameter.

ZERTDETAILBYPOLICY|NOZERTDETAILBYPOLICY

Controls the creation of SMF type 119 records of subtype 11 for TCP connections when the connections map to zERT policy-based enforcement (ZERT) rules with an audit action.

NOZERTDETAILBYPOLICY

Requests that SMF type 119 records of subtype 11 not be created by zERT policy-based enforcement, when TCP connections map to a ZERT rule with an audit action. This operand is valid if the current record type setting is TYPE119. This is the default value.

Note: Other subtype 11 records might still be created if ZERTDETAIL is enabled.

ZERTDETAILBYPOLICY

Requests that SMF type 119 records of subtype 11 be created by zERT policy-based enforcement. The SMF records of subtype 11 are created by zERT policy-based enforcement when zERT discovery is enabled and TCP connections map to a ZERT policy rule with an audit action. SMF records of subtype 11 are also created when zERT discovery is enabled or disabled dynamically. This operand is valid if the current record type setting is TYPE119.

For more information on the audit action, see [“ZERTAction statement” on page 1107](#).

Rules:

- zERT connection detail SMF 119 records are only created when the z/OS Encryption Readiness Technology discovery function has been activated by specifying the ZERT parameter on the GLOBALCONFIG profile statement.
- Creation of the zERT connection detail SMF 119 records of subtype 11, when TCP and Enterprise Extender connections are initiated or terminated, or when the security characteristics of those connections change, is not controlled by the ZERTDETAILBYPOLICY. It is controlled by the ZERTDETAIL parameter.

ZERTSUMMARY|NOZERTSUMMARY

NOZERTSUMMARY

Requests that SMF type 119 records of subtype 12 not be created. This operand is valid if the current record type setting is TYPE119. This is the default value.

ZERTSUMMARY

Requests that SMF type 119 records of subtype 12 be created for zERT aggregation function processing. These records are created periodically based on the SMF interval value in effect. SMF event records of subtype 12 are also created when zERT aggregation is enabled, or disabled dynamically. This operand is valid if the current record type setting is TYPE119.

Rule: zERT aggregation SMF 119 records are only created when the z/OS Encryption Readiness Technology aggregation function has been activated by specifying the ZERT AGGREGATION parameter on the GLOBALCONFIG profile statement.

Steps for modifying

To modify parameters for the SMFCONFIG statement, you must respecify the statement with the new parameters.

VARY TCPIP,,OBEYFILE command processing does not reset previous settings to the default.

Statement dependency

- Use of SMFCONFIG is preferable to SMFPARMS to standardize subtypes. If SMFPARMS is encountered after an SMFCONFIG statement, an error message is displayed and the SMFPARMS parameters are ignored. If SMFCONFIG is not coded, no SMF records are logged (assuming that SMFPARMS is not coded either).
- SMFPARMS is valid only for Type 118 records. Type 119 records have default subtype values that are not installation-configurable.

Examples

This example requests SMF records for TCP connection initialization, TCP connection termination, FTP client, Telnet client, and TCP/IP statistics:

```
SMFCONFIG TCPINIT TCPTERM FTPCLIENT TN3270CLIENT TCPIPSTATISTICS
```

The format type default is TYPE118. If you use SMFCONFIG to activate SMF recording, you do not need to make any changes to continue receiving the same recording. If you want to use the new records, specify TYPE119, followed by any of the SMF records that you want.

For example, if the following is specified:

```
SMFCONFIG FTPCLIENT TN3270CLIENT  
TYPE119 FTPCLIENT TN3270CLIENT
```

The recording is Type 118 FTP, TN3270 client records and Type 119 FTP, TN3270 client records.

Usage notes

Requirement: SMF must be active and properly configured to allow the recording of Type 118 or Type 119 records, depending on which types are being used by the configuration.

Tip: The TYPE118 keyword can be omitted when designating Type 118 options as long as they are specified before the Type 119 options.

SMFPARMS statement

Use the SMFPARMS statement to log the use of TCP by applications using SMF Type 118 log records. You can log Telnet and FTP client activity, and TCP API activity.

Syntax

Rule: Specify the parameters in the order shown here.

➤ SMFPARMS — *inittype* — *termtype* — *clienttype* ➤

Parameters

inittype

An integer in the range 0 - 255 specifying the subtype field in the API initialization records. The value 0 indicates that no API initialization is written.

termtype

An integer in the range 0 - 255 specifying the subtype field in the API termination records. The value 0 indicates no API termination records are written.

clienttype

An integer in the range 0 - 255 specifying the subtype field in the FTP or Telnet client. The value 0 indicates that no FTP or Telnet client records are written.

Steps for modifying

To modify parameters for the SMFPARMS statement, you must respecify the statement with the new parameters.

Statement dependency

SMFPARMS is valid only for Type 118 SMF records. Type 119 records have default subtype values that are not installation-configurable. As such, the only way to activate the recording of Type 119 records is by using SMFCONFIG.

Examples

- Either of the following statements would produce API initialization and termination records but no FTP or Telnet client records:

```
SMFPARMS 3 4 0
SMFPARMS 3 4
```

- The following statement would produce client records only:

```
SMFPARMS 0 0 5
```

- Because one of the parameters is missing, this statement would generate an error and not produce any records:

```
SMFPARMS 3
```

Usage notes

- The values for each subtype should be unique.
- If *inittype*, *termtype*, or *clienttype* have the value of 0, no attempt is made to write the respective record.

- The format of the log information differs for Telnet and FTP client activity, and TCP API activity.

SOMAXCONN statement

Use the SOMAXCONN statement to specify the maximum number of connection requests queued for any listening socket.

Syntax

Rule: Specify the parameters in the order shown here.

Parameters

maximum_queue_depth

The maximum number of pending connection requests queued for any listening socket. The minimum value is 1, the maximum value is 2147483647, and the default value is 1024.

This number is stored as a fullword integer, but most implementations of TCP/IP hardcode a value in the range 5 - 10.

This number is the maximum depth for any listening stream socket, but you can specify a shorter queue length when the listen performed for the socket.

Steps for modifying

To modify parameters for the SOMAXCONN statement, you must respecify the statement with the new parameters.

Examples

This example shows a SOMAXCONN statement specifying the default number of listening sockets.

SOMAXCONN	1024
-----------	------

Usage notes

- A SOMAXCONN constant with a value of 10 is defined in the SOCKET.H header file. If your C socket programs use this constant to determine the acceptable maximum listening backlog queue length, remember to change the header file to specify the value that you specified for TCP/IP for the maximum_queue_depth on the SOMAXCONN statement.

SRCIP statement

Use the SRCIP statement to do the following tasks:

- Designate source IP addresses for certain outbound TCP connections or server applications
- Designate whether to prefer a public or a temporary IPv6 address when the algorithm for default source address selection is used to select the source IP address for certain outbound TCP connections or for outbound UDP or RAW packets

Restriction: Only one SRCIP block should appear in a configuration data set. Any subsequent SRCIP blocks are ignored and an informational message is displayed. If a syntax error is encountered when this statement is processed, an error message is displayed and the entire SRCIP block is ignored (no entries are processed).

Guidelines:

- The SRCIP block does not require you to specify the SOURCEVIPA parameter on either the IPCONFIG statement or the IPCONFIG6 statement.
- SRCIP JOBNAME and DESTINATION entries can appear in any order. If an outbound connection matches more than one JOBNAME or DESTINATION entry, the following order of precedence is used:
 1. A match on the most specific JOBNAME entry with at least one, non-wildcard character (this excludes JOBNAME *)
 2. A match on the most specific DESTINATION entry
 3. A JOBNAME * entry

Designating source IP addresses for TCP connections

The SRCIP statement supports a combination of JOBNAME and DESTINATION entries to designate source IP addresses. Use the SRCIP JOBNAME statement to designate source IP addresses to be used for TCP applications identified by specified jobs. Use the SRCIP DESTINATION statement to designate source IP addresses to be used for outbound TCP connections destined for specified IP addresses, networks or subnets.

These source IP addresses override source IP address specification based on:

- The VIPA IP addresses in the HOME list or the SOURCEVIPAINTERFACE specification, if SOURCEVIPA was specified
- The TCPSTACKSOURCEVIPA IP address

See the information about [source IP selection](#) in *z/OS Communications Server: IP Configuration Guide* for the hierarchy of ways that the source IP address of an outbound connection is determined.

Guideline: Applications that bind to INADDR_ANY or to the unspecified IPv6 address (in6addr_any), and that match on a SRCIP JOBNAME or DESTINATION statement, do not have the designated IP address as its source address upon completion of the bind() call. The source address is not set to the designated address until completion of the subsequent connect() (client applications) or listen (server applications) call. This is important to note for applications that issue a getsockname() call after a bind() call.

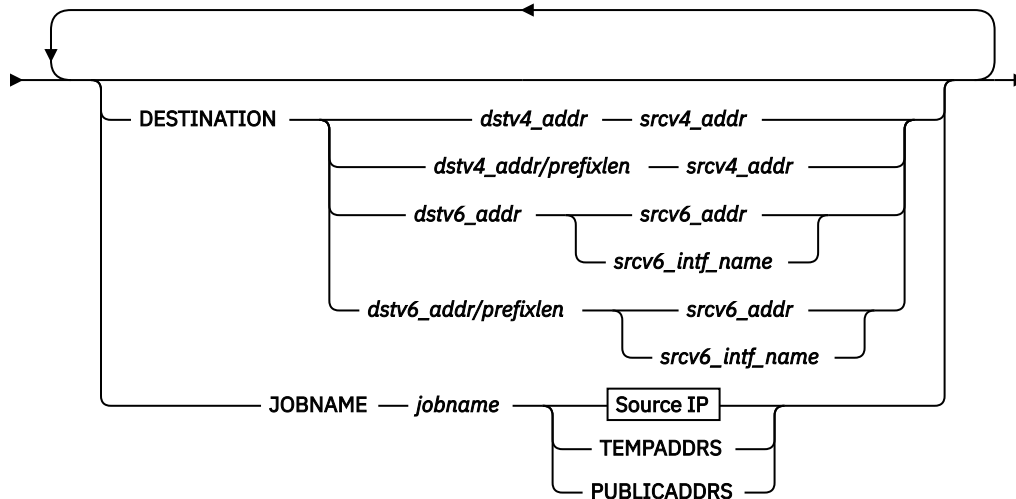

Designating whether to prefer a public IPv6 address or a temporary IPv6 address

Use the SRCIP JOBNAME statement to indicate whether to prefer a public IPv6 address or a temporary IPv6 address for an application that is identified by the specified job name. The preference for temporary or public IPv6 addresses is part of selecting a source address for an outbound packet using the algorithm for source address selection. For more information about default source IP address selection and about using IPv6 temporary addresses, see [z/OS Communications Server: IPv6 Network and Appl Design Guide](#).

Syntax

Rule: Specify the parameters for JOBNAME or DESTINATION entries in the order shown here.

➡ SRCIP ➡

➡ ENDSRCIP ➡

Source IP

Parameters

DESTINATION

Designates a source address or interface to be used for outbound TCP connections with destinations that match the specified destination address or network.

Restriction: The source address specified in a matching SRCIP DESTINATION entry cannot be a distributed DVIPA unless the GLOBALCONFIG EXPLICITBINDPORTRANGE profile parameter is configured and one of the following situations exist:

- The application issued a connect request without a prior explicit bind.
- The source port for the outbound TCP connection socket was explicitly bound to port 0, to a specified port that is less than 1024, or to a port that is reserved for this job by a PORT or PORTRANGE profile statement.

If GLOBALCONFIG EXPLICITBINDPORTRANGE is not configured or if the source port is explicitly bound to an ephemeral port (equal to or greater than 1024) that is not reserved for this job, the connection request fails.

Rule: If the source port is less than 1024 or is a port that is reserved for this job and the specified source is a distributed DVIPA, you must ensure that multiple outbound connections to the same destination IP address and port cannot occur concurrently with the same source IP address and port.

A match to a SRCIP DESTINATION entry cannot be identified until a connect request is issued and the destination is known. However, some applications establishing outbound TCP connections might issue an explicit bind socket API prior to issuing the connect request. The port that is assigned or specified during this early bind processing might not be available across the sysplex for the destination-specific source IP address that is determined later at connect request time. If the port is not available, then an ambiguous situation might occur in which multiple outbound connections to the same destination IP address and port have the same source IP address and port. For this

reason, the use of distributed DVIPAs on a SRCIP DESTINATION statement is not allowed without a GLOBALCONFIG EXPLICITBINDPORTRANGE statement configured on this stack.

Guideline: If you use distributed DVIPAs for the source IP address in a SRCIP DESTINATION entry, you should specify the SYSPLEXPORTS keyword on the VIPADISTRIBUTE statement for those distributed DVIPAs.

If duplicate destination values are specified in the SRCIP block, the first DESTINATION entry is used, any subsequent DESTINATION entry with a duplicate destination value is ignored, and a message is displayed.

If an outbound TCP connection's destination address matches more than one SRCIP destination address, the source address selected is determined by the most complete match. For example, suppose the following DESTINATION entries are specified in the SRCIP statement:

DESTINATION	9.67.0.0/16	10.1.1.1
DESTINATION	9.67.37.0/24	10.1.1.2

A destination address of 9.67.37.5 matches both DESTINATION entries, but 9.67.37.0/24 is the most specific match and 10.1.1.2 is selected as the source IP address for the outbound connection.

A DESTINATION designation is ignored if the job name for the connection matches any JOBNAME entry other than JOBNAME *.

dstv4_addr

IPv4 host address to be matched by the destination IP address of an outbound TCP connection request. This is the destination IP address with which a specified source address is associated

dstv4_addr/prefixlen

Subnet or network address to be matched by the destination IP address of an outbound TCP connection request. This is the destination IP subnet or network that a specified source address is associated with. The *dstv4_addr* value is a fully qualified IPv4 IP address and the *prefixlen* value is a decimal value in the range 1 - 32 that specifies how many of the leftmost contiguous bits of the address comprise the prefix.

dstv6_addr

IPv6 host address to be matched by the destination IP address of an outbound TCP connection request. This is the destination IP address that a specified source address or interface name is associated with. See [“Restrictions on IPv6 addresses configured in the TCP/IP profile” on page 83](#) for a list of restrictions that must be observed when specifying this parameter. If the stack is not IPv6-enabled and an IPv6 IP address is specified, the DESTINATION entry is ignored and a message is displayed.

dstv6_addr/prefixlen

Prefix address to be matched by the destination IP address of an outbound TCP connection request. This is the destination IP subnet or network that a specified source address or interface name is associated with. The *dstv6_addr* value is a fully qualified IPv6 IP address and the *prefixlen* value is a decimal value in the range 1 - 128 that specifies how many of the leftmost contiguous bits of the address comprise the prefix.

See [“Restrictions on IPv6 addresses configured in the TCP/IP profile” on page 83](#) for a list of restrictions that must be observed when specifying this parameter. If the stack is not IPv6-enabled and an IPv6 IP address is specified, the DESTINATION entry is ignored and a message is displayed.

srcv4_addr

IPv4 host address to be used as a source IP address if the associated destination address is matched. The specified IP address does not need to be defined prior to the processing of the SRCIP block but it must be defined before the first TCP connect request is issued for the associated destination, otherwise the connect request fails.

The *srcv4_addr* value is a static VIPA, a dynamic VIPA, or a real IPv4 address associated with a physical interface. If a dynamic VIPA is used, it can be defined by a VIPADEFINE statement or previously activated with bind() or the IOCTL SIOCSVIP value within a range of VIPAs.

Restrictions:

- An IPv4 source address cannot be specified for an IPv6 destination address.
- A distributed DVIPA cannot be specified for the source IP address in a DESTINATION entry unless the EXPLICITBINDPORTRANGE parameter on a GLOBALCONFIG statement is configured on this stack.

srcv6_addr

IPv6 host address to be used as a source IP address if the associated destination address is matched. The IPv6 IP address is in colon-hexadecimal format. A *prefix_length* cannot be specified. See “[Restrictions on IPv6 addresses configured in the TCP/IP profile](#)” on page 83 for a list of restrictions that must be observed when specifying this parameter. If the stack is not IPv6-enabled and an IPv6 IP address is specified, the DESTINATION entry is ignored and a message is displayed. The specified IP address does not need to be defined prior to the processing of the SRCIP block, but it must be defined before the first TCP connect request is issued for the associated destination; otherwise, the connect request fails.

The *srcv6_addr* value is a static VIPA, a dynamic VIPA, or a real IPv4 address associated with a physical interface. If a dynamic VIPA is used, it can be defined by a VIPADEFINE statement or previously activated with bind() or a IOCTL SIOCSVIP6 value within a VIPARANGE statement.

Restrictions:

- An IPv6 source address cannot be specified for an IPv4 destination address.
- A distributed DVIPA cannot be specified for the source IP address in a DESTINATION entry unless the EXPLICITBINDPORTRANGE parameter on a GLOBALCONFIG statement is configured on this stack.

srcv6_intf_name

The name of an IPv6 static VIPA, dynamic VIPA interface, or a physical interface to be used as a source interface if the associated destination address is matched. The maximum length is 16 characters. If a dynamic VIPA is used, it can be defined by a VIPADEFINE statement or previously activated with bind() or the IOCTL SIOCSVIP6 value within a VIPARANGE statement. If the stack is not IPv6-enabled, the DESTINATION entry is ignored and a message is displayed. The specified interface does not need to be defined prior to the processing of the SRCIP block, but it must be defined before the first TCP connect request is issued for the associated destination; otherwise, the connect request fails. If the interface has multiple IP addresses, then the source IP address for the outbound connection is selected from among these addresses according to the default source address selection algorithm. For more information, see the [default source address selection](#) information in [z/OS Communications Server: IPv6 Network and Appl Design Guide](#).

Restrictions:

- An IPv6 source interface cannot be specified for an IPv4 destination address.
- A distributed DVIPA cannot be specified for the source IP address in a DESTINATION entry unless the EXPLICITBINDPORTRANGE parameter on a GLOBALCONFIG statement has been configured on this stack.

JOBNAME

Use this keyword to do one of the following:

- Designate a source address or interface to be used for TCP applications with a job name that matches the specified job name.
 - The parameters CLIENT, SERVER, and BOTH designate the type of socket function call on which the source IP address should be used.
 - The application can be a server if it binds to the IPv4 INADDR_ANY address or to the IPv6 unspecified address (in6addr_any), and the keyword SERVER or BOTH is specified with the SRCIP JOBNAME statement specified with a value other than JOBNAME *.

See [Designate source IP addresses for TCP connections](#) for more information.

- Designate whether to prefer a temporary IPv6 address (TEMPADDRS) or a public IPv6 address (PUBLICADDRS) when the algorithm for default source address selection is used to select the source IP address for an application that has the specified job name.

See [Designate that a temporary IPv6 address is preferred over a public IPv6 address](#) and [Designate that a public IPv6 address is preferred over a temporary IPv6 address](#) for more information.

If a connection request matches both a job name value other than JOBNAME * and a SRCIP destination address, the matching JOBNAME entry is used; otherwise, the matching DESTINATION entry is used.

Designate source IP addresses for TCP connections

Use the following parameters to designate source IP addresses for TCP connections.

jobname

Specifies the MVS job name of the application with which the specified source IP address is associated. The *jobname* value can be up to 8 characters in length. A trailing asterisk (*) indicates a wildcard specification. If you specify an asterisk (*), then all qualifying TCP applications, except those whose destination matches a SRCIP destination address on connect requests, are associated with the specified source IP address or interface; any existing specifications indicated by TCPSTACKSOURCEVIPA parameter are overridden. If similar prefixes are specified (for example, PAY* and PAYR*), then the actual source IP address associated with a job name is determined by the most complete match between the prefix and the job name. For example, an application whose job name is PAYROLL would match the PAYR* JOBNAME entry, not the PAY* JOBNAME entry.

If you want to associate one job name with both an IPv4 and an IPv6 IP address, specify two JOBNAME entries in which the *jobname* value is the same but the IP addresses are of different IP address families. If duplicate job names are specified in the same SRCIP block, and the duplicate entries specify an IP address of the same IP type (for example, both entries specify IPv4 or both specify IPv6 IP address types) the first JOBNAME entry is in effect. Any duplicate JOBNAME entries are ignored and messages are displayed.

If duplicate job names are specified in the same SRCIP block, and one of the entries specifies an IPv6 address or interface and the other entry specifies TEMPADDRS, the first JOBNAME entry is in effect. Any duplicate JOBNAME entries that specify an IPv6 address or interface or TEMPADDRS are ignored and messages are displayed.

Restriction: Unless a GLOBALCONFIG EXPLICITBINDPORTRANGE statement is configured on this stack, you cannot use an IPv4 SRCIP JOBNAME entry that specifies a distributed DVIPA to select as the source IP address for a connection on an IPv6 socket to an IPv4-mapped destination. If you do use such an entry, the connection fails.

srcv4_addr

IPv4 host address to be used as a source IP address if it matches the associated job name. The specified IP address does not need to be defined prior to processing the SRCIP block but it must be defined before the TCP connect or listen request is issued by the associated job; otherwise, the connect or listen request fails.

The *ipv4_address* value can be a static VIPA, a dynamic VIPA, or a real IPv6 address associated with a physical interface. If you specify a dynamic VIPA, it can be defined by a VIPADefine statement or a VIPARANGE statement. If the dynamic VIPA is defined by a VIPARANGE statement, then it must have been activated with a bind() or IOCTL SIOCSVIPa value.

srcv6_addr

IPv6 host address to be used as a source IP address if it matches the associated job name. The IPv6 IP address is in colon-hexadecimal format. You cannot specify a prefix length. See [“Restrictions on IPv6 addresses configured in the TCP/IP profile” on page 83](#) for a list of restrictions that apply to this parameter. If the stack is not IPv6-enabled and an IPv6 IP address is specified, the JOBNAME entry is ignored and a message is displayed. The specified IP address does not need to be defined prior to processing the SRCIP block, but it must be defined before

the TCP connect or listen request is issued by the associated job; otherwise, the connect or listen request fails.

The *ipv6_address* value is a static VIPA, a dynamic VIPA, or a real IPv6 address that is associated with a physical interface. If you specify a dynamic VIPA, it can be defined by a VIPADEFINE statement or a VIPARANGE statement. If the dynamic VIPA is defined by a VIPARANGE statement, then it must have been activated with a bind() or IOCTL SIOCSVIPA value.

srcv6_intf_name

The name of an IPv6 static VIPA, dynamic VIPA interface, or a physical interface to be used as a source interface if it matches the associated job name. The maximum length is 16 characters. If a dynamic VIPA is specified, it can be defined by a VIPADEFINE statement or it could have been previously activated with bind() or IOCTL SIOCSVIPA6 value in a VIPARANGE statement. If the stack is not IPv6-enabled, the JOBNAME entry is ignored and a message is displayed. The specified interface does not need to be defined prior to processing the SRCIP block, but it must be defined before the TCP connect or listen request is issued by the associated job; otherwise, the connect or listen request fails. If the interface has multiple IP addresses, then the source IP address for the outbound connection is selected from among these addresses according to the default source address selection algorithm. For more information, see the [default source address selection](#) information in *z/OS Communications Server: IPv6 Network and Appl Design Guide*.

Guideline: When you are using a SRCIP JOBNAME statement for an IPv6 server application, code an IPv6 address (*srcv6_addr*) instead of an IPv6 interface (*srcv6_intf_name*); otherwise, the source address that is chosen for that IP interface might not be the best choice for the server application to be bound to. For more information, see the default source address selection algorithm information in *z/OS Communications Server: IPv6 Network and Appl Design Guide*.

CLIENT

Specifies that the source IP address should be used for client applications that are establishing outbound TCP connections that bind to the IPv4 INADDR_ANY address to IPv6 unspecified address (in6addr_any), or to the connect() call without having first completed a bind() call. The source IP address is determined on the subsequent connect() call. This value is the default.

SERVER

Specifies that the source IP address should be used to convert TCP server applications that bind to the IPv4 INADDR_ANY address or to the IPv6 unspecified address (in6addr_any), to bind to the specific source IP address. This means that only client applications that are using the designated IP address can connect to the server application. The source IP address is determined on the subsequent listen() call. When an application issues a getsockname() call after a bind() call to retrieve the source IP address, the processing is different from the processing that occurs when a TCP server application is converted to being bind specific using the BIND keyword on the PORT statements in the TCP/IP profile. When using the BIND keyword on the PORT statement, the designated IP address is set when the bind() call completes; some applications, such as Db2®, depend on this behavior.

BOTH

Specifies that the source IP address should be used for both client and server applications. For client applications, the source IP address is used for applications that invoke the bind() call with the IP INADDR_ANY address, the IPv6 unspecified address (in6addr_any), or the connect() call (for TCP outbound connections) without having first completed a bind() call. For server applications, the source IP address is used for applications that invoke the bind() call with the IP INADDR_ANY address or the IPv6 unspecified address (in6addr_any). The source IP address is determined on the connect() call for client applications and the listen() call for server applications.

Restriction: The options SERVER and BOTH are not valid with JOBNAME * specifications.

Designate that a temporary IPv6 address is preferred over a public IPv6 address

jobname

Specifies the MVS job name of the application for which temporary IPv6 addresses should be preferred over public IPv6 addresses. The *jobname* value can be up to 8 characters in length. A trailing asterisk (*) is a wildcard specification.

If duplicate job names are specified in the same SRCIP block and some of the duplicate entries specify an IPv6 address or interface and the other entries specify the value TEMPADDRS or PUBLICADDRS, the first JOBNAME entry is in effect. Any subsequent duplicate JOBNAME entries are ignored and messages are displayed.

TEMPADDRS

Specifies that this JOBNAME entry causes temporary IPv6 addresses to be preferred over public IPv6 addresses for the specified job when default source IP address selection is performed for the outbound packets.

Designate that a public IPv6 address is preferred over a temporary IPv6 address

jobname

Specifies the MVS job name of the application for which public IPv6 addresses should be preferred over temporary IPv6 addresses. The *jobname* value can be up to 8 characters in length. A trailing asterisk (*) is a wildcard specification.

If duplicate job names are specified in the same SRCIP block and some of the duplicate entries specify an IPv6 address or interface and the other entries specify the value TEMPADDRS or PUBLICADDRS, the first JOBNAME entry is in effect. Any subsequent duplicate JOBNAME entries are ignored and messages are displayed.

PUBLICADDRS

Specifies that this JOBNAME entry causes public IPv6 addresses to be preferred over temporary IPv6 addresses for the specified job when default source IP address selection is performed for the outbound packets. The application prefers public addresses by default.

Guideline: The environment in which the application is run determines the job name to be associated with a particular client or server application as follows:

- Applications submitted as batch jobs use the batch job name.
- The job name associated with applications started from the MVS operator console using the START command is determined as follows:
 - If the START command is issued with the name of a member in a cataloged procedure library (for example, S APP1), the job name is the member name (for example, APP1).
 - If the member name on the START command is qualified by a started task identifier (for example, S APP1.ABC), the job name is the started task identifier (for example, ABC). The started task identifier is not visible to all MVS components, but TCP/IP uses it to match a job name specified in the SRCIP block.
- The JOBNAME parameter can also be used on the START command to identify the job name (for example, S APP1,JOBNAME=XYZ).
- The JOBNAME parameter can also be included on the JOB card.
- Applications run from a TSO user ID use the TSO user ID as the job name.
- Applications run from the z/OS shell typically have a job name that is the user ID of the user that is logged on plus a 1-character suffix. Because this job name might not be predictable, you can use a job name ending in an asterisk (*) to ensure that these applications are governed by the SRCIP block. Because different applications might have the same job name, use care when you designate job names for applications running from the z/OS shell.
- Authorized users can run applications from the z/OS shell and use the _BPX_JOBNAME environment variable to set the job name. In this case, the value specified for the environment variable is the job name.
- z/OS UNIX applications started by INETD typically use the job name of the INETD server plus a 1-character suffix.

Steps for modifying

To modify parameters for the SRCIP block, consider the following:

- When a new SRCIP block is specified in a configuration data set on a VARY TCPIP,,OBEYFILE command, the new designations completely replace the existing designations.
- If you want to remove all the current designations, specify the SRCIP block without any entries, as indicated in the following example:

```
SRCIP ENDSRCIP
```

- If you want to change one of the designations, first create a SRCIP block with the existing set of designations. Update any JOBNAME or DESTINATION entry with the designation that needs to be changed. Then issue the VARY TCPIP,,OBEYFILE command to activate the change.
- Changing the source IP address in a JOBNAME or DESTINATION entry affects only new TCP connect requests for the job or destination address. It does not affect processing for any existing connections.
- Changing the TEMPADDRS or PUBLICADDRS setting in a JOBNAME entry affects only new TCP connect requests; it does not affect processing for existing connections.

Guidelines:

- While the SRCIP-ENDSRCIP statement allows the specification of real IP addresses that are associated with physical interfaces, use static or dynamic VIPA interfaces. Because static and dynamic VIPA interfaces are not associated with a specific physical interface, they provide higher availability attributes in cases where specific network interfaces fail or where connectivity is lost in specific parts of the network. In cases where a real IP address must be specified as a source IP address on the SRCIP-ENDSRCIP block statement, there are several considerations that should be carefully evaluated:
 - The IP address specified affects only the source IP address that is used for all packets associated with an outbound TCP connection for the specified jobs or destinations; it does not influence the physical network interface selected by TCP/IP for any outbound packets associated with the TCP connection. TCP/IP determines the outbound interface by consulting its routing table and determining the best route to the destination IP address for the connection. As a result, the source IP address that is selected might not be associated with the outbound physical interface selected by TCP/IP. The network routing topology must allow for any inbound packets for this connection to be routed back to this TCP/IP host regardless of the network interface that was used for any outbound traffic associated with this connection.
 - If the physical network interface associated with a specified IP address fails or is deactivated, any incoming packets destined to this IP address might not be able to reach this TCP/IP host. This could disrupt traffic for both existing TCP connections and new TCP connections that use this source IP address.
- For JOBNAME entries, if the same VIPA source IP address is used on more than one z/OS TCP/IP stack, then the job-specific source IP address should be a distributed DVIPA with the SYSPLEXPORTS parameter enabled.
- SRCIP DESTINATION statements will be created autonomically for VIPADISTribute dynamic VIPAs configured with the EXTTARG parameter (distributed DVIPA) if they are not manually configured. The autonomic SRCIP DESTINATION statements will use the IPCONFIG DYNAMICXCF IP address as the source IP address. This ensures local client applications will not use the distributed VIPA as the source IP address when connecting to a target with the distributed DVIPA.

For more information about the EXTTARG parameter, see [“VIPADYNAMIC - VIPADISTRIBUTE statement” on page 261](#).

Tips: Give careful consideration if:

- The designated source is a dynamic VIPA.

A dynamic VIPA that becomes inactive is no longer a valid designated source for SRCIP. A dynamic VIPA might become inactive if one of the following is true:

- It is no longer a target for sysplex distribution on this stack
- The application that causes its creation (in the case of an address created by a VIPARANGE statement) causes its deletion

- It has been deactivated by the VARY TCPIP,,SYSPLEX,DEACTIVATE command
- The DVIPA is in QUIESCING status
- The TCP/IP stack leaves the sysplex group
- The designated source is an interface name.

When an interface name is specified, it might be associated with multiple addresses. In this case, the address is chosen at connect time:

- If an interface has multiple addresses defined, the address chosen as the source IP address for the outbound connection is selected according to the default source address selection algorithm. For more information, see the [default source address selection information in z/OS Communications Server: IPv6 Network and Appl Design Guide](#).
- If the interface is a dynamic VIPA interface that is created by a VIPARANGE statement, then the actual address chosen as the source IP address for the outbound connection is not predictable or necessarily meaningful. Thus, you should specify an IPv6 address instead of an interface name if a VIPARANGE statement address is to be used.

- [“IPCONFIG6 statement” on page 156](#)

START statement

Use the START statement to start a device or interface that is currently stopped. This statement is usually specified at the end of *hlq.PROFILE.TCPIP*.

Requirements:

- VTAM must be active to START a device or interface with TCP/IP.
- Each device or interface to be started needs a separate START statement.

Tips:

- You can also use the VARY TCPIP,,START command to start a device or interface.
- The START statement can also be used in a VARY TCPIP,,OBEYFILE command data set to start the following:
 - A newly-defined device or interface
 - A device or interface stopped with the STOP statement
 - A device or interface that was never successfully started

Syntax

```
➔ START ———— device_name ———— ➔
           |
           | interface_name
           |
```

Parameters

device_name

The name of the device to start. This should be the same *device_name* specified on the DEVICE statement.

interface_name

The name of the interface to start. This should be the same *interface_name* specified on the INTERFACE statement or the name of a dynamically created interface, such as an IQDX interface.

Steps for modifying

Modification is not applicable to this statement.

Examples

This example shows START statements that start device LCS1.

```
START LCS1
```

Usage notes

- TCP/IP has a maximum of 255 non-VIPA started devices.
- There is no maximum number of static VIPA interfaces, but the maximum number of dynamic VIPA interfaces is 1024.
- The START statement is not valid for virtual devices or interfaces. When you use the DEVICE and LINK statements for IPv4, a virtual device is started automatically when a HOME entry is defined to it. When you use the IPv4 INTERFACE statement or when you use IPv6 , a virtual interface is started automatically when an INTERFACE statement is defined. The virtual device or interface never leaves the started (active) state.
- The START and STOP statements are processed after all other statements within the initial profile or VARY TCPIP,,OBEYFILE command data set.

Related topics

- [“STOP statement” on page 243](#)
- [z/OS Communications Server: IP System Administrator's Commands](#)

STOP statement

Use the STOP statement in a VARY TCPIP,,OBEYFILE command data set to stop a device or interface that is currently started.

Tip: You can also use the VARY TCPIP,,STOP command to stop a device or interface.

Syntax

```
➔ STOP ——— device_name ———➔  
      |  
      | interface_name |
```

Parameters

device_name

The name of the device to be stopped. This should be the same *device_name* specified on the DEVICE statement.

interface_name

The name of the interface to be stopped. This should be the same *interface_name* specified on the INTERFACE statement or the name of a dynamically created interface.

Steps for modifying

Modification is not applicable to this statement.

Examples

This example shows STOP statements that stop devices LCS1 and LCS2.

```
STOP LCS1  
STOP LCS2
```

Usage notes

- A virtual device or interface cannot be stopped.
- The START and STOP statements are processed after all other statements within the initial profile or VARY TCPIP,,OBEYFILE command data set.

Related topics

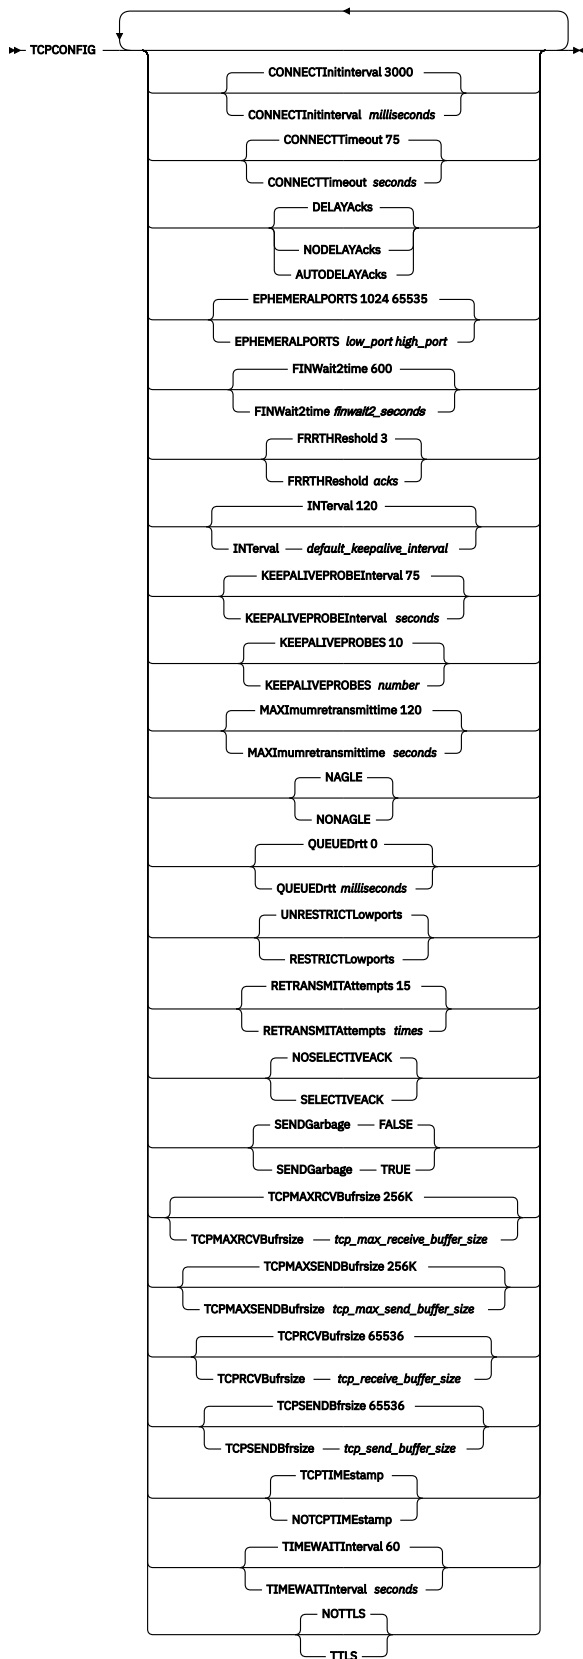

- [“START statement” on page 242](#)
- [z/OS Communications Server: IP System Administrator's Commands](#)

TCPCONFIG statement

Use the TCPCONFIG statement to update the TCP layer of TCP/IP.

Syntax

Tip: Specify the parameters for this statement in any order.

Parameters

CONNECTINITINTERVAL *milliseconds*

The initial retransmission interval in milliseconds. The range is 100 - 3000. The default value is 3000.

CONNECTTIMEOUT *seconds*

The number of seconds before the initial connection times out. This connection includes TCP connections that are established over SMC-R links. The range is 5 - 190. The default value is 75.

DELAYACKS | NODELAYACKS | AUTODELAYACKS**NODELAYACKS**

Specifies that an acknowledgement is returned immediately when data is received that has the PUSH bit set on in the TCP header. Specifying the NODELAYACKS parameter on the TCPCONFIG statement overrides the specification of the DELAYACKS parameter on the TCP/IP stack PORT or PORTRANGE profile statements for the port used by a TCP connection, or on any of the following statements used to configure the route used by a TCP connection:

- The TCP/IP stack BEGINROUTES profile statement
- The Policy Agent RouteTable statement
- The OMPROUTE configuration statements

DELAYACKS

Delays transmission of acknowledgments when a packet is received with the PUSH bit on in the TCP header. This is the default, but the behavior can be overridden by specifying the NODELAYACKS parameter on the TCP/IP stack PORT or PORTRANGE profile statements for the port used by a TCP connection, or on any of the following statements used to configure the route used by a TCP connection:

- The TCP/IP stack BEGINROUTES profile statement
- The Policy Agent RouteTable statement
- The OMPROUTE configuration statements

AUTODELAYACKS

Autonomically determines whether to delay or immediately transmit an acknowledgment when a packet is received with the PUSH bit on in the TCP header. This behavior is overridden when you specify the DELAYACKS or NODELAYACKS parameter on any of the following configuration statements for the port or the route that a TCP connection uses:

- The TCP/IP stack PORT profile statement
- The TCP/IP stack PORTRANGE profile statement
- The TCP/IP stack BEGINROUTES profile statement
- The Policy Agent RouteTable statement
- The OMPROUTE configuration statements

Note: If you use Policy-based routing (PBR) and centralized policy services, do not exploit the AUTODELAYACKS feature until all systems that use centralized policy services are upgraded to V2R2 or later systems. Otherwise, AUTODELAYACKS processing is in effect for all TCP traffic flowing over PBR routes, even when DELAYACKS or NODELAYACKS is specified in the policy.

EPHEMERALPORTS *low_port high_port*

Indicates the range of ephemeral ports that are to be assigned at bind time. The default ephemeral port range is 1024 - 65535.

low_port

The starting port for the range of ports. The *low_port* value is in the range 1024 - 65535.

high_port

The ending port for the range of ports. The *high_port* value is in the range 1024 – 65535, and must be greater than or equal to the *low_port* value.

Guidelines:

- The TCP/IP stack selects an ephemeral port from the range of ports that are defined on the EPHEMERALPORTS parameter only if an ephemeral port was not assigned by EXPLICITBINDPORTRANGE, SYSPLXPORTRANGE or PASSIVEDATAPORTS processing.

- The SYSPLEXPORTS processing uses only ports that are within the range of ports that the EPHEMERALPORTS parameter defines.
- For the ports within the EPHEMERALPORTS range, if they are reserved by using port reservation definitions or the EXPLICITBINDPORTRANGE parameter, they are excluded from the EPHEMERALPORTS port pool. Such exclusion effectively makes the pool smaller.

Restriction: Ports that are defined by BPXPARMS INADDRANYPORT and INADDRANYCOUNT must be restricted by the PORT or PORTRANGE statement to the job name OMVS. The stack does not assign these ports unless the user has the job name of OMVS.

FINWAIT2TIME *finwait2_seconds*

The number of seconds a TCP connection should remain in the FINWAIT2 state. The range is 1 - 3600. The default value is 600 seconds.

FRRTHRESHOLD *acks*

The threshold of duplicate ACKs for the fast retransmit and fast recovery function (FRR) to engage. The range is 1 - 2048. The default value is 3. Do not change this parameter from the default value unless a specific FRR-related problem occurs or you are under the direction of IBM service personnel.

INTERVAL *default_keepalive_interval*

The default TCP keepalive interval for applications that enable the SO_KEEPALIVE socket option and do not override the interval using the TCP_KEEPALIVE socket option. The range is 0 - 35791 minutes, and the default is 120. A value of 0 disables the keepalive function, so that sockets for which SO_KEEPALIVE is specified do not perform TCP keepalive. In this case, sockets specifying a specific interval using TCP_KEEPALIVE continue to send keepalive probes.

TCP keepalive probes end TCP connections after a period of inactivity. TCP keepalive is disabled by default for a connection, but can be enabled by issuing the SO_KEEPALIVE or TCP_KEEPALIVE socket options. The TCP_KEEPALIVE socket option enables the application to specify the keepalive probe interval, while the SO_KEEPALIVE socket option uses *default_keepalive_interval* as the interval.

After the interval has expired, TCP sends a single keepalive probe to the peer. If the TCP_KEEPALIVE socket option is not used to specify the probe interval, a total of ten probes are then sent at 75-second intervals if no response is received from the peer. If no response has been received 75 seconds after the last probe, the connection is reset. If TCP_KEEPALIVE is used to specify the keepalive probe interval, the number of probes and the interval between the probes might differ depending on the interval specified.

For more information about the TCP_KeepAlive socket option, see [TCP_KeepAlive socket option in z/OS Communications Server: IP Programmer's Guide and Reference](#).

KEEPALIVEPROBEINTERVAL *seconds*

The interval in seconds between keepalive probes. The range is 1 - 75. The default value is 75.

This parameter does not change the initial keepalive timeout interval. It controls only the time between the probes that are sent out after the initial keepalive interval has expired.

KEEPALIVEPROBES *number*

The number of keepalive probes before the connection is aborted. The range is 1 - 10. The default value is 10.

This parameter does not change the initial keepalive time out interval. It controls only the number of probes that are sent out after the initial keepalive interval has expired.

MAXIMUMRETRANSMITTIME *seconds*

The maximum retransmit interval in seconds. The range is 0 - 999,990. The default value is 120.

Rule: If none of the following parameters is specified, this MAXIMUMRETRANSMITTIME parameter is used and the MINIMUMRETRANSMITTIME parameters of the following statements are not used:

- MAXIMUMRETRANSMITTIME on the BEGINROUTES statement
- MAXIMUMRETRANSMITTIME on the ROUTETABLE statement
- Max_Xmit_Time on the OSPF_INTERFACE statement
- Max_Xmit_Time on the RIP_INTERFACE statement

The TCPCONFIG parameter value is used if no route parameter has been explicitly specified. If the TCPCONFIG parameter value of the maximum retransmit time is used, the MINIMUMRETRANSMITTIME value that is specified on the route parameter is not used, which means the minimum retransmit time is 0.

MAXIMUMRETRANSMITTIME of 0 indicates that the smallest retransmission interval must be used. When 0 is specified, TCP/IP uses a maximum retransmission interval of approximately 100 milliseconds. Specifying a very low maximum retransmission interval can result in additional system overhead for increased retransmission processing.

NAGLE | NONAGLE

NAGLE

Specifies that the Nagle algorithm is enabled. This is the default value.

NONAGLE

Specifies that the Nagle algorithm is disabled.

Rules:

- If the setsockopt() with TCP_NODELAY is specified for a connection, the Nagle algorithm is disabled for the connection.
- If NONAGLE is specified, the setsockopt() with TCP_NODELAY is ignored.

QUEUEDRTT *milliseconds*

The threshold at which the stack considers a connection eligible for outbound serialization. The range is 0 - 50 milliseconds. The default value is 0 millisecond. A value of 0 indicates that all TCP connections are eligible for outbound serialization. If a non-zero value is specified, the stack considers a connection eligible for outbound serialization only after the round trip time (RTT) for the connection equals or exceeds the specified value. Do not change this parameter from the default setting unless specific problems with outbound serialization occur or you are under the direction of IBM service personnel.

Result: In any of the following conditions, the stack activates outbound serialization for a connection to improve performance, regardless of the value that is specified for QUEUEDRTT:

- IPsec is enabled for a connection.
- The connection has been identified as operating in bulk-data way, for example, an FTP data connection. The connection has also been registered to the bulk-mode ancillary input queue (AIQ) of an OSA feature that is enabled for inbound workload queuing.

For more information about outbound serialization, see [Outbound serialization in z/OS Communications Server: IP Configuration Guide](#).

RESTRICTLOWPORTS | UNRESTRICTLOWPORTS

RESTRICTLOWPORTS

When set, ports 1- 1023 are reserved for users by the PORT and PORTRANGE statements. The RESTRICTLOWPORTS parameter is confirmed by the message:

```
EZZ0338I TCP PORTS 1 THRU 1023 ARE RESERVED
```

Restriction: When RESTRICTLOWPORTS is specified, an application cannot obtain a port in the 1-1023 range unless it is authorized. Applications can be authorized to low ports in the following ways:

- Using PORT or PORTRANGE with the appropriate job name or a wildcard job name such as * or OMVS. If the SAF keyword is used on PORT or PORTRANGE, additional access restrictions can be imposed by a security product, such as RACF.
- APF authorized applications can access unreserved low ports.
- OMVS superuser (UID(0)) applications can access unreserved low ports.

Applications with a dependency on being able to obtain an available port in the 1- 1023 range without having that port explicitly reserved for its use should be run as APF authorized or superuser. Use RESTRICTLOWPORTS to increase system security.

UNRESTRICTLOWPORTS

When set, ports 1 - 1023 are not reserved. This is the default value. The UNRESTRICTLOWPORTS parameter is confirmed by the message:

```
EZZ0338I TCP PORTS 1 THRU 1023 ARE NOT RESERVED
```

RETRANSMITATTEMPTS *times*

A segment will be retransmitted up to, but not including, the *times* value specified before the connection is aborted. For example, if *times* is set to 6 then the segment will be retransmitted 5 *times* and then aborted on the 6th retransmission timeout. The range is 0 - 15. The default value is 15.

SELECTIVEACK | NOSELECTIVEACK

SELECTIVEACK

Enables the exchange of selective acknowledgements with partners that support the selective acknowledgement (SACK) option as defined by RFC 2018. For information about this RFC, see [Appendix C, “Related protocol specifications,” on page 1349](#).

If TCP/IP initiates a TCP connection, then a selective acknowledgement permit option is sent. During a passive connect, if TCP/IP receives a TCP connection request with a selective acknowledgement permit option from a client and the SACK option is enabled, then TCP/IP sends a SYN-ACK with its own selective acknowledgement permit option. The SACK option must be enabled to help prevent unnecessary packets from being retransmitted when packet loss occurs in the network.

NOSELECTIVEACK

Disables the exchange of selective acknowledgements during connection setup and also during the entire connection. This is the default value.

SENDGARBAGE

Specifies whether the keepalive packets sent by TCP contain 1 byte of random data.

FALSE

Causes the packet to contain no data. This is the default value.

TRUE

Causes the packet to contain 1 byte of random data and an incorrect sequence number, assuring that the data is not accepted by the remote TCP.

TCPMAXRCVBUFSIZE *tcp_max_receive_buffer_size*

The TCP maximum receive buffer size is the maximum value an application can set as its receive buffer size using SETSOCKOPT(). The minimum acceptable value is the value coded on TCPRCVBUFSIZE, the maximum is 2 MB, and the default is 256 KB. If you do not have large bandwidth interfaces, you can use this parameter to limit the receive buffer size that an application can set.

Note: If Dynamic right sizing (DRS) is active for a connection, the TCPMAXRCVBUFSIZE value is ignored and a maximum value of 2 MB is used. For more information about DRS, see [TCP receive window in z/OS Communications Server: IP Configuration Guide](#).

IBM Health Checker for z/OS can be used to check whether the TCPMAXRCVBUFSIZE value is sufficient to provide optimal support to the z/OS Communications Server FTP server. By default, it checks that TCPMAXRCVBUFSIZE is at least 180 K. For more details about IBM [IBM Health Checker for z/OS](#), see [z/OS Communications Server: IP Diagnosis Guide](#).

TCPMAXSENDERBUFSIZE *tcp_max_send_buffer_size*

The maximum send buffer size, which is between the value that is specified on the TCPSENDERBUFSIZE parameter and 2 MB. The default value is 256 KB.

Note: If outbound right sizing (ORS) is active for a connection, the TCPMAXSENDBUFRSIZE value is ignored and a maximum value of 2 MB is used. For more information about ORS, see [TCP send window](#) in *z/OS Communications Server: IP Configuration Guide*.

TCPRCVBUFRSIZE *tcp_receive_buffer_size*

The TCP receive buffer size, which is between 256 bytes and the TCPMAXRCVBUFRSIZE value. The default value is 65536. This value is used as the default receive buffer size for those applications that do not explicitly set the buffer when they use SETSOCKOPT().

Increasing the receive buffer size does not allocate or consume any additional storage. The receive buffer size determines the amount of data that TCP/IP can buffer for the application to receive. When the TCP/IP stack receives the data, the data is stored in CSM data space or TCP/IP private storage. Each received segment has an associated data descriptor that resides in ECSA or TCP/IP private. No external mechanism controls which storage type is selected for the received data. For more information about the receiver buffer size and the TCP receive window, see [TCP receive window](#) in *z/OS Communications Server: IP Configuration Guide*.

TCPSENBFRSIZE *tcp_send_buffer_size*

The TCP send buffer size, which is between 256 bytes and the TCPMAXSENDBUFRSIZE value. The default value is 65536. This value is used as the default send buffer size for those applications that do not explicitly set the buffer size when they use SETSOCKOPT().

Increasing the send buffer size does not allocate or consume any additional storage. The send buffer size determines the amount of data that TCP/IP can buffer for the application to send. When the application sends the data, the TCP/IP stack stores the data in CSM data space. The sent data has one or more associated data descriptors that reside in ECSA. For more information about the send buffer size and the TCP send window, see [TCP send window](#) in *z/OS Communications Server: IP Configuration Guide*.

TCPTIMESTAMP | NOTCPTIMESTAMP

NOTCPTIMESTAMP

TCP Timestamp Option is disabled, and MVS does not participate in TCP timestamp negotiation during connection setup and also during the entire life of connection.

TCPTIMESTAMP

TCP Timestamp Option is enabled. If MVS initiates a TCP connection, then a TCP timestamp option is sent. During a passive connect, for example, if MVS receives a TCP connection request with TCP timestamp option from a client and this option is enabled, then MVS sends a SYN-ACK with its own TCP timestamp option. This option should be enabled to help prevent wrapping of sequence numbers or to prevent a connection from receiving a delayed segment that was originally intended for an earlier incarnation of the connection. The sequence numbers can wrap more quickly with higher bandwidth networks. This is the default value.

TIMEWAITINTERVAL *seconds*

The number of seconds that a connection remains in the TIMEWAIT state. The range is 0 - 120. The default value is 60.

TTLS | NOTTLS

NOTTLS

Indicates that the Application Transparent Transport Layer Security (AT-TLS) function is not activated for the TCP/IP stack. This is the default value.

TTLS

Indicates that the AT-TLS function is activated for the TCP/IP stack. The AT-TLS function provides invocation of System SSL in the TCP transport layer of the stack. When a TCPCONFIG TTLS value is specified, the AT-TLS function uses AT-TLS policy information that is configured by using Policy Agent to determine how application connections are processed. If the setting is modified by using the VARY TCPIP,,OBEYFILE command, only new connections are affected by the change.

Guideline: If AT-TLS is enabled, you must activate the SERVAUTH class, define the INITSTACK resource profile, and permit users to it.

For more information about [Application Transparent Transport Layer Security data protection](#), see [z/OS Communications Server: IP Configuration Guide](#).

Steps for modifying

To modify parameters for the TCPCONFIG statement, you must respecify the statement with the new parameters.

For all parameters except AUTODELAYACKS, the parameter changes do *not* affect existing connections. The changes affect only new connections.

Examples

This example shows a TCPCONFIG statement that reserves ports 1 - 1023 for users by the PORT and PORTRANGE statements:

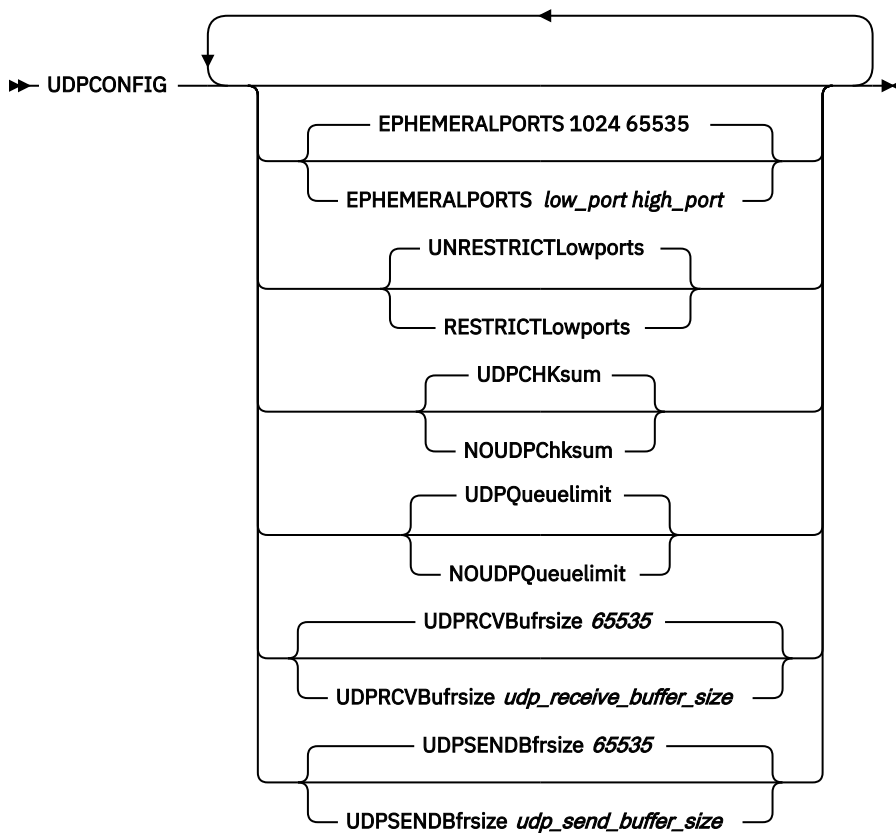

```
TCPCONFIG RESTRICTLOWPORTS
```

UDPCONFIG statement

Use the UDPCONFIG statement to update the UDP layer of TCP/IP.

Syntax

Tip: Specify the parameters for this statement in any order.

Parameters

EPHEMERALPORTS *low_port high_port*

Indicates the range of ephemeral ports that are to be assigned at bind time. The default ephemeral port range is 1024 - 65535.

low_port

The starting port for the range of ports. The *low_port* value is in the range 1024 - 65535.

high_port

The ending port for the range of ports. The *high_port* value is in the range 1024 – 65535, and must be greater than or equal to the *low_port* value.

Guideline: Any ports that are reserved using port reservation definitions that are within the EPHEMERALPORTS range are excluded from the EPHEMERALPORTS pool, effectively making the pool smaller.

Restriction: Ports that are defined by BPXPARMS INADDRANYPORT and INADDRANYCOUNT must be restricted by the PORT or PORTRANGE statement to the job name OMVS. These ports will not be assigned by the stack unless the user has the job name of OMVS.

RESTRICTLOWPORTS | UNRESTRICTLOWPORTS

RESTRICTLOWPORTS

When set, ports 1 - 1023 are reserved for users by the PORT and PORTRANGE statements. The RESTRICTLOWPORTS parameter is confirmed by the message:

```
EZZ0338I UDP PORTS 1 THRU 1023 ARE RESERVED
```

Applications can be authorized to low ports in the following ways:

- By way of PORT or PORTRANGE with the appropriate job name or a wildcard job name such as * or OMVS. If the SAF keyword is used on PORT or PORTRANGE, additional access restrictions can be imposed by a security product (for example, RACF).
- APF authorized applications can access unreserved low ports.
- OMVS superuser (UID(0)) applications can access unreserved low ports.

Applications that have a dependency on being able to obtain an available port in the 1- 1023 range without having that port explicitly reserved for its use should be run as APF authorized or superuser. Use RESTRICTLOWPORTS to increase system security.

UNRESTRICTLOWPORTS

Ports 1 - 1023 are not reserved. This is the default value. The UNRESTRICTLOWPORTS parameter is confirmed by the message:

```
EZZ0338I UDP PORTS 1 THRU 1023 ARE NOT RESERVED
```

UDPCHKSUM | NOUDPCHKSUM

NOUDPCHKSUM

Used to ensure UDP does not do check summing. This option is ignored for UDP datagrams flowing over an IPv6 network, as UDP Checksum is a required function on an IPv6 network. If an AF_INET6 socket is used to send datagrams over an IPv4 network, this option disables the UDP checksum function.

UDPCHKSUM

Used to ensure UDP does check summing. This is the default value.

UDPQUEUELIMIT | NOUDPQUEUELIMIT

NOUDPQUEUELIMIT

Used to specify that UDP should not have a queue limit. With NOUDPQUEUELIMIT specified, it is possible for inbound datagrams to arrive and be queued to a UDP application's socket faster than the application can receive the datagrams. If so, the amount of data queued could be substantial, resulting in a possible shortage of system storage. For this reason, set a limit using

UDPQUEUELIMIT or by using an IDS Traffic Regulation policy. The NOUDPQUEUELIMIT parameter is confirmed by the message:

```
EZZ0336I NO LIMIT ON INCOMING UDP DATAGRAM QUEUE SET
```

If intrusion detection services (IDS) Traffic Regulation (TR) policy is in effect for a UDP port then NOUDPQUEUELIMIT is overridden for that port.

UDPQUEUELIMIT

Used to set a queue limit for UDP. If set, then a maximum of 2000 incoming datagrams are queued on a UDP socket. This is the default value. The UDPQUEUELIMIT parameter is confirmed by the message:

```
EZZ0336I A LIMIT ON INCOMING UDP DATAGRAM QUEUE SET
```

If intrusion detection services (IDS) Traffic Regulation (TR) policy is in effect for a UDP port, the queue limit size is controlled by the policy for that port.

UDPRCVBUFRSIZE *udp_receive_buffer_size*

The UDP receive buffer size. Valid values are in the range 1 - 65535. The default is 65535.

UDPSENBFRSIZE *udp_send_buffer_size*

The UDP send buffer size. Valid values are in the range 1 - 65535. The default is 65535.

Steps for modifying

To modify parameters for the UDPCONFIG statement, you must respecify the statement with the new parameters.

Examples

This example shows a UDPCONFIG statement that uses check summing, sets no queue limit, and sets the send buffer size to 8192:

```
UDPCONFIG UDPCHK NOUDPQ UDPSENB 8192
```

VIPADYNAMIC statement summary

Use the VIPADYNAMIC statement to start a block of definitions related to dynamic VIPAs (DVIPAs) and the sysplex distributor; use an ENDVIPADYNAMIC statement to end the block of definitions. A VIPADYNAMIC block can contain the following statements:

- [“VIPADYNAMIC - VIPADEFINE statement” on page 254](#)
- [“VIPADYNAMIC - VIPABACKUP statement” on page 258](#)
- [“VIPADYNAMIC - VIPADELETE statement” on page 261](#)
- [“VIPADYNAMIC - VIPADISTRIBUTE statement” on page 261](#)
- [“VIPADYNAMIC - VIPARANGE statement” on page 276](#)
- [“VIPADYNAMIC - VIPAROUTE statement” on page 280](#)

Rules:

- Within a single profile there should be only one VIPADEFINE or VIPABACKUP statement for a particular DVIPA. If the DVIPA does appear in more than one statement, a VIPADELETE statement must be specified before the last instance to ensure that it is not rejected.
- A stack is limited to no more than 4096 total configured or target VIPAs at any one time. A configured dynamic VIPA is one that was created in any of the following ways, and might or might not be active:

- Using VIPADefine
- Using VIPABackup
- Using an IOCTL SIOCSVIPa or SIOCSVIPa6 DEFINE value when this stack had a covering VIPARange statement
- Using a BIND when this stack had a covering VIPARange statement
- A stack is also limited to no more than 1024 configured or target VIPAs at any one time that were created by using VIPADefine/VIPABackup, or as the target DVIPa for a VIPADISTRIBUTE from another stack.
- Syntax errors in a VIPADYNAMIC block end further processing of the VIPADYNAMIC block. VIPADYNAMIC statements are processed up to the syntax error, and any remaining statements are ignored.
- The TCP/IP stack does not maintain interface counters for dynamic VIPa interfaces.

Syntax

Examples

This example shows the use of the VIPADefine, VIPADISTRIBUTE, VIPABackup, and VIPAROUTE statements within a VIPADYNAMIC/ENDVIPADYNAMIC block.

```

VIPADYNAMIC
VIPADefine 255.255.255.192 201.2.10.11 201.2.10.12
VIPADISTRIBUTE DEFINE SYSPLXEXPORTS TIMEDAFF 30 201.2.10.11
PORT 21 DESTIP 201.3.10.10 201.3.10.11
VIPABackup 100 201.2.10.13
VIPADefine DVIPa1 2001:0DB8:1::1
VIPADISTRIBUTE DISTMETHOD ROUNDROBIN DVIPa1 PORT 21 DESTIP ALL
VIPABackup 150 DVIPa2 2001:0DB8:2::2
VIPAROUTE 201.3.10.10 199.3.10.1
ENDVIPADYNAMIC
  
```

- “IPCONFIG statement” on page 143.
- “IPCONFIG6 statement” on page 156.

VIPADYNAMIC - VIPADefine statement

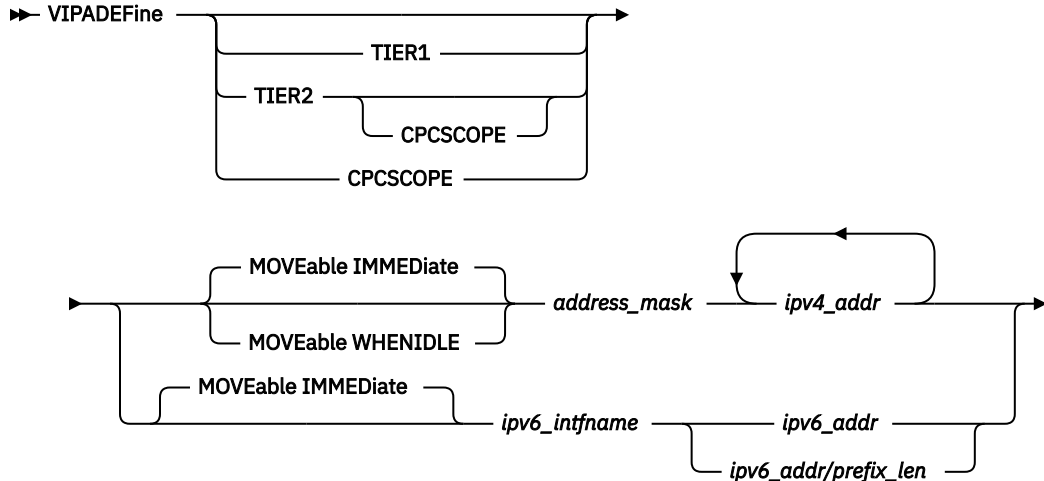

Designates one or more dynamic VIPAs (DVIPAs) that this stack should initially own and support. Other stacks can provide backup for these VIPAs if this stack fails.

Rule:

- Within a single profile there should be only one VIPADefine statement for a particular DVIPA. If the DVIPA does appear in more than one statement, you must specify a VIPADELETE statement before the last instance to ensure that the statement is not rejected.

Syntax

Rule: Specify the parameters in the order shown here.

Parameters

TIER1

Indicates that the dynamic VIPA whose address is specified as an IP address on this statement are used to distribute incoming requests to z/OS targets.

Restriction: You cannot configure this parameter on this statement if TIER2 is configured. A dynamic VIPA address cannot be used as both a TIER1 and TIER2 address.

TIER2

Indicates that the dynamic VIPA whose address is specified as an IP address on this statement are used to distribute incoming requests from Tier 1 targets to the group of server applications that is named.

Restriction: You cannot configure this parameter on this statement if TIER1 is configured. A dynamic VIPA address cannot be used as both a TIER1 and TIER2 address.

CPCSCOPE

Indicates that the dynamic VIPA whose address is specified as an IP address on this statement is specific to the central processor complex (CPC) on which it is defined. That is, it is not moved to, or taken over, by another TCP/IP stack that is in a different CPC.

Restrictions:

- A DVIPA defined with the CPCSCOPE parameter cannot be used in a VIPADISTRIBUTE DEFINE statement unless TIER2 is also configured .
- You cannot configure this parameter on this statement if TIER1 is configured.

MOVEABLE

This parameter is used to specify when a DVIPA that has been activated on this TCP/IP stack can be moved to another TCP/IP stack when the other TCP/IP stack requests ownership.

Rule: To preserve connections during dynamic VIPA takeover, you must specify the DYNAMICXCF parameter on the IPCONFIG statement for IPv4 DVIPA interfaces and on the IPCONFIG6 statement for IPv6 DVIPA interfaces.

IMMEDIATE

Specifies an immediate nondisruptive movement of a dynamic VIPA from one stack to another stack. This indicates that this dynamic VIPA can be moved to another stack as soon as the other stack requests ownership of the VIPA by executing a VIPADEFINE statement for the same dynamic VIPA. The new owning stack forwards packets for any existing connections to the original stack in order that the existing connections are not disturbed. All new connection requests are directed to the new owning stack. This is the default value.

The IMMEDIATE option is the only option supported for IPv6 addresses.

WHENIDLE

Indicates that this dynamic VIPA can be moved to another stack when there are no connections for this DVIPA on the current stack. While there are existing connections, any new connection requests continue to be directed to the current stack.

This option is not supported for IPv6.

address_mask

Specifies the subnet mask that determines how many of the bits of the IP address determine the subnet. All IP addresses in the same VIPADEFINE statement list must belong to the same subnet. That is, if the *address_mask* value is logically ANDed with all the IP addresses in the list, the resulting values must all be the same. The first IP address in the list determines the subnet.

The *address_mask* value is specified in standard dotted decimal format; the IP addresses in the subnet must be a single contiguous range of IP addresses. A subnet mask of 0.0.0.0 is not valid.

Rules: The *address_mask* value must meet the following normal mask definition rules:

- When converted to binary, the most significant bit must be 1.
- When converted to binary, all bits less significant than (to the right of) the first 0 encountered must also be 0.

Restriction: This parameter applies only to IPv4 addresses.

ipv4_addr

Specifies the specific DVIPA to be defined. More than one *ipv4_addr* value can be specified on a single VIPADEFINE statement. A mixture of IPv4 addresses and an IPv6 interface on the same VIPADEFINE statement is not permitted. A mixture of VIPADEFINE statements with all IPv4 addresses and VIPADEFINE statements with IPv6 addresses is permitted within the same VIPADYNAMIC/ENDVIPADYNAMIC block, and the VIPADEFINE statements can be intermixed in any order.

If a DVIPA in this VIPADEFINE statement list is already active on another stack as a dynamic VIPA that was activated by VIPADEFINE or VIPABACKUP statement, the result of this VIPADEFINE statement depends on the level of each stack and how the DVIPA was originally defined.

If the DVIPA was originally defined with MOVE IMMEDIATE, then the original owning stack immediately gives up ownership of the DVIPA and the DVIPA is activated on this stack. If there were any connections to the DVIPA on the original owning stack, the newly owning stack forwards packets to the original stack in order that the existing connections are not disturbed.

If two or more stacks in the sysplex have the same DVIPA in VIPADYNAMIC VIPADEFINE statements, with different address masks, the stack that gets the active DVIPA determines the address mask.

If a DVIPA in this VIPADEFINE statement list is already active on this stack or another stack either as an IP address in a HOME statement or as a dynamic VIPA activated by way of an IOCTL or a BIND implicit activation, the DVIPA in the VIPADEFINE statement list is rejected and an error message is issued.

ipv6_intfname

The name of the interface. The maximum length is 16 characters. This specified name and the address specified in *ipv6_addr* are verified to ensure that the DVIPA interface is uniquely (consistently) defined throughout the sysplex environment.

ipv6_addr

Specifies the specific DVIPA to be defined. Only one *ipv6_addr* value can be specified on a single VIPADEFINE statement. A mixture of IPv4 addresses and IPv6 interfaces on the same VIPADEFINE statements is not permitted. A mixture of VIPADEFINE statements with all IPv4 addresses and VIPADEFINE statements with an IPv6 address is permitted within the same VIPADYNAMIC/ENDVIPADYNAMIC block, and the VIPADEFINE statements can be intermixed in any order.

If the DVIPA specified by the *ipv6_addr* value is already active on another stack as a dynamic VIPA that was activated by the VIPADEFINE or VIPABACKUP statement on the same interface name, the DVIPA is activated on this stack and changed to backup status on the other stack.

Requirement: All stacks (distributing stack, backup stack, target stack) which participate in distribution for a distributed DVIPA with IPv6 address must be at least z/OS V1R6.

If the specified *ipv6_addr* is already active on this stack or another stack either as an IP address on an INTERFACE statement or as a dynamic VIPA activated by way of an IOCTL or a BIND implicit activation, the VIPADEFINE statement is rejected and an error message is issued.

See “Restrictions on IPv6 addresses configured in the TCP/IP profile” on page 83 for a description of the *ipaddr_spec* parameter and a list of restrictions that must be observed when specifying this parameter.

/prefix_len

Specifies the prefix length to be used when calculating a prefix for CPCSCOPE processing. The number of bits in the *ipv6_addr* value defines the prefix. Valid values are in the range 1 - 128.

When you specify the prefix length for a CPCSCOPE DVIPA, ensure that the prefix is the same subnet that is used for the tier 1 targets that are in this CPC.

Restriction: This parameter applies to IPv6 only.

Steps for modifying

- To remove one or more of the IPv4 addresses, use:

```
VIPADELETE  ipv4_addr  [ipv4_addr ...]
```

- To remove an IPv6 DVIPA interface, use:

```
VIPADELETE  ipv6_intfname
```

If the IPv4 DVIPA address or IPv6 DVIPA interface is being distributed, you must use one or more VIPADISTRIBUTE DELETE statements to end distribution before you can use the VIPADELETE statement to delete the DVIPA. The VIPADISTRIBUTE DELETE and VIPADELETE statements can appear in the same VARY TCPIP,,OBEYFILE command data set.

- To change the mask for one or more of the IPv4 addresses, you must first delete the IP addresses and then redefine them with the new mask:

```
VIPADELETE  ipv4_addr  [ipv4_addr ...]  
VIPADEFINE  new_mask  ipv4_addr  [ipv4_addr ...]
```

If the IP address is active, the VIPADELETE statement breaks any existing connections and causes the dynamic VIPA to be activated elsewhere in the sysplex if there is another stack prepared to activate it.

- To change a VIPADEFINE from TIER1 to TIER2, from TIER2 to TIER1, from non-TIER to TIER, or from TIER to non-TIER, you must first specify a VIPADELETE *ipaddr* value.

Examples

```
VIPADEFINE  255.255.255.192 9.67.240.02  
VIPADEFINE  TIER2 CPCSCOPE V6DVIPA1 2000::9:67:240:2/96
```

VIPADYNAMIC - VIPABACKUP statement

Designates one or more dynamic VIPAs (DVIPAs) for which this stack provides automatic backup if the owning stack fails. Another stack is expected, but not required, to have this same DVIPA defined with a VIPADYNAMIC VIPADEFINE statement.

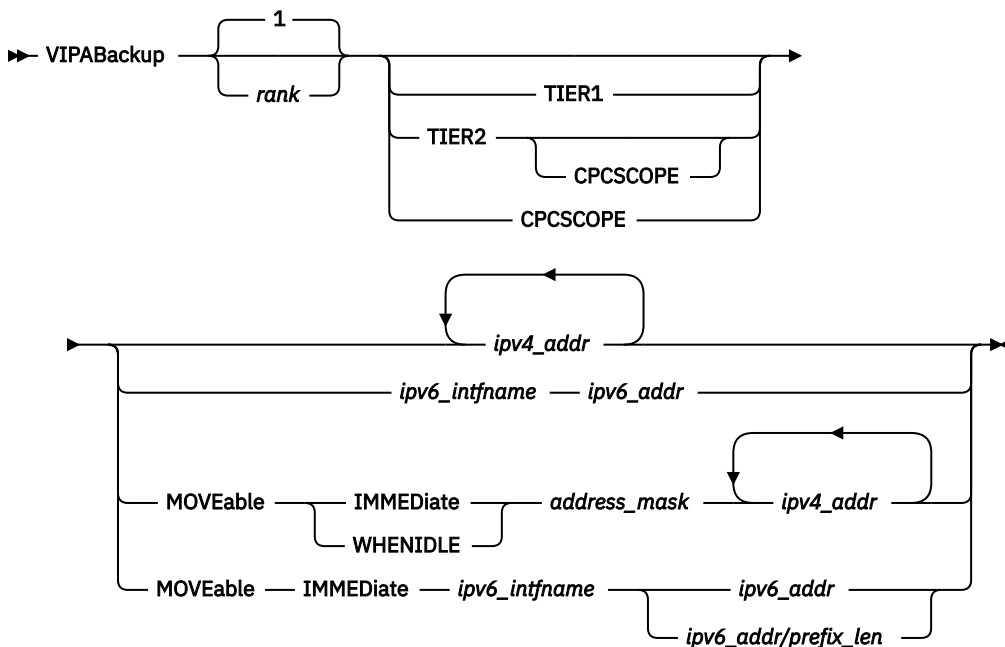

Rule:

- Within a single profile there should be only one VIPABACKUP statement for a particular DVIPA. If the DVIPA does appear in more than one statement, you must specify a VIPADELETE statement before the last instance to ensure that it is not rejected.

Syntax

Rule:

- Specify the parameters in the order shown here.

Parameters

rank

Specifies the intended order of the VIPAs in this VIPABACKUP statement list in their respective backup chains, relative to other stacks in those backup chains. Larger numerical rank values move the respective stacks closer to the beginning of the backup chain.

rank can be set to any integer from 1 (end of the backup chain) through 254 (start of the backup chain). Values 0 and 255 are reserved for use by the stacks themselves to temporarily force stack entries to the start or the end of the backup chain until an expected transition takes place.

The default is a rank of 1.

TIER1

Indicates that the dynamic VIPA whose address is specified as an IP address on this statement are used to distribute incoming requests to z/OS targets.

Restriction: You cannot configure this parameter on this statement if CPCSCOPE is configured.

TIER2

Indicates that the dynamic VIPA whose address is specified as an IP address on this statement are used to distribute incoming requests from Tier 1 targets to the group of server applications.

Rule: If CPCSCOPE is also configured on this statement, then the Tier 2 group of server applications is limited to TCP/IP stacks on this CPC.

CPCSCOPE

Indicates that the dynamic VIPA whose address is specified as an IP address on this statement is specific to the central processor complex (CPC) on which it is defined. The VIPA is not moved to or taken over by another TCP/IP stack that is in a different CPC. A DVIPA defined with this characteristic can be used as the default route for incoming requests from Tier 1 targets on this CPC.

Restrictions:

- A DVIPA defined with the CPCSCOPE parameter cannot be used in a VIPADISTRIBUTE DEFINE statement unless TIER2 is also configured.
- You cannot configure this parameter on this statement if TIER1 is configured.

MOVEABLE

This parameter is used to specify when a DVIPA that has been activated on this TCP/IP stack can be moved to another TCP/IP stack when the other TCP/IP stack requests ownership.

It can also be used to specify that the dynamic VIPA should be activated on this TCP/IP stack if it is not already active in the sysplex. If the DVIPA is already active in the sysplex when the VIPABACKUP statement is processed, this parameter is ignored. If you specify this parameter, you must also specify one of the following sets of dynamic VIPA information:

- The IPv4 address mask and address
- The IPv6 interface name and address

For more information about configuring VIPAs for activation with VIPABACKUP, see [z/OS Communications Server: IP Configuration Guide](#).

IMMEDIATE

Specifies that the DVIPA can be activated immediately on another TCP/IP stack. The TCP connections to this TCP/IP stack are preserved. If the DVIPA has been activated on this TCP/IP, and the TCP/IP where the DVIPA is defined by a VIPADEFINE statement is subsequently activated, the DVIPA is activated immediately on that TCP/IP. And the TCP connections to this TCP/IP are preserved.

WHENIDLE

Specifies that the DVIPA remains active on this TCP/IP stack until there are no more connections to the DVIPA on this stack. If the DVIPA is activated on this TCP/IP, and the TCP/IP where the DVIPA is defined by a VIPADEFINE statement is subsequently activated, the DVIPA remains active on this TCP/IP until there are no more connections to the DVIPA on this TCP/IP.

This option is not supported for IPv6.

Guideline: Support for the WHENIDLE parameter is limited. It is recommended to use the IMMEDIATE parameter instead of the WHENIDLE parameter

address_mask

Specifies the subnet mask or prefix to be used when building the BSDROUTINGPARMS entry for this DVIPA when it is activated. This parameter can be specified on a VIPABACKUP statement only when MOVEABLE is also specified, and this parameter is required when MOVEABLE is specified on a VIPABACKUP statement. It is specified in standard dotted decimal notation. A subnet mask of 0.0.0.0 is not valid.

This parameter is used only for activating the DVIPA when it is not already active in the sysplex. If the DVIPA is active when the VIPABACKUP statement is processed, this parameter is ignored.

Restriction: This parameter applies to IPv4 only.

ipv4_addr

Specifies the specific DVIPA to be backed up. More than one IPv4 address can be specified on a single VIPABACKUP statement. A mixture of IPv4 addresses and an IPv6 interface on the same VIPABACKUP statement is not permitted. A mixture of a VIPABACKUP statement with all IPv4

addresses, and a VIPABACKUP statement with an IPv6 interface, is permitted within the same VIPADYNAMIC/ENDVIPADYNAMIC block, and the VIPABACKUP statements can be intermixed in any order.

All *ipv4_addr* values specified on a single VIPABACKUP statement have the same rank. Use multiple VIPABACKUP statements to define different ranks for different *ipv4_addr* values.

The default LOOPBACK address (127.0.0.1) cannot be specified as the *ipv4_addr*.

ipv6_addr

Specifies the specific DVIPA to be backed up. Only one IPv6 address can be specified on a single VIPABACKUP statement. A mixture of VIPABACKUP statements with all IPv4 addresses, and VIPABACKUP statements with the IPv6 address, is permitted within the same VIPADYNAMIC/ENDVIPADYNAMIC block, and the VIPABACKUP statements can be intermixed in any order.

See “Restrictions on IPv6 addresses configured in the TCP/IP profile” on page 83 for a description of the *ipaddr_spec* parameter and a list of restrictions that must be observed when specifying this parameter.

/prefix_len

Specifies the prefix length to be used when calculating a prefix for CPCSCOPE processing. The number of bits in the *ipv6_addr* value defines the prefix. The range is 1 - 128.

When specifying the prefix length for a CPCSCOPE DVIPA, ensure that the prefix is the same subnet used for the tier 1 targets that are in this CPC.

Restriction: This parameter applies to IPv6 only.

ipv6_intfname

The name of the IPv6 interface to be backed up. The maximum length is 16 characters. Only one *ipv6_intfname* can be specified on a single VIPABACKUP statement. This specified name and the address specified in *ipv6_addr* are verified to ensure that the DVIPA interface is uniquely (consistently) defined throughout the sysplex environment.

Steps for modifying

- To remove an IPv4 address or IPv6 interface as a dynamic VIPA backup, use one of the following:
 - For an IPv4 address: `VIPADELETE ipv4_addr`
 - For an IPv6 interface: `VIPADELETE ipv6_intfname`
 - To change the rank (if the IP address is not currently active on this stack):

```
VIPABACKUP new_rank ipv4_addr
```

However, if the IP address is currently active, you must first delete it and then configure it with the new rank by using one of the following:

- ```
VIPADELETE ipv4_addr
```

```
VIPABACKUP new_rank ipv4_addr
```
- ```
VIPABACKUP new_rank ipv6_intfname ipv6_addr
```

or if the IP address is currently active, the VIPADELETE statement breaks any existing connections and causes the dynamic VIPA to activate elsewhere in the sysplex if there is another stack prepared to activate it.

- To remove an IPv6 interface and its address as a dynamic VIPA backup, use a VIPADELETE statement. *ipv6_intfname*.
- To modify the VIPABACKUP or VIPADELETE *ipv6_intfname* statement to remove an IP address as a dynamic VIPA backup, code the following:

```
VIPADELETE ipaddr
```

- To change a VIPABACKUP from TIER1 to TIER2, from TIER2 to TIER1, from non-TIER to TIER, or from TIER to non-TIER, you must first issue a VIPADELETE *ipaddr*.

Examples

```
VIPABACKUP V6DVIPA1 2000::9:67:240:2
VIPABACKUP 200 TIER2 CPCSCOPE MOVEABLE IMMEDIATE 255.255.255.192 9.67.240.02
```

VIPADYNAMIC - VIPADELETE statement

The VIPADELETE statement allows you to remove a dynamic VIPA interface from the VIPADEFINE or VIPABACKUP statement in which it occurs. It results in the interface and its dynamic VIPA being deleted.

Syntax

Parameters

ipv6_intfname

The name of the IPv6 interface as previously defined by a VIPADEFINE or VIPABACKUP statement. The maximum length is 16 characters. Only one interface name can be specified on a VIPADELETE statement.

ipv4_addr

Specifies the IPv4 IP address of the specific DVIPA to be deleted from the stack. More than one *ipv4_addr* value can be specified on a single VIPADELETE statement.

Examples

```
VIPADELETE 201.2.10.11
VIPADELETE DVIPA1
```

VIPADYNAMIC - VIPADISTRIBUTE statement

Enables (VIPADISTRIBUTE DEFINE) or disables (VIPADISTRIBUTE DELETE) the sysplex distributor function for a dynamic VIPA (defined on the same stack by a VIPADEFINE or VIPABACKUP statement) for which new connection requests can be distributed to other stacks in the sysplex. If you want to distribute FTP traffic, specify port 21 (or another designation according to which ports you are using for FTP) on the PORT parameter.

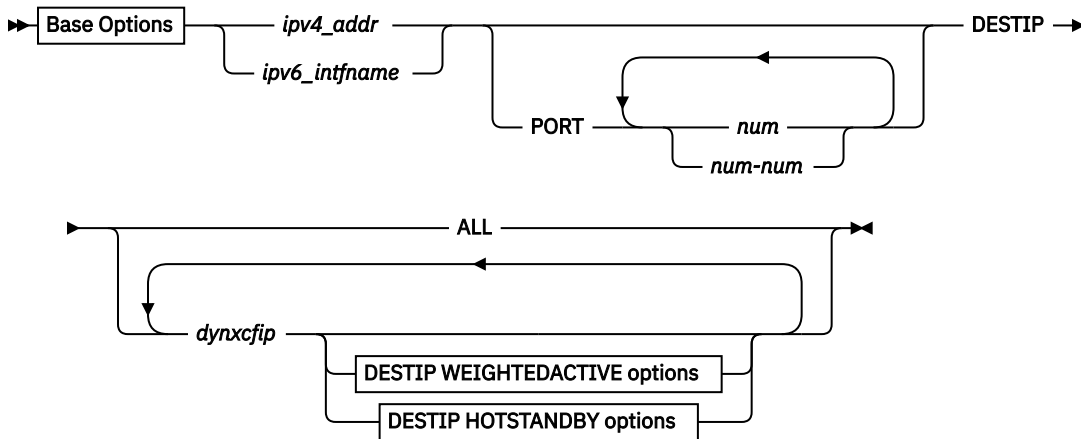

Tip: A target (or destination) DVIPA is one that was created on this stack as a result of a VIPADISTRIBUTE statement for an active VIPA on another stack. These addresses are identified by Flag I (internal only) in the Netstat HOME/-h command output.

Syntax

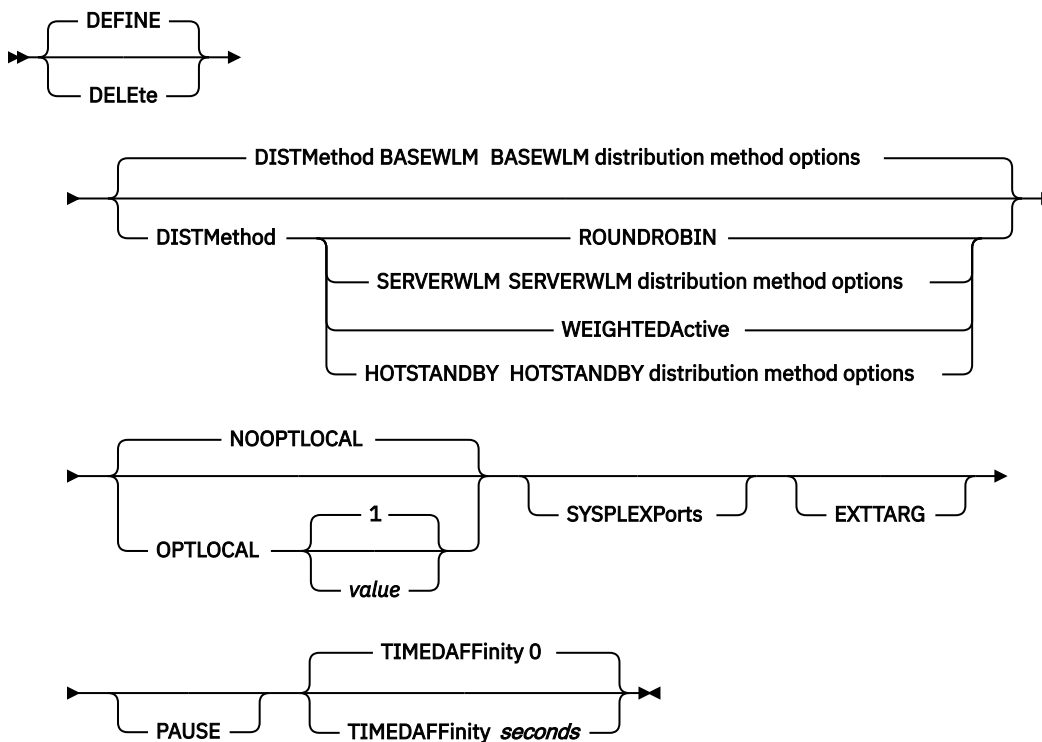

Rule: Specify the parameters in the order shown here, except for the optional parameters preceding the IPv4 address or IPv6 interface name, which can be specified in any order.

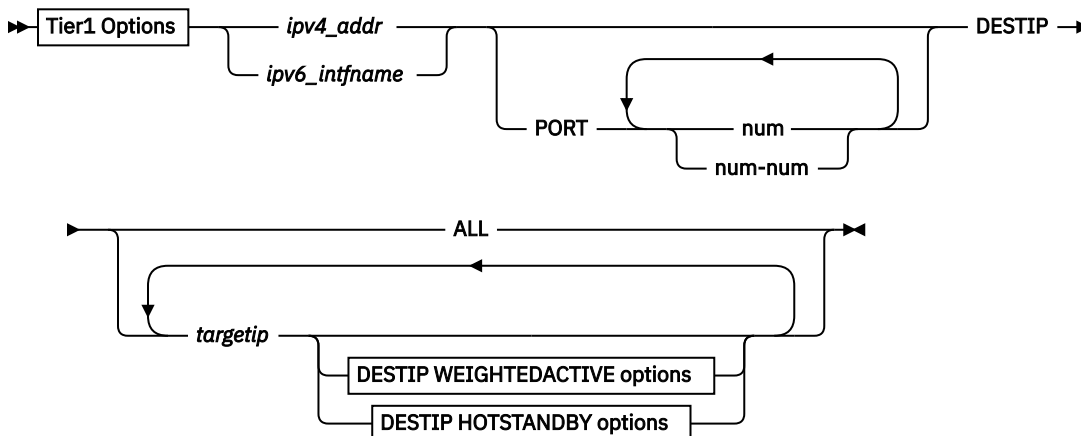

Base Parameters

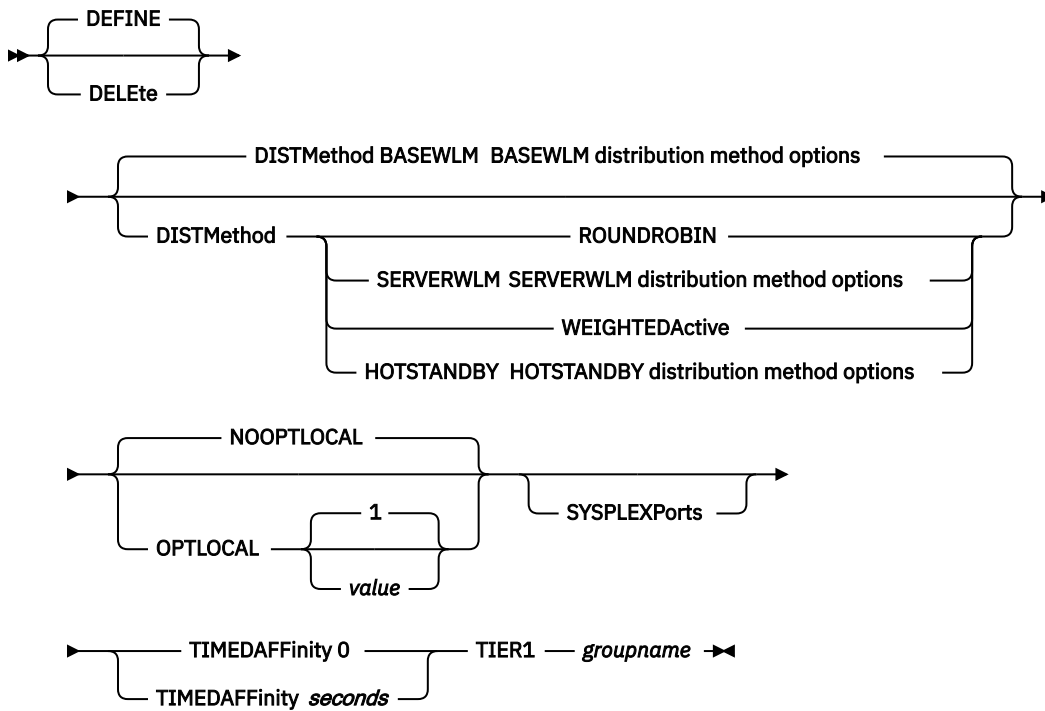

Base Options (These can be specified in any order)

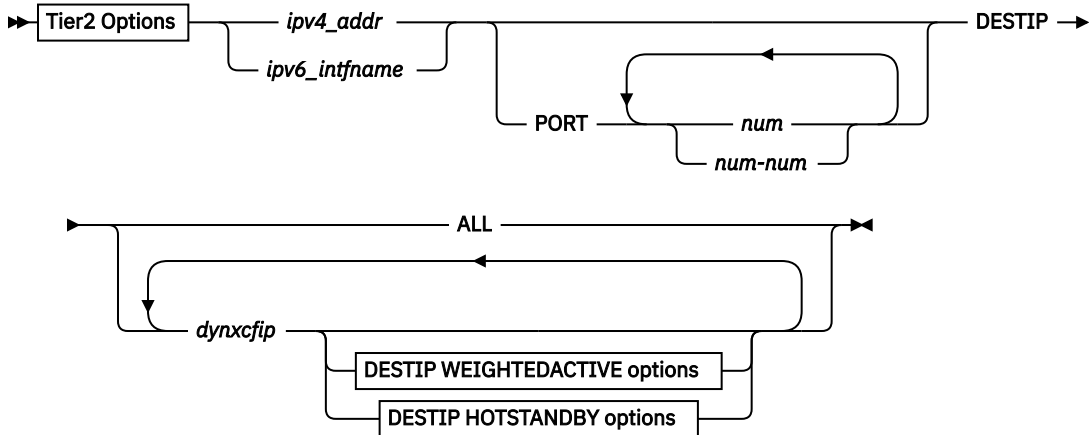

Tier1 Parameters

Tier1 Options (These can be specified in any order)

Tier2 Parameters

Tier2 Options (These can be specified in any order)

DESTIP WEIGHTEDACTIVE options

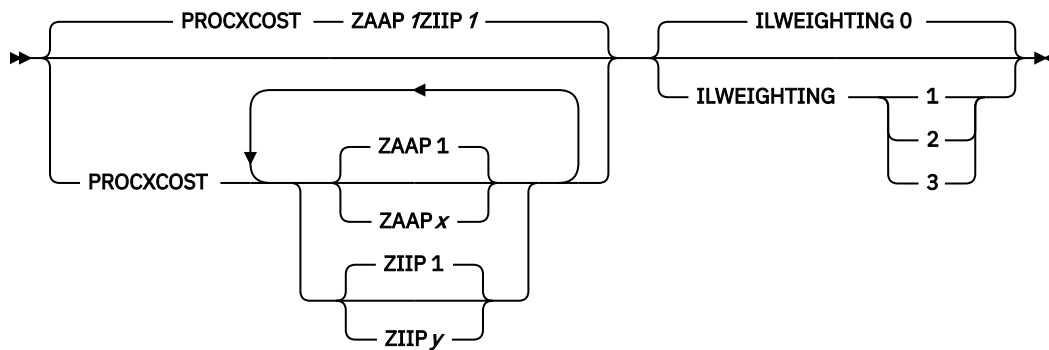

DESTIP HOTSTANDBY options

BASEWLM distribution method options

SERVERWLM distribution method options

HOTSTANDBY distribution method options

Parameters

DEFINE

Adds or replaces the designation of this dynamic VIPA (defined on the same stack by a VIPADefine or VIPABACKUP statement) as distributable. This is the default value.

DELETE

Deletes a previous designation of a dynamic VIPA as distributable.

DISTMETHOD

Specifies the distribution method to be used by the distributing stack.

BASEWLM

Specifies that Workload Manager (WLM) and policy information is used for this distributed DVIPA for incoming connection requests. Incoming connection requests are distributed according to relative WLM system weight preferences as modified by the Target Server Responsiveness (TSR) value, and possibly as modified by Service Policy Agent policies. The value DISTMETHOD BASEWLM is the default setting.

Rule: You must specify IPCONFIG SYSPLEXROUTING on all target systems to use this distribution method.

BASEWLM distribution method options:

PROCTYPE

This parameter is valid only when the distribution method is BASEWLM. zAAPs and zIIPs are specialty processors designed for specific application workloads. Some target applications can take advantage of these specialty processors. For workloads that use server-specific WLM weights, WLM typically returns a composite raw weight that takes into consideration how well the server is meeting its WLM goals with respect to the various types of processors the server is using. For workloads that use system-wide WLM recommendations, WLM is unaware of how a resource is utilizing the various processors. Instead, WLM returns a weight for each processor type that is based on the amount of displaceable capacity for this processor in the system as compared to the available capacity for this processor on the other target systems.

For applications that use specialty processors and receive WLM system weight recommendations, specify a PROCTYPE parameter to indicate the expected proportion of each type of processor that the target application's workloads should use. A composite recommendation is determined from these proportions. Each of the proportions should be expressed as a number in the range 0 - 99. Each proportion value is divided by the total to determine the processor usage pattern. To determine the processor proportions to configure, study your workload usage of assist processors by analyzing SMF records, using performance monitors reports, such as RMF, and so on.

Possible values include:

CP *x*

The proportion of the workload that uses conventional processors.

ZAAP *y*

The proportion of the workload that uses zAAP processors.

ZIIP *z*

The proportion of the workload that uses zIIP processors.

For example, the value PROCTYPE CP 5 ZAAP 0 ZIIP 3 specifies a processor usage pattern such that 5/8 of the application's CPU utilization uses conventional processors (CP), and 3/8 of the application's CPU utilization uses zIIP processors.

For example, the value PROCTYPE CP 60 ZAAP 30 ZIIP 10, would specify a processor usage pattern such that 60% uses conventional processors (CP), 30% uses zAAP processors, and 10% uses zIIP processors.

The value PROCTYPE CP 1 ZAAP 0 ZIIP 0 is the default value; this value is used when the PROCTYPE parameter has never been specified. The default value indicates that 100% of the conventional processor weight (CP) should be considered when determining the composite weight (the application's workload does not use zIIP or zAAP processors). This value also disables an existing PROCTYPE value.

Specifying the PROCTYPE parameter without any parameters is equivalent to specifying the default values; you can use this setting disable an existing PROCTYPE value.

Restriction: When processor types are specified, at least one type must be specified with a nonzero value.

ROUNDROBIN

Specifies that WLM and policy information are not used to determine how to route future incoming connection requests for this distributed DVIPA. Incoming TCP connection requests are distributed in a round-robin fashion across the available TCP/IP stacks that are targets for each DVIPA/port combination and have at least one application server instance listening on the specified ports. This distribution method is not influenced by the number of server instances that are active on a target TCP/IP stack instance and listening on the same port (for example, SHAREPORT specified on the PORT reservation statement). In other words, a target TCP/IP stack that has multiple active servers on the same port does not receive more connection requests than a target stack that has a single instance of that server active.

Result: If a distribution target has a Target Server Responsiveness (TSR) value of 0, it is normally not used as a target for distribution. For more information about [responsiveness monitoring](#), see [z/OS Communications Server: IP Configuration Guide](#).

SERVERWLM

Specifies that server-specific WLM values should be collected for this group of DVIPA ports. If WLM server values can be collected for each target server, these values are used to distribute connections for this group of DVIPA ports [as modified by the Target Server Responsiveness (TSR) value, and possibly as modified by Service Policy Agent policies]. If all target servers do not provide the server-specific recommendations, then DISTMETHOD BASEWLM distribution is used instead. For more information about [workload balancing and sysplex distribution](#), see [z/OS Communications Server: IP Configuration Guide](#).

Rule: You must specify IPCONFIG SYSPLEXROUTING on all target systems to use this distribution method.

Result: zAAP and zIIP processor capacity is automatically included when SERVERWLM is specified and all systems in the sysplex are V1R9 or later.

Port sharing

Specifying SHAREPORT on the PORT statement in the TCP/IP profile enables a group of servers to listen on the same port and thereby share the incoming workload. As new connections are

received, the SHAREPORT algorithm distributes connections in a weighted round-robin fashion based on each server's Server accept Efficiency Fraction (SEF). By specifying SHAREPORTWLM on the PORT statement, connections are distributed in a weighted round-robin fashion based on the WLM server-specific recommendations, as modified by the Server accept Efficiency Fraction (SEF). If the shared port is a sysplex-distributed port and SERVERWLM is the distribution method that is being used, then SHAREPORTWLM should be coded on each target's PORT statement to take advantage of the new WLM server-specific recommendations when connections are received at the target; if it is not, new connections continue to be distributed using the existing SHAREPORT algorithm when they are received at the target.

Result: zAAP and zIIP processor capacity is automatically included when SHAREPORTWLM is specified and all systems in the sysplex are V1R9 or later.

SERVERWLM distribution method options:

ILWEIGHTING

This parameter is valid only when the distribution method is SERVERWLM.

The ILWEIGHTING parameter specifies the weighting factor that WLM uses when comparing displaceable capacity at different importance levels (ILs) as it determines a SERVERWLM recommendation for each system. The parameter value indicates how aggressively WLM should favor systems with displaceable capacity at low importance levels over systems with displaceable capacity at high importance levels. The higher the value specified for ILWEIGHTING the more a stack with displaceable capacity at lower importance levels is favored. See the internal load balancing information in [z/OS Communications Server: IP Configuration Guide](#) for more information about the effects of this parameter.

0

WLM ignores importance levels when comparing displaceable capacity. This is the default value.

1

WLM weights displaceable capacity that is at each successively lower importance level slightly higher than the capacity at the preceding importance level. The weighting increases proportionally to the square root of the difference between the two importance level values plus 1. This calculation provides a moderate bias when comparing displaceable capacity at different importance levels.

Guideline: If you specify any value other than the default value (0), for the first time, specify this value (1) initially.

2

WLM weights displaceable capacity that is at each successively lower importance level significantly higher than the capacity at the preceding importance level. The weighting increases proportionally to the difference between the two importance level values plus 1. This provides an aggressive bias when comparing displaceable capacity at different importance levels.

3

WLM weights displaceable capacity that is at each successively lower importance level significantly higher than the capacity at the preceding importance level. The weighting increases proportionally to the square of the difference between the two importance level values plus 1. This provides an exceptionally aggressive bias when comparing displaceable capacity at different importance levels.

PROCXCOST

This parameter is valid only when the distribution method is SERVERWLM.

zAAPs and zIIPs are specialty processors designed to off-load specific application workloads. Some target applications are designed to have a portion of their workload take advantage of these processors.

For server-specific recommendations, WLM calculates a composite weight based on a comparison, for each system, of the available capacity of each processor modified by the

proportion of processor usage by the application. However, the composite weight does not consider that the conventional processor proportion on a system might be higher than normal because specialty processing capacity is constrained; a portion of the workload intended to run on a specialty processor ran on the conventional processor instead.

This parameter specifies a crossover cost which is applied to the zAAP or zIIP targeted workload that ran on the conventional processor; it reduces the conventional processor proportion which in turn reduces the composite weight for that system. This parameter can be used to cause WLM to favor systems that had less crossover (more of their workload running on the intended specialty processor) over systems that had more crossover. The higher the PROCXCOST crossover value, the more aggressively WLM recommendations favor systems with more specialty engine capacity which can reduce overall processing cost; however, if you use a PROCXCOST value that is too aggressive (high), overall workload performance for that service class might be sacrificed. The RMF Workload Activity Report shows the zAAP and zIIP processor utilization as well as how much crossover took place. Run this report before, and after, using the PROCXCOST parameter to better understand how this affects your overall workload performance.

Possible values include:

zAAP x

The crossover cost of running targeted zAAP workload on a conventional processor instead of the zAAP processor, where x is an integer in the range 1 - 100. The higher the PROCXCOST zAAP value, the more aggressively the systems with less zAAP crossover occurring are favored. The default value is 1, which means that zAAP crossover is not considered.

zIIP y

The crossover cost of running targeted zIIP workload on a conventional processor instead of the zIIP processor, where y is an integer in the range 1 - 100. The higher PROCXCOST zIIP value, the more aggressively the systems with less zIIP crossover are favored. The default value is 1, which means that zIIP crossover is not considered.

WEIGHTEDACTIVE

Specifies that WLM and policy information are not used to determine how to route future incoming connection requests for this distributed DVIPA. Instead, distribution of incoming TCP connection requests is balanced across the targets such that the number of active connections on each target is proportionally equivalent to a configured active connection weight for each target.

You can specify the weight for each target on the DESTIP parameter after each target's IP address. If you configure the value DESTIP ALL, then the default weight 10 is used and the connection distribution goal is to have an equal number of active connections for each DESTIP target. For more information, see the *DESTIP WEIGHTEDACTIVE options*.

This distribution method is not influenced by the number of server instances that are active on a target TCP/IP stack instance and listening on the same port (SHAREPORT parameter specified on the PORT reservation statement). For example, when two target TCP/IP stacks are configured with the same active connection weight, if one of the targets has multiple active servers for that port and the other target has only one instance of that server active, both stacks initially receive the same number of connection requests.

Rule: You must specify IPCONFIG SYSPLEXROUTING on all target systems to use this distribution method.

HOTSTANDBY

Specifies that there is at least one backup (hot-standby) target and a preferred target stack. You must configure one preferred target and at least one hot-standby target. For information about configuring these targets, see the PREFERRED and BACKUP parameters under *DESTIP HOTSTANDBY options*.

The target to which connections are distributed is referred to as the active target. If AUTOSWITCHBACK is configured, then the preferred target is the active target if it is available

and has not had any health problems. If the active target becomes unavailable, the hot-standby target becomes the new active target, and the unavailable target becomes a hot-standby target.

A target is unavailable if any of the following conditions are true:

- The target is not ready.
- The distributor does not have an active route to the target.
- The target is not healthy; there is a severe problem detected by one of the following health metrics:
 - The target server responsiveness (TSR) value is 0%
 - WLM reported abnormal terminations are 1000 out of 1000 total transactions
 - WLM reported health is 0%

Requirement: PREFERRED or BACKUP must be configured on the DESTIP parameter for each target after the dynamic XCF address. For more information, see the *DESTIP HOTSTANDBY options*.

Rule: IPCONFIG SYSPLEXROUTING must be specified on all target systems for this distribution method to be used.

Restrictions:

- You cannot configure DESTIP ALL with this distribution method.
- TIMEDAFFINITY is ignored with this distribution method.

Result: In the Netstat VDPT/-O report, ACTIVE is displayed if this is currently the active target, and BACKUP is displayed if this is currently a hot-standby target. For more information about the Netstat VDPT/-O report, see [z/OS Communications Server: IP System Administrator's Commands](#).

HOTSTANDBY distribution method options:

AUTOSWITCHBACK | NOAUTOSWITCHBACK

AUTOSWITCHBACK

Specifies that the distributor automatically switches distribution back to the preferred target when the preferred target becomes available. For example, if the preferred target becomes a standby target because its server is no longer ready, when the server is again in the LISTENING state, the distributor automatically switches back to the preferred target as the active target. This is the default value.

Automatic switchback does not occur if the preferred target initially became unavailable because it was not healthy (TSR, WLM abnormal terminations, WLM health). A standby target that had health problems while active can look healthy again because it is not processing new work.

NOAUTOSWITCHBACK

Specifies that you do not want the distributor to switch back to the preferred target when it becomes available.

HEALTHSWITCH | NOHEALTHSWITCH

HEALTHSWITCH

Specifies that the distributor automatically switches from the active target if the target is not healthy. This is the default value.

NOHEALTHSWITCH

Specifies that the distributor ignores health metrics, and switches from the active target only if the target is not ready or if the distributor does not have an active route to the target.

SYSPLEXPORTS

Causes coordinated sysplex-wide ephemeral port assignment to be activated for the distributed DVIPA on all stacks where the DVIPA is defined, including all active candidate target stacks and the distributing stack, for all TCP connection requests.

SYSPLXEXPORTS must be specified on the first VIPADISTRIBUTE statement for a DVIPA. It cannot be enabled after a DVIPA has been marked for distribution. If enabled, it cannot be disabled until all distribution has been deleted for the DVIPA (except for quiescing the DVIPA on the target stacks).

If you send connection requests to SYPLEXEXPORTS-enabled distributed DVIPAs and a random ephemeral port with no associated listener, then this connection times out.

Rules:

- For Passive Mode FTP to be distributed, the SYSPLXEXPORTS parameter must be specified.
- Always specify the PORT parameter when specifying the SYSPLXEXPORTS parameter; the way dynamic port allocation interacts with the EZBEPORT *vvtt* structure inhibits distribution to more than one target.
- A server application on a target stack can bind to a distributed DVIPA and a port that is not defined in the PORT parameter of the VIPADISTRIBUTE statement.
- If EPHEMERALPORTS is specified on the TCPCONFIG statement, only ports within the EPHEMERALPORTS range are assigned on the local stack for SYSPLXEXPORTS processing.

Restrictions:

- For sysplexports allocation to function correctly, the stacks involved must be connected to the same sysplex ports coupling facility structure.

EXTTARG

Specifies that this distributed DVIPA is used for external target distribution. This value is not specified by default. The only valid distribution method for a VIPADISTRIBUTE statement with the EXTTARG keyword is ROUNDROBIN.

Note: If the EXTTARG keyword is configured without the DISTMETHOD parameter, ROUNDROBIN will be set automatically.

EXTTARG must be specified on the first VIPADISTRIBUTE statement for a DVIPA. It cannot be enabled after a DVIPA has been marked for distribution. If enabled, it cannot be disabled until all distribution has been deleted for the DVIPA.

Guideline:

SRCIP DESTINATION statements will be created autonomically for EXTTARG DVIPAs if they are not manually configured. The autonomic SRCIP DESTINATION statements will use the IPCONFIG DYNAMICXCF IP address as the source IP address. This ensures local client applications will not use the distributed VIPA as the source IP address when connecting to a target with the distributed DVIPA.

For more information about [source IP selection](#), see [z/OS Communications Server: IP Configuration Guide](#).

For more information about the SRCIP statement, see [“SRCIP statement” on page 233](#).

Rules:

- The following options are supported for VIPADISTRIBUTE statements with the EXTTARG keyword:
 - DISTMETHOD ROUNDROBIN
- The OPTLOCAL base option is ignored with the EXTTARG keyword
- The TIMEDAFFINITY base option is ignored with the EXTTARG keyword
- The following options cannot be specified with the EXTTARG keyword and will cause the VIPADISTRIBUTE statement to be rejected:
 - DESTIP ALL
 - DESTIP ALL is only rejected in combination with a VIPADISTRIBUTE DEFINE. It is accepted with a VIPADISTRIBUTE DELETE.
 - DISTMETHOD other than ROUNDROBIN
 - IPv6 interface names

- SYSPLEXPORTS
- TIER1 or TIER2 parameters
- PORT
- PAUSE

PAUSE

Specifies the initial distribution state to be used by the distributing stack for this DVIPA and the configured port(s). This value is off by default. When enabled, sysplex distribution for new connection requests to the DVIPA and port(s) will result in the connection being reset. The VARY TCPIP,,SYSPLEX DISTRESume command can be used to resume sysplex distribution for the DVIPA and port(s). See [VARY TCPIP,,SYSPLEX](#) in [z/OS Communications Server: IP System Administrator's Commands](#) for more information.

PAUSE must be specified on the first VIPADISTRIBUTE statement for a DVIPA and port(s). It cannot be enabled after a DVIPA and port(s) have been marked for distribution. If enabled, it cannot be disabled until all distribution has been deleted for the DVIPA and port(s).

TIER1 *groupname*

This parameter indicates that the dynamic VIPA whose address is specified as an IP address on this statement is used to distribute incoming requests to z/OS targets.

Rules:

- The targets are z/OS targets and the IP addresses specified on the DESTIP subparameter of this statement are dynamic XCF addresses.

The *groupname* value specifies the name of a cluster of equivalent server applications in the sysplex that the tier 1 targets might distribute the requests to. The groupname value can be 1 - 16 characters in length, must begin with an alphabetic character, and must not contain any national symbols, including @ or \$. This value is used to correlate this statement with a corresponding TIER2 VIPADISTRIBUTE statement or statements. When TIER1 is specified, *groupname* is required, even if TIER2 definitions are not used.

TIER2 *groupname*

This parameter indicates that the dynamic VIPA whose address is specified as an IP address on this statement is used to distribute incoming requests from Tier 1 targets to the group of server applications that is named.

The *groupname* value specifies the name of a cluster of equivalent server applications in the sysplex that the Tier 1 targets might distribute the requests to. It is used to correlate this statement with a corresponding TIER1 VIPADISTRIBUTE statement.

The *groupname* value can be 1 - 16 characters in length, must begin with an alphabetic character, and must not contain any national symbols, including @ or \$.

TIMEDAFFINITY *seconds*

Specifies whether or not a connection from a client (as identified by source IP address) to a particular server instance of several served by sysplex distributor shall establish an affinity for future connections from the same client (IP address) to the same Distributed DVIPA and ports. Valid values are in the range 0 to 9999. A value of 0, the default, means that no affinity is established when a new connection request is distributed to a particular server application instance by sysplex distributor. A nonzero value means that when a connection from a client is routed to a particular server instance, any subsequent connections from the same client (identified by source IP address) to the same Distributed DVIPA and ports are routed to the same server instance until the specified number of seconds have elapsed after the last such connection was closed.

Restriction: Under some circumstances, a client's affinity with a specific target application server instance might be terminated prior to the specified time interval. This can occur if the key resources needed to satisfy new client TCP connection requests are not available. See [z/OS Communications Server: IP Configuration Guide](#) for more information.

If the TIMEDAFFINITY parameter is not initially specified on a VIPADISTRIBUTE statement, this indicates that timed affinity is not being used for the distributed DVIPA and ports, which is the same as specifying TIMEDAFFINITY 0.

Restriction: The TIMEDAFFINITY parameter cannot be specified with the OPTLOCAL keyword.

OPTLOCAL value | NOOPTLOCAL

NOOPTLOCAL

Causes target stacks to send locally originating connection requests to the sysplex distributor stack even when both endpoints reside on the same target stack. This is the default value.

OPTLOCAL value

Causes target stacks to optimize sysplex connections for which both endpoints reside on the same stack. When this value is specified, target stacks should bypass sending connection requests to the sysplex distributor stack for connections to a distributed DVIPA and port pair that reside locally, and instead process the connection locally using local optimizations. The local target stack continues to favor the local stack unless conditions on the local stack become unfavorable as defined by the value specified. If this happens, connections to this distributed DVIPA and port pair are sent to the sysplex distributor stack for appropriate work load balancing.

Restrictions:

- OPTLOCAL cannot be specified with the TIMEDAFFINITY keyword.

value

An integer in the range 0 - 16. The values 0 and 1 are special values, and values 2 - 16 are used as multipliers against the raw WLM weights.

A value of 0 indicates that connections originating from a target stack within the sysplex should always bypass sending the connection request to the sysplex distributor. The relative capacities of other target stacks within the sysplex are not considered in determining whether the connection should remain local.

A value of 1 indicates that connections originating from a target stack within the sysplex should always bypass sending the connection request to the sysplex distributor as long as the WLM weight for the server on the local stack is not 0. This is the default value if OPTLOCAL is specified without a value.

If a value in the range 2 - 16 is specified, the value is used as a multiplier against the local target stack's raw WLM weight to cause it to be favored over the other target stacks. The relative capacities of the other target stacks within the sysplex are considered in determining which stack should process the connection. The higher the value specified, the more the local stack is favored over other target stacks.

Regardless of the value specified on the OPTLOCAL parameter, if no local server is available, or the SEF is less than 75 or the abnormal transaction completions is greater than 250, or the health indicator is less than 75, connections are sent to the distributing stack.

Result: If the configured distribution method is ROUNDROBIN, WEIGHTEDACTIVE, or HOTSTANDBY, the OPTLOCAL value is forced to 0.

ipv4_addr

The specific IPv4 address for which the designation as distributable is to be deleted or defined.

ipv6_intfname

The specific IPv6 interface for which the designation as distributable is to be deleted or defined.

PORT num | num-num

Specifies one or more individual ports, ranges of ports, or a combination of individual ports and ranges. Valid values for *num* are in the range of 1 - 65535. For a port range, the value for the second port must be greater than the first.

If the PORT parameter is specified, servers that bind to the specified DVIPA, the IPv4 INADDR_ANY address, or to the IPv6 unspecified address (in6addr_any) and one of the specified ports, cause the target stack to become eligible to receive connection requests.

The PORT parameter can also be omitted entirely from the VIPADISTRIBUTE statement. If the PORT parameter is omitted, then any server that binds a socket to the distributed DVIPA and a specific (nonzero) port, and establishes that socket as a listening socket, is eligible for connection workload balancing. The following methods can be used to bind a socket to the distributed DVIPA and a specific (nonzero) port:

1. If available, use a socket option provided by the server application to override the INADDR_ANY address and to specify a distributed DVIPA address for the listening port.
2. Code a BIND parameter that specifies a distributed DVIPA for the listening port in the TCP/IP profile PORT statement.
3. Use the TCP/IP profile SRCIP statement to specify a job name for the server application, the distributed DVIPA address, and the SERVER option. The listening port for the server application will be associated with the distributed DVIPA address.

Rules:

- When the PORT parameter is omitted from the VIPADISTRIBUTE statement and a specific (nonzero) port is not specified on the bind for the distributed DVIPA, then any ports that are bound to the distributed DVIPA are eligible for distribution.
- When the PORT parameter is specified, at least one port or port range must be specified. The maximum number of ports that is specified, including all individual ports and all ports within ranges, cannot exceed 256.
- Always specify the PORT parameter when specifying the SYSPLEXPORTS parameter. For the ports omitted from the PORT parameter, connection setup delays and connection timeouts might occur when there are no active listeners in the target stacks.
- For the ports specified in the PORT parameter for a distributed DVIPA, reserve them in the PORT statement in all target stacks associated with the distributed DVIPA so that ineligible server applications will not use them.

DESTIP *dynxcfip*

Specifies the dynamic XCF address (IPCONFIG DYNAMICXCF) of the TCP/IP stacks in the sysplex that are to be target stacks for the dynamic VIPA. The target stacks are candidates for receiving new incoming connection requests. See the PORT keyword for an explanation of how a candidate target stack becomes eligible to receive connection requests. If the VIPAROUTE statement specifies a target IP address for *dynxcfip*, but no route exists from the distributor to the target stack, that target stack is not considered for distribution, and the distributor treats this as it does when the dynamic XCF interface becomes inactive.

A maximum of 32 destination (target) dynamic XCF addresses can be specified.

Rules:

- If an IPv4 address is specified for this VIPADISTRIBUTE statement, then all of the addresses specified by the *dynxcfip* value must also be IPv4 addresses.
- If an IPv6 interface name is specified for this VIPADISTRIBUTE statement, then all of the addresses specified by the *dynxcfip* value must also be IPv6 addresses.
- If the EXTARG keyword is configured for this VIPADISTRIBUTE statement, then all of the addresses specified by the *dynxcfip* value must be the IP addresses assigned to the external targets.

DESTIP *targetip*

When you specify TIER1, this parameter specifies the dynamic XCF address (IPCONFIG DYNAMICXCF) of the TCP/IP stacks in the sysplex that are to be target stacks for the dynamic VIPA. The target stacks are candidates to receive new incoming connection requests.

A maximum of 32 Tier 1 target IP addresses can be specified.

Rules:

- If an IPv4 address is specified for this VIPADISTRIBUTE statement, then all of the addresses specified by the *targetip* value must also be IPv4 addresses.
- If an IPv6 interface name is specified for this VIPADISTRIBUTE statement, then all of the addresses specified by the *targetip* value must also be IPv6 addresses.

DESTIP WEIGHTEDACTIVE options:

WEIGHT value

This parameter is configured following a DESTIP *targetip* or *dynxcfip* value.

This parameter has meaning only if the distribution method is WEIGHTEDACTIVE; it is ignored if this is not the distribution method. The weight is used by the distributor to determine the proportion of incoming requests to route to this target such that the number of active connections on each target is proportionally equivalent to the configured weight for each target. Valid values are in the range 1 - 99.

For example, if target 1 has a weight of 10 and target 2 has a weight of 90, then the connection distribution goal is to have 9 times as many active connections on target 2 as on target 1, or 10% of the active connections on target 1 and 90% of the active connections on target 2. If a weight is not specified, the default value of 10 is used. If the distribution method is WEIGHTEDACTIVE and weights are not configured for any targets, the goal is to have an equal number of active connections on each target.

Guidelines: Although weights can be in the range 1- 99, it is preferred to use weights that are greater or equal to 10. This is because the target server health metrics (Target Server Responsiveness [TSR] fractions) abnormal terminations, and the health indicator fractions are used to reduce the weight when these values are not optimal. By specifying weights greater than or equal to 10, these metrics can be applied without losing the original weight distinctions between targets. For example, if target 1 has a weight of 2, target 2 has a weight of 1, and a TSR for target 1 of 90% is applied, target 1 has a reduced weight of 1 (equal to target 2), but if target 1 has a weight of 20 and target 2 has a weight of 10, then when the TSR of 90% is applied to target 1, it has a weight of 18 (weight reduced, but it is still preferred over target 2).

If your workload has a low connection arrival rate (less than 100 connections per minute), and typically has a low number of active connections (less than 1000 active connections), you will get the most accurate distribution if you configure each weight so that it is a multiple of 10.

DESTIP HOTSTANDBY options:

PREFERRED

Specify this parameter after the dynamic XCF address (*dynxcfip*) on the DESTIP parameter. This parameter specifies that this address is the preferred target when the distribution method is HOTSTANDBY. If you configure AUTOSWITCHBACK, then the preferred target is the active target if it is available and has not had any health problems. If the active target becomes unavailable, the distributor switches to use a hot-standby target; the active target becomes a hot-standby target and the selected hot-standby target becomes the active target.

Restriction: You can specify this parameter only if you specify DISTMethod HOTSTANDBY.

BACKUP rank

Specify this parameter after the dynamic XCF address (*dynxcfip*) on the DESTIP parameter. This parameter specifies that this address is one of the backup targets when the distribution method is HOTSTANDBY.

The *rank* is used to determine which backup target is selected if the preferred target becomes unavailable. The backup with the highest rank is used. Valid values for *rank* are in the range 1 - 254; the default value is 1.

Restriction: You can specify this parameter only if you specify DISTMethod HOTSTANDBY.

DESTIP ALL

All TCP/IP stacks in the sysplex that have defined a dynamic XCF address of the same type as the IP address specified by the *ipv4_addr* or *ipv6_intfname* values in this VIPADISTRIBUTE statement are target stacks for the dynamic VIPA and for ports specified on this profile statement. If the distribution method WEIGHTEDACTIVE is being used, the default weight 10 is assumed for all targets; the goal is to have an equal number of active connections on each target.

Restrictions: .

- – DESTIP ALL cannot be specified when the distribution method is HOTSTANDBY.
- When DESTIP ALL or DESTIP dxcfaddr is specified, there is a limitation that only 32 targets can be used.

Steps for modifying

- To add ports (if the active VIPADISTRIBUTE statement has the PORT parameter coded) or destination stacks for a distributed DVIPA, use another VIPADISTRIBUTE statement to specify the additional port or ports and destination stacks. Ports and destination stacks for a distributed VIPA are cumulative, up to the maximum number allowed (256 for ports and 32 for destination stacks).
- To remove a port or a destination stack for IPv4, or both, for a distributed VIPA, use one of the following:

```
VIPADISTRIBUTE DELETE ipaddr PORT port_num ... DESTIP dynxcfp ...
```

```
VIPADISTRIBUTE DELETE ipaddr PORT port_num DESTIP ALL
```

For IPv6, use one of the following:

```
VIPADISTRIBUTE DELETE ipv6_intfname PORT port_num ... DESTIP dynxcfp
```

```
VIPADISTRIBUTE DELETE ipv6_intfname PORT port_num DESTIP ALL
```

- To end distribution for a VIPA, use one or more VIPADISTRIBUTE DELETE statements to delete every port and destination stack that is currently configured for this VIPA. These changes are communicated to any stacks backing up the distribution of this DVIPA, unless the backup stack has its own VIPADISTRIBUTE statement coded.
- If ports are currently assigned for distribution dynamically for this Distributed DVIPA (PORT parameter omitted from the VIPADISTRIBUTE DEFINE), then VIPADISTRIBUTE DELETE can be used only to stop distribution for a target TCP/IP or for the Distributed DVIPA as a whole. VIPADISTRIBUTE DELETE cannot be used to stop distribution for a port with a Distributed DVIPA where ports are added dynamically.
- To specify certain ports for distribution when a distributed DVIPA is allowing distribution ports to be assigned dynamically (the active VIPADISTRIBUTE statement has no PORT parameter), you must first delete the VIPADISTRIBUTE statement (without PORT parameter). You can then code a VIPADISTRIBUTE statement with the PORT parameter. Existing connections to server instances are not affected. However, a server listening socket bound to a port which is not in the current PORT statement does not receive additional work.
- To allow dynamic port specification by having servers listening on ports when the active VIPADISTRIBUTE statement has a PORT parameter coded, you must first delete the VIPADISTRIBUTE statement (with PORT parameter). You can then code a VIPADISTRIBUTE statement without the PORT parameter. Existing connections are not affected. Note that when the VIPADISTRIBUTE statement is specified without the PORT parameter, only servers that bind explicitly to the distributed DVIPA are eligible for workload distribution for that distributed DVIPA.
- To modify the OPTLOCAL option on the VIPADISTRIBUTE statement, respecify the VIPADISTRIBUTE statement with the new option value in a data set referenced by a VARY TCPIP,,OBEYFILE command. You can specify NOOPTLOCAL to dynamically stop OPTLOCAL processing.

- If the value TIMEDAFFINITY 0 is specified for a distributed DVIPA and ports for which a nonzero TIMEDAFFINITY value was in effect, no future affinities are established for new clients connecting to the distributed DVIPA and ports covered by the VIPADISTRIBUTE statement. Existing client affinities are not affected.
- If a nonzero TIMEDAFFINITY value is specified for an existing distributed DVIPA with active connections, affinities are established only for connections that are received at the distributing stack after the processing of the VARY TCPIP,,OBEYFILE command that established the nonzero TIMEDAFFINITY value. Existing connections do not automatically have an affinity established for the respective client.
- To change the distribution method being used, respecify the VIPADISTRIBUTE statement with the new DISTMETHOD option in a data set referenced by a VARY TCPIP,,OBEYFILE command. If the new distribution method is WEIGHTEDACTIVE:
 - Specify the WEIGHT keyword and the desired active connection weight value after each DESTIP dynamic XCF address.
 - If the active connection weight is not specified a default value of 10 is assumed.
 - If DESTIP ALL is specified, the active connection weight cannot be specified. A goal of having an equal number of active connections on all targets is used.
- To change the active connection weights being used for the targets when the distribution method is WEIGHTEDActive, in a data set referenced by a VARY TCPIP,,OBEYFILE command, respecify the VIPADISTRIBUTE statement with the WEIGHT keyword and the desired active connection weight value following each DESTIP dynamic XCF address. If the active connection weight is not specified, a default value of 10 is assumed.
- To change the PROCTYPE values being used with BASEWLM, in a data set referenced by a VARY TCPIP,,OBEYFILE command, respecify the VIPADISTRIBUTE statement with the PROCTYPE values for each processor type. If PROCTYPE is not specified, the previous values for PROCTYPE are used.
- To stop using PROCTYPE values, in a data set referenced by a VARY TCPIP,,OBEYFILE command, respecify the VIPADISTRIBUTE statement with the PROCTYPE values of CP 1 zAAP 0 zIIP 0, or simply PROCTYPE. This is the default usage of BASEWLM; only the general CPU weight that is returned by WLM is considered.
- To change the PROCXCOST values that are being used with SERVERWLM respecify the VIPADISTRIBUTE statement with the PROCXCOST values for each processor type in a data set referenced by a VARY TCPIP,,OBEYFILE command. If PROCXCOST is not specified, then the TCP/IP stack uses the previous values for PROCXCOST when it receives a server-specific WLM recommendation.
- To change the ILWEIGHTING value being used with SERVERWLM, respecify the VIPADISTRIBUTE statement with the ILWEIGHTING value in a data set referenced by a VARY TCPIP,,OBEYFILE command. If ILWEIGHTING is not specified, then TCP/IP stack uses the previous values for ILWEIGHTING when it gets a server-specific WLM recommendation.

Examples

```
VIPADefine 255.255.255.192 9.67.240.02
VIPADISTRIBUTE
  DISTMETHOD SERVERWLM 9.67.240.02 PORT 10000 DESTIP ALL

VIPADefine TIER2 CPCSCOPE V6DVIPA1 2000::9:67:240:2/96
VIPADISTRIBUTE
  DISTMETHOD SERVERWLM PROCXCOST ZIIP 2 ZAAP 2 ILWEIGHTING 2
  TIER2 LOCALGROUP OPTLOCAL 1 SYSPLXEXPORTS
  V6DVIPA1 PORT 10000 DESTIP ALL
```

VIPADYNAMIC - VIPARANGE statement

Defines or deletes a subnet for which dynamic VIPA (DVIPA) activation requests, by way of a BIND, SIOCSVIPa IOCTL, or SIOCSVIPa6 IOCTL are honored. For guidance on defining this statement, see the [APF-authorized application instance \(ioctl\) information and movement of unique application-instance \(BIND\) information in z/OS Communications Server: IP Configuration Guide](#).

Guidelines:

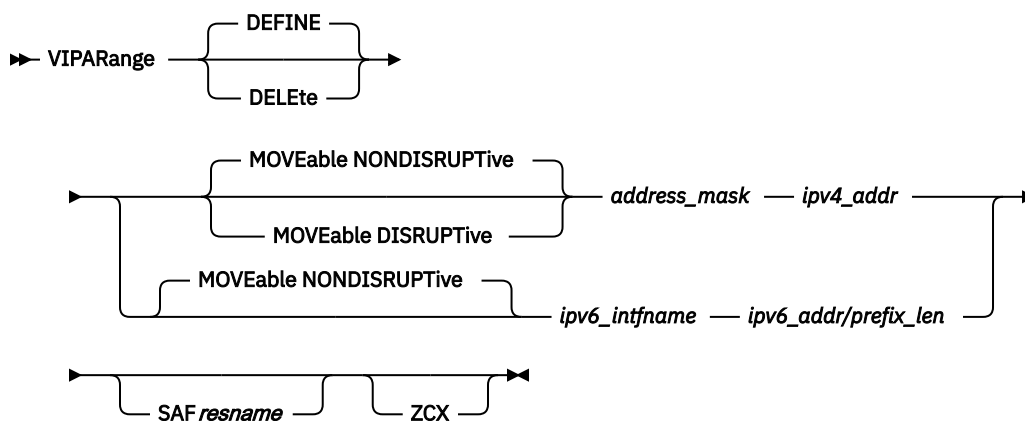

- VIPARANGE statements that are common to more than one stack should be defined in a common file and included in the appropriate stack profiles. This can help you avoid keying errors that could result in a failure to activate an application on a stack.
- Ensure that the DVIPAs (by IP address or subnet) in the VIPARANGE statements do not overlap the non-DVIPAs in the sysplex such that the created DVIPAs can appear as duplicate IP addresses. It is best to define the DVIPAs by IP address in the VIPARANGE statements when the DVIPAs are in the same subnet as the non-DVIPAs across the stacks in a sysplex. This can help you avoid potential network connectivity outages on network access interfaces where a registered non-DVIPA in one stack can get overridden by the created DVIPA with a duplicate IP address for a different stack upon registration.

Rule: For any DVIPA creation request, the most specific VIPARANGE statement match (IP address and subnet) is used.

Restriction: Up to 4096 VIPARANGE statements can be defined to one stack.

Syntax

Rule: Specify the parameters in the order shown here.

Parameters

DEFINE

Specifies that this definition is to be added to the list of defined VIPARANGE definition statements. This is the default value.

DELETE

Specifies that this definition (with the same *address_mask* and *ipv4_addr* values or the same *ipv6_intfname* and *ipv6_addr/prefix_len* values) is to be removed from the list of allowable ranges for IOCTL or BIND implicit dynamic VIPA activation.

Tip: A VIPARANGE DELETE statement does not affect currently existing dynamic VIPAs in the range being deleted.

MOVEABLE NONDISRUPTIVE

Specifies an immediate nondisruptive movement of a dynamic VIPA from one stack to another stack. This value indicates that a dynamic VIPA in this VIPARANGE statement can be moved to another stack when that stack requests ownership of the DVIPA as the stack creates it; this occurs when an application binds to that DVIPA, the MODDVIPA utility is used to create the DVIPA through the SIOCSVIPAs or SIOCSVIPAs6 ioctl, or the application directly issues the SIOCSVIPAs or SIOCSVIPAs6 ioctl. The new owning stack forwards packets for any existing connections to the original stack in order that the existing connections are not disturbed. All new connection requests are directed to the new owning stack. The NONDISRUPTIVE option is the only option supported for IPv6 addresses and is the default value for IPv4 addresses.

MOVEABLE DISRUPTIVE

Indicates that nondisruptive movement does not occur for dynamic VIPAs created within this range on this stack. This option is not supported for IPv6.

A subsequent BIND on another stack for the same VIPA address fails. The VIPA on the original stack remains unchanged.

A subsequent SIOCSVIPA ioctl on another stack succeeds, and the VIPA on this stack is deleted. Any connections to the VIPA on this stack are broken.

address_mask

Provides the subnet mask that, when logically ANDed with the *ipv4_addr* value, determines the VIPARANGE subnet.

The address mask is specified in standard dotted decimal format for IP addresses. The *address_mask* variable is used only for IPv4. A subnet mask of 0.0.0.0 is not valid.

Rules: This value must meet the normal mask definition rules:

- When converted to binary, the most significant bit must be a 1.
- When converted to binary, all bits less significant than (to the right of) the first 0 encountered from the left must also be 0.

In other words, the IP addresses in the subnet must be a single contiguous range of IP addresses.

ipv4_addr

This determines a VIPARANGE subnet value when ANDed with the specified address mask. Any dynamic VIPA that is requested by way of IOCTL or by BIND to a specific address must match a defined VIPARANGE subnet value, after the dynamic VIPA has been logically ANDed with the corresponding address mask. The network address or network ID of the VIPARANGE subnet, which is the lowest possible address in the range, is excluded. The broadcast address of the VIPARANGE subnet, which is the highest address in the range, is also excluded.

ipv6_intfname

The interface name is used only for IPv6. This interface name is used for each DVIPA defined by this VIPARANGE statement.

ipv6_addr

This determines a VIPARANGE subnet value when used with the *prefix_len* value. Any dynamic VIPA that is requested by way of IOCTL or by BIND to a specific address must match a defined VIPARANGE subnet value, after the dynamic VIPA has been logically ANDed with the corresponding network prefix. The network address or network ID of the VIPARANGE subnet, which is the lowest possible address in the range, is excluded. The highest address in the range is also excluded.

/prefix_len

The number of bits in the *ipv6_addr* value defines the prefix. The range is 1 - 128.

SAF rename

Specifies the final qualifier of a System Authorization Facility (SAF) resource name. An application can create a dynamic VIPA in the specified VIPARANGE subnet if the user ID that is associated with the application is given READ access to the resource. The maximum length for the *rename* value is 8 characters.

Restriction: You can not specify a 1-character value of 0 (zero) for *rename*.

For an application to create a dynamic VIPA in the VIPARANGE subnet, the user ID associated with the application must have access to the appropriate SAF resource:

- For an application that issues a bind socket call, the user ID must have READ access to the resource EZB.BINDDVIPARANGE.sysname.tcpname.rename.
- For an application:
 - that issues a SIOCSVIPA or SIOCSVIPA6 ioctl call or
 - that invokes the MODDVIPA utility (which issues the SIOCSVIPA or SIOCSVIPA6 ioctl call on behalf of the user) or

- that is a container image (for example, Podman or Kubernetes) running within the z/OS Container Platform (zOSCP)

The user ID must have READ access to the resource EZB.MODDVIPA.*sysname.tcpname.resname*.

where:

- EZB.BINDDVIPARANGE and EZB.MODDVIPA are constant
- *sysname* is the value of the MVS &SYSNAME. system symbol
- *tcpname* is the name of the procedure used to start the TCP stack
- *resname* is the 1-8 character resource name that follows the SAF keyword on the VIPARANGE statement
- For an application: - - -

Results:

- If the SAF keyword is specified and the user ID has READ access to the resource, the bind or ioctl call is processed.
- If the SAF keyword is specified and the user ID does not have READ access to the resource, the bind or ioctl call fails.
- If the SAF keyword is specified and the resource profile is not defined, the bind or ioctl call fails.
- Generic profiles are handled in the following ways:
 - All of the following profile specifications that include wildcard values match the EZB.BINDDVIPARANGE.*sysname.tcpname.resname* resource profile name:
 - EZB.BINDDVIPARANGE.*.*
 - EZB.BINDDVIPARANGE.**
 - EZB.BINDDVIPARANGE.*.*.*
 - All of the following profile specifications that include wildcard values match the EZB.MODDVIPA.*sysname.tcpname.resname* resource profile name:
 - EZB.MODDVIPA.*.*
 - EZB.MODDVIPA.**
 - EZB.MODDVIPA.*.*.*

The most specific match to a resource profile is always used.

For more information about defining a security profile for SIOCSVIPA, SIOCSVIPA6, and MODDVIPA and about defining a security profile for binding to DVIPAs in the VIPARANGE statement, see [z/OS Communications Server: IP Configuration Guide](#).

ZCX

This indicates that this VIPARANGE is to be reserved for use by z/OS Container Extensions function. Dynamic VIPAs within this VIPARANGE subnet cannot be created by any other application by way of a BIND, SIOCSVIPA IOCTL, SIOCSVIPA6 IOCTL, or MODDVIPA utility. For more information about z/OS Container Extensions, see [z/OS Communications Server: IP Configuration Guide](#).

Tip: Avoid configuring VIPARANGE statements with ZCX from overlapping with VIPARANGE subnets without the ZCX keyword.

Restriction: Dynamic VIPAs created from the VIPARANGE subnet with ZCX will not move from one stack to another stack. The MOVEable parameter is ignored.

Steps for modifying

- To remove a VIPARANGE statement, use one of the following:

```
VIPARANGE DELETE mask ipv4_addr
```

```
VIPARANGE DELETE ipv6_intfname ipv6_addr/prefix_len
```

- To change the subnet for a VIPARANGE statement, use one of the following two methods:

- To replace the subnet, use one of the following:

```
VIPARANGE DELETE original_mask original_ipv4_addr  
VIPARANGE new_mask new_ipv4_addr
```

```
VIPARANGE DELETE ipv6_intfname ipv6_addr/prefix_len  
VIPARANGE ipv6_intfname ipv6_addr/new_prefix_len
```

- To enlarge the subnet, use one of the following:

```
VIPARANGE mask2 ipv4_addr2
```

```
VIPARANGE ipv6_intfname ipv6_addr/prefix_len2
```

This configures a VIPARANGE statement where *mask2* ANDed with *ipv4_addr2* determines a subnet that overlaps or includes the original one.

Alternatively, you can enlarge the subnet by using one of the following:

```
VIPARANGE mask2 ipaddr2
```

```
VIPARANGE ipv6_intfname ipv6_addr/prefix_len2
```

This configures a VIPARANGE statement where *mask2* ANDed with *ipaddr* determines a subnet that overlaps or includes the original subnet.

- The value of ZCX, ZContainer , or ZCPA for a VIPARANGE statement cannot be changed without first removing the existing VIPARANGE statement and then redefining it.

Examples

```
VIPARANGE DEFINE 255.255.255.0 10.10.10.1  
VIPARANGE DEFINE 255.255.255.255 10.10.10.210 SAF APPL1  
VIPARANGE DEFINE 255.255.255.255 10.10.10.211 SAF APPL2  
VIPARANGE 255.255.255.0 9.67.240.0  
VIPARANGE V6DVIPARANGE 2000::9:67:270:0/112
```

VIPADYNAMIC - VIPAROUTE statement

A VIPAROUTE statement is used to select a route from a distributing stack or a backup distributing stack to a target stack. This route is used for distribution of all DVIPAs for which a matching dynamic XCF address, or ALL, was specified on a VIPADISTRIBUTE statement. This route is also used for forwarding packets to existing connections on a stack that contains the DVIPA in MOVING status. When processing a connection from the client, the sysplex distributor determines whether or not a matching VIPAROUTE statement has been specified. If it has, the best available route is determined using the normal IP routing tables. If no matching VIPAROUTE statement exists for that target, IP packets distributed by sysplex distributor to that target use dynamic XCF interfaces. Dynamic XCF interfaces include HiperSockets (iQDIO), IUTSAMEH for the same LPAR, or XCF interfaces created by the IPCONFIG DYNAMICXCF or IPCONFIG6 DYNAMICXCF statement.

Rule:

- Ensure that the MTU value on the routes that are to be used is at least 604 (specify 1308 for IPv6). Lower MTU values can impact network performance and might result in loss of connections.

Result: There is always a matching route (and thus no message) if you define a default route by specifying DEFAULT.

If the VIPAROUTE statement specifies a target IP address for which no route exists, an informational message is issued the first time the problem is encountered. When this happens, that target is not considered for the distribution, and the distributor treats this the same way as when the dynamic XCF interface becomes inactive. If OMPROUTE is used for dynamic routing on the target, the GLOBALCONFIG SYSPLEXMONITOR DELAYJOIN TCP/IP profile option should be considered. The DELAYJOIN option delays the processing of sysplex-related definitions within the TCP/IP profile statements until OMPROUTE is active.

In the following cases, even though a VIPAROUTE statement has been specified, the dynamic XCF interface is used for distribution:

- A target IP address that is not owned by the target stack is specified
- The defined dynamic XCF address is for a pre-V1R7 target stack

Messages are issued at the distributing stack when these conditions are detected, and when the distributing stack first attempts to route a connection request to the target stack.

An additional case where the dynamic XCF interface is used even though the VIPAROUTE parameter has been specified is for a connection that is protected by an IPSec UDP-encapsulated security association negotiated with a peer behind a NAT.

Syntax

Rule: Specify the parameters in the order shown here.

Parameters

DEFINE

Specifies that sysplex distributor should use the target IP address (*target_ipaddr*) to find the best available route to reach the target stack defined by the *dynxcfip* parameter. The target IP address can be any address in the HOME list of the target stack except for a dynamic VIPA (DVIPA) or a loopback address.

DELETE

Specifies that a previously defined VIPAROUTE statement should be deleted. sysplex distributor processing for the target stack specified by the *dynxcfip* parameter reverts to using dynamic XCF interfaces for existing and new connections after approximately 60 seconds.

dynxcfip

Specifies the IPv4 or IPv6 dynamic XCF address that uniquely identifies a target stack. The address is defined with an IPCONFIG DYNAMICXCF or IPCONFIG6 DYNAMICXCF statement on that target stack.

If duplicate *dynxcfip* values are specified (with different *target_ipaddr* values) with the DEFINE function in the same profile, the first entry is in effect. Any duplicate entries are ignored and a message is displayed.

See “Restrictions on IPv6 addresses configured in the TCP/IP profile” on page 83 for a list of restrictions that must be observed when specifying this parameter for IPv6 dynamic XCF addresses.

target_ipaddr

Specifies any fully qualified IPv4 address (in dotted-decimal format) or fully qualified IPv6 address (in colon-hexadecimal format) in the HOME list of the target stack except for a dynamic VIPA (DVIPA) or a loopback address. The value is a static VIPA, a dynamic XCF address, or a real IPv4 or IPv6 address associated with a physical interface. See “Restrictions on IPv6 addresses configured in the TCP/IP profile” on page 83 for a list of restrictions that must be observed when specifying this parameter for IPv6 addresses. This IP address is used as a destination address for a target stack to obtain the best available route from the sysplex distributor to the target stack.

Specifying a static VIPA for this address might achieve the highest degree of fault tolerance. This alleviates the single point of failure issue with non-VIPAROUTE statement use of dynamic XCF interfaces. If an IP address is specified that is not owned by the target stack, dynamic XCF interfaces are used to distribute IP packets to this target stack.

For more information about [the use of the routing information](#), see [z/OS Communications Server: IP Configuration Guide](#).

Steps for modifying

- To remove the current configured statement, specify the VIPAROUTE DELETE statement with the same *dynxcfip* value and the same *target_ipaddr* value in a configuration data set referenced by a VARY TCPIP,,OBEYFILE command.
- To change the current configured statement, you must specify the VIPAROUTE DELETE statement with the same *dynxcfip* value and the same *target_ipaddr* value first, and then specify the VIPAROUTE DEFINE statement with the same *dynxcfip* value and the different *target_ipaddr* value referenced by a configuration data set on a VARY TCPIP,,OBEYFILE command.
- If the VIPAROUTE statement is changed, it affects active as well as new connections. For example, if an active connection is being distributed across dynamic XCF interface, and a VIPAROUTE DEFINE statement is defined for that target which results in the distributor selecting a route to the target over a different interface, then the active and new connections begin to use that new interface after approximately 60 seconds. If the previously defined VIPAROUTE statement is deleted, then active and new connections begin to use dynamic XCF interfaces after approximately 60 seconds.

Examples

This example shows how to define an alternate route to dynamic XCF for the sysplex distributor function.

```
VIPAROUTE 201.3.10.10 199.3.10.1  
VIPAROUTE 2001:0DB8::201:3:10:10 2001:0DB8::199:3:10:1
```

Chapter 3. TCP/IP cataloged procedure (TCPIPROC)

If you need to customize TCPIPROC, see the [configuration information](#) and [configuration information](#) in [z/OS Communications Server: IP Configuration Guide](#).

Copy the TCP/IP cataloged procedure in SEZAINST(TCPIPROC) to your system or recognized PROCLIB and modify it to suit your local conditions. Specify TCPIP parameters and remove or change the DD statements as required. The job name associated with the started task of the TCP/IP system address space must match the NAME parameter on the SUBFILESYSTYPE statement in the BPXPRMxx member of PARMLIB used to start z/OS UNIX.

Configuring the stack for IPv6 is done in BPXPRMxx. For more information about configuring the stack to support IPv6, see [z/OS Communications Server: IP Configuration Guide](#) or [z/OS Communications Server: IPv6 Network and Appl Design Guide](#).

The TCP/IP cataloged procedure is used to specify parameters and define input/output files to be used by the stack. One of the main input data sets defined in the cataloged procedure is the Profile data set. This data set is defined by the PROFILE DD statement.

Specifying TCP/IP address space parameters

Parameters are specified in the PARM= field of the cataloged procedure's EXEC JCL statement. The values specified in this field can be any of the following ones:

Stack initial component trace parameters

The following parameters configure stack tracing at initialization time:

- CTRACE(CTIEZBxx) or TRC=xx can be specified to identify the CTIEZBxx member of SYS1.PARMLIB, which contains the SYSTCPIP Component Trace (CTRACE) options. If neither parameter is specified, the default member CTIEZB00 is used.
- IDS=xx can be specified to identify the CTIIDSxx member of SYS1.PARMLIB, which contains the SYSTCPIS Component Trace (CTRACE) options. If this parameter is not specified, the default member CTIIDS00 is used.

Language Environment® runtime options and environment variables

These values are used by the stack's Language Environment functions:

- Configuration
- Autolog
- SNMP TCP/IP Subagent

For example, the TCP/IP stack's configuration function uses the z/OS UNIX search order to locate TCPIP.DATA information to determine the stack's host name. See the [search orders used in the z/OS UNIX environment](#) in the [z/OS Communications Server: IP Configuration Guide](#) for a description of this search order. Use the RESOLVER_CONFIG environment variable in the PARM= field of the TCP/IP cataloged procedure to specify the TCPIP.DATA file or data set that you want the configuration function to use.

Stack Configuration task tracing parameter, -d or -D

This parameter enables tracing of Configuration task processing before the ITRACE ON CONFIG 1 Profile statement is processed.

Requirement: If this parameter is specified, then it must be the last parameter specified in the PARM= field, and it must be preceded by a slash as in the following example:

```
//TCPIP EXEC PARM=('&PARMS',  
// 'ENVAR("RESOLVER_CONFIG=/' 'TCPIVP.TCPPARMS(TCPDATA) '")'  
// '/' -d')
```

This trace can be disabled by way of a VARY TCPIP,,OBEYFILE command with ITRACE OFF CONFIG statement specified in the data set referenced by the command.

Example of a TCP/IP cataloged procedure

The following code is an example of a TCP/IP cataloged procedure that defines the component tracing and intrusion detection services tracing that is to be in effect for the TCP/IP address space.

```
//TCPIP    PROC PARMS='CTRACE(CTIEZB00),IDS=00'
//*TCPIP    PROC PARMS='TRC=00,IDS=00'
//*
//* z/OS Communications Server
//* SMP/E Distribution Name: EZAEB01G
//*
//* Licensed Materials - Property of IBM
//* 5650-Z05
//* Copyright IBM Corp. 1991, 2013
//* Status = CSV2R1
//*
//* SET PARM1=TCPIVP.TCPPARMS(TCPDATA)
//*
//TCPIP    EXEC PGM=EZBTCPIP,REGION=0M,TIME=1440,
//          PARM='&PARMS'
//* Uncomment the SET statement above when using the next two lines.
//* PARM=('&PARMS',
//       'ENVAR("RESOLVER_CONFIG=/'&PARM1'")')
//*
//* See the TCP/IP cataloged procedure chapter of the IP Configuration
//* Reference for a description of the parameters that can be
//* specified in the PARM= field of the EXEC statement.
//*
//*****
//* The C runtime libraries should be in the system's link list
//* or add them via a STEPLIB definition here. If you add
//* them via a STEPLIB, they must be APF authorized with DISP=SHR
//*
//*STEPLIB DD ...
//* Any data set referenced by the STEPLIB DD statement must be

```

Figure 3. Sample TCP/IP start up proc

Using output data sets

In the TCP/IP address space, the SYSPRINT and SYSERROR data sets defined with a DD statement must have a variable blocked (VB) format. Block size (BLKSIZE) for a VB RECFM must be at least 4 bytes larger than the logical record length (LRECL).

Guideline: You can allocate these as partitioned or sequential data sets, but be aware that partitioned data sets cannot be reused if they have filled or if the members already exist.

Chapter 4. Protocol number and port assignments

The protocol file or data set is used to map protocol names to protocol numbers. Some applications use `getprotobyname()` and other socket calls to look up protocol numbers or names. If the protocol file or data set is not present or does not contain the required definitions, certain applications might not function properly.

The sample protocol file or data set provided with z/OS Communications Server and shown in the following example contains the definitions required by most applications. See [Chapter 1, “Configuration data sets and files,”](#) on page 1 for information about the search order used by the resolvers for locating this file or data set.

Guideline: Keep both *hlq.ETC.PROTO* and */etc/protocol* in sync.

Figure 4. */etc/proto* or *ETC.PROTO* example

Port assignments

Port numbers are used on various socket calls. They are also included in both the header of a TCP segment and a UDP datagram. You can assign port numbers to your own server applications by adding entries to the z/OS UNIX file or to the data set.

Guidelines:

- Assign ports is by assigning a standard port number and use the Server Bind Control function of the `PROFILE.TCPIP PORT` statement to assign each server to a separate IP address.

- Use the IP address on the PORT BIND be a VIPA address known to the domain name server (DNS) as a host name that users understand. For example, the RXSERVE procedure is assigned to ports 512 and 514, the orexecd and orshd daemons are assigned to ports 512 and 514, and two IP addresses (host names MVS97 and MVS97USS) 9.67.113.1 and 9.67.113.2 are available.

The following example reflects a situation where more than one application needs to listen on the same port, and the application or applications bind to INADDR_ANY.

In this example, the PORT statement would be as follows:

```
PORT
512 TCP RXSERVE ; Remote Execution Server (default)
512 TCP OMVS BIND 9.67.113.2 ; orexecd Remote Execution Server (MVS97USS)
514 TCP RXSERVE ; Remote Shell Server (default)
514 TCP OMVS BIND 9.67.113.2 ; orshd Remote Shell Server (MVS97USS)
```

Result: Clients who use MVS97 for remote execution get RXSERVE, and clients who use MVS97USS get OMVS orshd.

PROFILE.TCPIP port assignments

Use the PORT and PORTRANGE statement in the PROFILE.TCPIP data set to reserve ports for specified user IDs, procedures, and job names.

Tip: The following example was used for test configuration and is for illustration only. The example shows a portion of SEZAINST(SAMPPROF), which contains the most current assignments.

```
;
PORT: Reserves a port for specified job names
;
; - A port that is not reserved in this list can be used by any user.
;   If you have TCP/IP hosts in your network that reserve ports
;   in the range 1-1023 for privileged applications, you should
;   reserve them here to prevent users from using them.
;   The RESTRICTLOWPORTS option on TCPCONFIG and UDPCONFIG will also
;   prevent unauthorized applications from accessing unreserved
;   ports in the 1-1023 range.
;
; - A PORT statement with the optional keyword SAF followed by a
;   1-8 character name can be used to reserve a PORT and control
;   access to the PORT with a security product such as RACF.
;   For port access control, the full resource name for the security
;   product authorization check is constructed as follows:
;   EZB.PORTACCESS.sysname.tcpname.safname
;   where:
;     EZB.PORTACCESS is a constant
;     sysname is the MVS system name (substitute your sysname)
;     tcpname is the TCPIP jobname (substitute your jobname)
;     safname is the 1-8 character name following the SAF keyword
;
;   When PORT access control is used, the TCP/IP application
;   USERID that is authorized to the resource. The resources
;   are defined in the SERVAUTH class.
;
;   For an example of how the SAF keyword can be used to enhance
;   security, see the definition below for the FTP data PORT 20
;   with the SAF keyword. This definition reserves TCP PORT 20 for
;   any jobname (the *) but requires that the FTP user be permitted
;   by the security product to the resource:
;   EZB.PORTACCESS.sysname.tcpname.FTPDATA in the SERVAUTH class.
;
; - The BIND keyword is used to force a generic server (one that
;   binds to the IPv4 INADDR_ANY address, or the IPv6 unspecified
;   address, in6addr_any) to bind to the specific IP address that
;   is specified following the BIND keyword. This capability could
;   be used, for example, to allow z/OS UNIX telnet and telnet
;   3270 servers to both bind to TCP port 23.
;   The IP address that follows bind must be in IPv4 (dotted
;   decimal) or IPv6 (colon-hexadecimal) format and may be
;   any valid address for the host including VIPA and dynamic
;   VIPA addresses.
;
;   The special jobname of OMVS indicates that the PORT is reserved
;   for any application with the exception of those that use the Pascal
;   API.
```

```

;
; The special jobname of * indicates that the PORT is reserved
; for any application, including Pascal API socket applications.
;
; Jobname may be 1 - 8 characters including wildcards. The following
; wildcards are supported:
; - An asterisk (*) can be used in any position to indicate zero or
;   more unspecified characters.
; - A question mark (?) can be used in any position to indicate
;   a single unspecified character.
;
; The special jobname of RESERVED indicates that the PORT is
; blocked. It will not be available to any application.
;
; GUIDELINE: When IPSECURITY is enabled, UDP ports 500 and 4500
; should either be reserved for IKED (if it is in use) or should
; be marked RESERVED.
;
; TIP: The PORT statement can also be used to control application
; access to unreserved ports by configuring PORT entries where the
; port number is replaced by the keyword UNRSV.
;
PORT
  7 UDP MISC SERV      ; Miscellaneous Server - echo
  7 TCP MISC SERV      ; Miscellaneous Server - echo
  9 UDP MISC SERV      ; Miscellaneous Server - discard
  9 TCP MISC SERV      ; Miscellaneous Server - discard

; 1700 TCP PAGENT NOAUTOLOG ; Policy Agent pagentQosListener port
; 1701 TCP PAGENT NOAUTOLOG ; Policy Agent pagentQosCollector port
  3000 TCP CICS TCP    ; CICS Socket
  3389 TCP MSYSLDAP    ; LDAP Server for Msys
; 4159 TCP NSSD        ; CS NSS daemon
; 4500 UDP IKED        ; CS IKE daemon
; 16310 TCP PAGENT NOAUTOLOG ; Policy Agent server listener port
;
;
; PORTRANGE: Reserves a range of ports for specified jobnames.
;
; In a common INET (CINET) environment, the port range indicated by
; the INADDRANYPORT and INADDRANYCOUNT in your BPXPRMxx parmlib member
; should be reserved for OMVS.
;
; The special jobname of OMVS indicates that the PORTRANGE is reserved
; for ANY z/OS UNIX socket application.
;
; The special jobname of * indicates that the PORTRANGE is reserved
; for any socket application, including Pascal API socket
; applications.
;

```

```

; Jobname may be 1 - 8 characters including wildcards. The following
; wildcards are supported:
; - An asterisk (*) can be used in any position to indicate zero or
;   more unspecified characters.
; - A question mark (?) can be used in any position to indicate
;   a single unspecified character.
;
; The special jobname of RESERVED indicates that the PORTRANGE is
; blocked. It will not be available to any application.
;
; The SAF keyword is used to restrict access to the PORTRANGE to
; authorized users. See the use of SAF on the PORT statement above.
;
;
; PORTRANGE 4000 1000 TCP OMVS
; PORTRANGE 4000 1000 UDP OMVS
; PORTRANGE 2000 3000 TCP RESERVED
; PORTRANGE 5000 6000 TCP * SAF RANGE1
;

```

Figure 5. Sample TCP/IP start up proc

/etc/services and ETC.SERVICES port assignments

The z/OS UNIX file, /etc/services, contains the service names and port assignments of specific z/OS UNIX applications. The MVS data set ETC.SERVICES can also be used to contain the same information. The source for this example is shipped in SEZAINST(SERVICES) and copied to the *hlq*.ETC.SERVICES by the Installation Verification Procedure (IVP). The source is also installed in /usr/lpp/tcpip/samples/services for use in copying it to /etc/services. It is important that /etc/services and *hlq*.ETC.SERVICES be kept identical so that MVS and z/OS UNIX applications use the same port assignments. The shipped file contains the most current assignments.

Rules: The following syntax rules apply to the services information specification:

- An ETC.SERVICES data set must be fixed or fixed block with an LRECL between 56 and 256.
- The /etc/services z/OS UNIX file can have a maximum line length of 256.
- Each service is listed on a single line corresponding to the form:

```
ServiceName  PortNumber/ProtocolName  Aliases
```

ServiceName

Specifies an official Internet service name.

PortNumber

Specifies the socket port number used for the service.

ProtocolName

Specifies the transport protocol used for the service.

Aliases

Specifies a list of unofficial service names.

Items on a line are separated by spaces or tabs.

- A service name must start in the first position on a line.
- The maximum service name and alias name length is 32 characters.
- A maximum of 35 aliases is recognized.
- Service and alias names are case sensitive.
- Comments begin with a # or ; character and continue until the end of the line.

When services information is requested, the definitions are searched sequentially. The first entry matching a specified search request (either service name and protocol or port number and protocol) is returned.

For the search order used in locating /etc/services and ETC.SERVICES, see [z/OS Communications Server: IP Configuration Guide](#).

Tip: The following example was used for test configuration and is for illustration only.

Chapter 5. Resolver setup and TCPIP.DATA configuration statements

This topic contains the following information:

- [“Resolver setup statements” on page 295](#)
- [“Sample TCPIP.DATA data set \(TCPDATA\)” on page 339](#)

Resolver setup statements

The resolver address space can be customized with the following resolver setup statements summarized in [Table 7 on page 295](#).

See [z/OS Communications Server: IP Configuration Guide](#) for more information about resolvers.

Table 7. Summary of resolver setup statements

Statement	Description	See
CACHE/ NOCACHE	CACHE indicates that system-wide caching is enabled for the resolver. NOCACHE indicates that system-wide caching is not enabled for the resolver.	“CACHE NOCACHE statements” on page 299
CACHEREORDER/ NOCACHEREORDER	CACHEREORDER indicates that system-wide cache reordering is enabled for the resolver. NOCACHEREORDER indicates that system-wide cache reordering is disabled for the resolver.	“CACHEREORDER NOCACHEREORDER statements” on page 299
CACHESIZE	CACHESIZE specifies the maximum amount of storage that can be allocated by the resolver to manage cached records. Tip: CACHESIZE is ignored unless CACHE is also specified.	“CACHESIZE statement” on page 300

Table 7. Summary of resolver setup statements (continued)

Statement	Description	See
COMMONSEARCH/ NOCOMMONSEARCH	<p>COMMONSEARCH indicates that the search order for local host tables is the same regardless of whether the query is for IPv6 or IPv4 addresses. The search order is also the same regardless of whether the query is issued under the native MVS or the z/OS UNIX environment.</p> <p>NOCOMMONSEARCH indicates that the search order for local host tables is different for IPv4 and IPv6 queries. The search order is also different for queries issued under the native MVS environment, vs. queries issued under the z/OS UNIX environment.</p>	“COMMONSEARCH/NOCOMMONSEARCH statement” on page 301
DEFAULTIPNODES	<p>Specifies the name of either a z/OS UNIX file or MVS data set that contains the hard-coded IP addresses and host names to be used.</p> <p>Identifies the default search location for IPNODES local host file.</p>	“DEFAULTIPNODES statement” on page 301
DEFAULTTCPIPDATA	Specifies the name of either a z/OS UNIX file or MVS data set that contains the TCPIP.DATA statement that is used instead of TCPIP.TCPIP.DATA as the final location when searching for TCPIP.DATA.	“DEFAULTTCPIPDATA statement” on page 302
GLOBALIPNODES	<p>Specifies the name of either a z/OS UNIX file or MVS data set that contains the hard-coded IP addresses and host names to be used.</p> <p>Identifies the first search location for IPNODES local host file.</p>	“GLOBALIPNODES statement” on page 303
GLOBALTCPIPDATA	Specifies the name of either a z/OS UNIX file or MVS data set that contains the TCPIP.DATA statement that is used to set global MVS image-wide values for TCPIP.DATA.	“GLOBALTCPIPDATA statement” on page 304

Table 7. Summary of resolver setup statements (continued)

Statement	Description	See
MAXNEGTTL	Specifies the maximum amount of time the resolver can retain negative cache resource information obtained from a Domain Name System (DNS) name server as part of resource resolution.	“MAXNEGTTL statement” on page 306
MAXTTL	Specifies the maximum amount of time the resolver can use resource information obtained from a Domain Name System (DNS) server as part of resource resolution.	“MAXTTL statement” on page 306
UNRESPONSIVETHRESHOLD	Specify the threshold value for when a name server is declared to be unresponsive to resolver queries. Also specifies whether the resolver automatically stops sending DNS queries generated by an application to an unresponsive name server.	“UNRESPONSIVETHRESHOLD statement” on page 307
; or #	Indicates a comment.	“; and # statements” on page 309

Resolver setup statement information and syntax conventions

This topic explains each of the resolver setup statements in detail.

If resolver setup statements are contained in a data set, the data set can have the following characteristics:

- Sequential (PS) or partitioned (PO) organization
- Fixed (F) or fixed block (FB) format
- Recommended logical record length (LRECL) in the range 80 - 256
- Any valid block size

Restriction: If resolver setup statements are contained in a z/OS UNIX file, the file can have a maximum line length of 256.

Observe the following syntax conventions for resolver setup statements:

- A blank indicates the end of a statement's values. Anything following the blank on the same line is treated as a comment.
- Static system symbols can be used in resolver setup file statements.
- If a valid statement has any parameter error, a warning message is displayed on the operator console and in the JES job log.
 - If the statement was found during resolver address space initialization, the statement is ignored. Processing of the setup statements continues.
 - If the statement was found while processing a MODIFY RESOLVER,REFRESH,SETUP command, processing of the setup statements ends, the MODIFY fails, and no refresh takes place.
- If an invalid statement is found, a warning message is displayed on the operator's console and in the JES job log.

- If the invalid statement was found during resolver address space initialization, the statement is ignored. Processing of the setup statements continues.
- If the invalid statement was found while processing a MODIFY RESOLVER,REFRESH,SETUP command, processing of the setup statements ends, the MODIFY fails, and no refresh takes place.
- When setup file processing is complete, the resolver attempts to open the MVS data set or z/OS UNIX file name specified as the parameter on the last valid instance of the GLOBALIPNODES, DEFAULTIPNODES, GLOBALTCPIPDATA, and DEFAULTTCPIPDATA setup statements. If the parameter value was incorrect or the specified z/OS UNIX or MVS data set does not exist, a warning message is displayed on the operator console and in the JES job log.
 - If the error occurred during resolver address space initialization, processing continues. The resolver assumes the default setting for the setup statement, which in this case is no file was specified.
 - If the error occurred while processing a MODIFY RESOLVER,REFRESH,SETUP command, processing of the setup statements ends, the MODIFY fails, and no refresh takes place.
- When the setup file processing successfully completes, each resolver statement's value is displayed on the operator console and in the JES job log. If a resolver statement can specify an MVS data set or z/OS UNIX file and none was specified, the word NONE is displayed as the statement's value on the operator console and in the JES job log.
- The resolver processes an MVS data set or z/OS UNIX file specified on the GLOBALTCPIPDATA resolver setup statement differently than data sets or files that are specified on other resolver setup statements:
 - During the initialization of the resolver address space and while processing the MODIFY,REFRESH command, the resolver reads the contents of the MVS data set or the z/OS UNIX file that is specified on the GLOBALTCPIPDATA resolver setup statement. The resolver saves the information for resolver NMI purposes. See [Resolver NMI \(EZBREIFR\)](#) in [z/OS Communications Server: IP Programmer's Guide and Reference](#) for details.
 - For all other data set or file specifications, the contents of an MVS data set or z/OS UNIX file that is specified by a resolver setup statement are not validated during the initialization of the resolver address space or while the MODIFY,REFRESH command is processing. The contents are validated when the first usage of resolver services is requested by an address space.
- If the resolver address space abnormally terminates, an eventual action message is issued which indicates the failure. Use the START operator command to restart the Resolver address space.
- Resolver initialization deletes any resolver-related eventual action messages.
- If an allocation error occurs when trying to access a resolver statement's MVS data set or z/OS UNIX file, an eventual action message is issued to the operator console. Only one eventual action message per MVS data set or z/OS UNIX file is issued regardless of the number of times the file is accessed. After a successful reference to the file has occurred, the message is removed from the operator console.
 - If the allocation error occurs during resolver address space initialization, processing continues.
 - If the allocation error occurs while resolver is processing a MODIFY RESOLVER,REFRESH command, processing of the setup statements ends and the MODIFY command fails. No refresh takes place.
 - If the allocation error occurs during a resolver API call, processing of the resolver API continues. The resolver takes default values, if appropriate, for any statements that could have appeared in the data set or file.
- If no errors are detected during resolver address space initialization, the resolver issues message EZZ9291I at the completion of initialization processing. If an error is detected, the resolver issues message EZD2038I. You can create automation to look for message EZD2038I and to alert you about errors in your resolver setup file that might cause the resolver to behave differently than intended.

To determine the current setting of the resolver setup statements, use the MODIFY RESOLVER,DISPLAY operator console command. See [z/OS Communications Server: IP System Administrator's Commands](#) for MODIFY command.

For more information about resolvers, see [z/OS Communications Server: IP Configuration Guide](#)

CACHE NOCACHE statements

Restriction: Resolver caching is not used for applications running in IBM z/OS Container Platform environments. This statement is ignored.

Use the CACHE statement to enable system-wide caching for the resolver. Use the NOCACHE statement to disable system-wide caching.

System-wide caching saves resource information obtained from name servers during processing of application queries, which permits subsequent queries for the same resource to be satisfied without contacting the name server for the information. The resolver caches both positive and negative resource information. For more information about the resolver caching function, see [z/OS Communications Server: IP Configuration Guide](#).

The default value is CACHE.

Syntax

Parameters

This statement has no parameters.

CACHEREORDER NOCACHEREORDER statements

Use the CACHEREORDER statement to enable system-wide cache reordering for the resolver. Use the NOCACHEREORDER statement to disable system-wide cache reordering.

Tip: If you specify the NOCACHE statement, the CACHEREORDER and NOCACHEREORDER statements are ignored.

When system-wide cache reordering is enabled, the resolver reorders the list of cached IP addresses after retrieving the cached information in response to a host name resolution request. The list is reordered in a round-robin manner. See [Cache reordering in z/OS Communications Server: IP Configuration Guide](#) for more information.

The default value is NOCACHEREORDER.

Syntax

Parameters

This statement has no parameters.

Usage notes

- You can change the value of CACHEREORDER or NOCACHEREORDER dynamically by using the **MODIFY RESOLVER, REFRESH, SETUP=resolver_setup_filename** command. Changing the value of CACHEREORDER or NOCACHEREORDER dynamically has no affect on existing resolver API requests, but the new value applies to new resolver API requests that are processed after the MODIFY command completes.

- Resolver address sorting algorithms, such as the TCPIP.DATA SORTLIST statement, can further modify the list of cached IP addresses. For more information, see [Cache reordering and sorting in z/OS Communications Server: IP Configuration Guide](#).

CACHESIZE statement

Use the CACHESIZE statement to specify the maximum amount of storage that can be allocated by the resolver to manage cached records.

Tip: When the CACHESIZE statement is specified with the NOCACHE statement, the CACHESIZE operand is ignored.

Syntax

Parameters

cachesize M

Specifies the maximum amount of 64-bit private virtual storage that the resolver can use to maintain cache information. This limit should be expressed as a number followed by an M (which represents 1 048 576 bytes). The *cachesize* value must be in the range 1M - 999M. The default is 200M.

Examples

Use the CACHESIZE statement to set 10 M as the maximum cache size value:

```
CACHESIZE (10M)
```

Usage notes

- For planning purposes, 1 megabyte of storage can contain between 400 and 450 cache entries. The actual values can vary depending on the amount of storage needed to hold cache infrastructure control blocks used to represent the entries and the name servers providing the information.
- The resolver acquires cache storage incrementally as needed, up to the maximum specified by the CACHESIZE operand. Because storage is acquired incrementally, there is no penalty for specifying a CACHESIZE value significantly greater than the expected maximum amount of storage required. This avoids storage constraint processing during spikes in the amount of information being cached. Consider specifying a value at least fifty percent larger than the amount of storage you actually expect to be used for cache entries.
- You can increment the value of *cachesize M* dynamically by issuing the MODIFY RESOLVER,REFRESH,SETUP=*resolver_setup_filename* command. You cannot decrease the value of *cachesize M* dynamically. If you attempt to lower the value of CACHESIZE dynamically, the MODIFY command fails and message EZZ9306I is issued. To decrease the value of *cachesize M*, you must stop and restart the resolver. Alternatively, update the resolver setup file to indicate NOCACHE and issue a MODIFY RESOLVER,REFRESH,SETUP=*resolver_setup_filename* command to first stop resolver caching, and then issue a second MODIFY RESOLVER,REFRESH,SETUP=*resolver_setup_filename* command that both restarts resolver caching and decrease the value of *cachesize M*.

COMMONSEARCH/NOCOMMONSEARCH statement

Use the COMMONSEARCH statement to indicate that the search order for local host table is the same regardless of whether it is for an IPv6 or an IPv4 query, or whether the query is issued in the native MVS or z/OS UNIX environment. The default is NOCOMMONSEARCH.

Restrictions:

- You must code the COMMONSEARCH statement if you use IPNODES for the local hosts file. For more information, see [search orders used in the z/OS UNIX environment](#) and [Search orders used in the native MVS environment](#) in [z/OS Communications Server: IP Configuration Guide](#).
- This statement is ignored for applications running in IBM z/OS Container Platform environments. The resolver configuration is always obtained from the z/OS UNIX files '/etc/resolv.conf' and '/etc/nsswitch.conf' in the container's filesystem namespace. For more information, see [search orders used in the z/OS UNIX environment](#) in [z/OS Communications Server: IP Configuration Guide](#).

Syntax

Parameters

This statement has no parameters.

Examples

To code COMMONSEARCH:

```
COMMONSEARCH
```

DEFAULTIPNODES statement

Use the DEFAULTIPNODES statement to specify the name of either a z/OS UNIX file or MVS data set that contains the hard-coded IP addresses and host names to be used.

Restriction: The specified file or data set can contain IPv4 and IPv6 addresses, but cannot contain IPv4-mapped addresses.

Syntax

Parameters

'fully qualified MVS dataset name'

The complete name of the MVS data set containing the IP addresses and host names. The data set name is not case sensitive.

Requirement: The beginning and ending quotation marks (' ') are required.

/file system absolute pathname

The complete name of the z/OS UNIX file containing the IP addresses and host names. The z/OS UNIX path name is case sensitive.

Requirement: The beginning slash (/) is required.

Restriction: The /file system absolute path name can be a maximum of 255 characters.

Examples

To specify the data set named TCPIP.ETC.IPNODES, use the following code:

```
DEFAULTIPNODES('TCPIP.ETC.IPNODES')
```

To specify z/OS UNIX file ipnodes in directory etc as containing IP addresses and host names, use the following code:

```
DEFAULTIPNODES(/etc/ipnodes)
```

Note: Because it is a z/OS UNIX file, the name is case sensitive.

Usage notes

- For a z/OS UNIX file, the file can reside in any directory. The maximum line length supported is 256 characters. If the line is greater than 256 characters, it is truncated to 256 characters and processed, and a trace resolver warning message is issued.
- For an MVS data set, the following conditions are required:
 - Sequential (PS) organization or PDS
 - RECFM=F or RECFM=FB
 - A logical record length (LRECL) in the range 80 - 256
- This specified file or data set can include IPv4 and IPv6 addresses, but cannot include IPv4-mapped addresses. Each host name can be up to 128 characters in length, and each host name can have up to 35 IPv4 addresses and 35 IPv6 addresses. Each node in the host name (without dots) can be up to 63 characters in length. For example, if host name is testname.testdomain, *testname* and *testdomain* can be up to 63 characters in length.

DEFAULTTCPIPDATA statement

Use the DEFAULTTCPIPDATA statement to specify the name of either a z/OS UNIX file or MVS data set that contains the TCPIP.DATA statements. This name is used, instead of TCPIP.TCPIP.DATA, as the final location when searching for TCPIP.DATA statements.

Syntax

Parameters

'fully qualified MVS dataset name'

The complete name of the MVS data set containing the TCPIP.DATA statements.

Requirement: The beginning and ending quotation marks (' ') are required.

/file system absolute pathname

The complete name of the z/OS UNIX file containing the TCPIP.DATA statements.

Requirement: The beginning slash (/) is required.

Restriction: The /file system absolute path name can be a maximum of 255 characters.

Examples

The following example specifies member RESLVCF in partitioned data set TCPIP.TCPPARMS as containing TCPIP.DATA statements.

```
DEFAULTTCPIPDATA('TCPIP.TCPPARMS(RESLVCF)')
```

The following example specifies z/OS UNIX file DefaultTcpi.data in directory etc as containing TCPIP.DATA statements.

Note: Because it is a z/OS UNIX file, the name is case sensitive.

```
DEFAULTTCPIPDATA(/etc/DefaultTcpi.data)
```

Usage notes

- For a z/OS UNIX file, the file can reside in any directory. The maximum line length supported is 256 characters. If the line is greater than 256 characters, it is truncated to 256 characters and processed, and a trace resolver warning message is issued.
- The z/OS UNIX path name is case sensitive.
- For an MVS data set, the following conditions are required:
 - Sequential (PS) or Partitioned (PO) organization
 - RECFM=F or RECFM=FB
 - Recommended logic record length (LRECL) in the range 80 - 256
- The MVS data set name is not case sensitive.

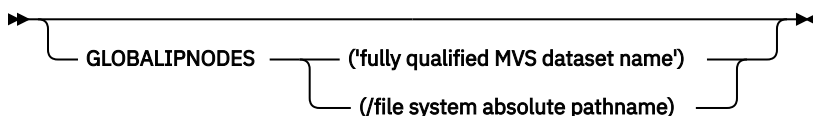

GLOBALIPNODES statement

Use the GLOBALIPNODES statement to specify the name of either a z/OS UNIX file or MVS data set that contains the hard-coded IP addresses and host names to be used.

Restrictions:

- The specified file or data set can include IPv4 and IPv6 addresses, but cannot include IPv4-mapped addresses.
- This statement is ignored for applications running in IBM z/OS Container Platform environments. The resolver configuration is always obtained from the z/OS UNIX file '/etc/resolv.conf' in the container's filesystem namespace. For more information, see [search orders used in the z/OS UNIX environment in z/OS Communications Server: IP Configuration Guide](#).

Syntax

Parameters

'fully qualified MVS dataset name'

The complete name of the MVS data set containing the IP addresses and host names. The data set name is not case sensitive.

Requirement: The beginning and ending quotation marks (' ') are required.

/file system absolute pathname

The complete name of the file system containing the IP addresses and host names. The z/OS UNIX path name is case sensitive.

Requirement: The beginning slash (/) is required.

Restriction: The /file system absolute path name can be a maximum of 255 characters.

Examples

To specify the data set named TCPIP.ETC.IPNODES, use the following code:

```
GLOBALIPNODES('TCPIP.ETC.IPNODES')
```

To specify z/OS UNIX file **ipnodes** in directory etc as containing IP addresses and host names, use the following code:

```
GLOBALIPNODES(/etc/ipnodes)
```

Note: Because it is an z/OS UNIX file, the name is case sensitive.

Usage notes

- For a z/OS UNIX file, the file can reside in any directory. The maximum line length supported is 256 characters. If the line is greater than 256 characters, it is truncated to 256 characters and processed, and a trace resolver warning message is issued.
- For an MVS data set, the following conditions are required:
 - Sequential (PS) organization or PDS
 - RECFM=F or RECFM=FB
 - Recommended logic record length (LRECL) in the range 80 - 256
- This specified file or data set can contain IPv4 and IPv6 addresses, but cannot contain IPv4-mapped addresses. Each host name can be up to 128 characters in length, and each host name can have up to 35 IPv4 addresses and 35 IPv6 addresses. Each node in the host name (without dots) can be up to 63 characters in length. For example, if host name is testname.testdomain, *testname* and *testdomain* can be to 63 characters in length.

GLOBALTCPIPDATA statement

Use the GLOBALTCPIPDATA statement to specify the name of either a z/OS UNIX file or MVS data set that contains the TCPIP.DATA statements that are used to set global MVS image-wide values for TCPIP.DATA.

Restriction: This statement is ignored for applications running in IBM z/OS Container Platform environments. The resolver configuration is always obtained from the z/OS UNIX files '/etc/resolv.conf' and '/etc/nsswitch.conf' in the container's filesystem namespace. For more information, see [search orders used in the z/OS UNIX environment](#) in [z/OS Communications Server: IP Configuration Guide](#).

If GLOBALTCPIPDATA is not specified, the appropriate environment's (Native MVS or z/OS UNIX) search order is used to locate TCPIP.DATA.

If GLOBALTCPIPDATA is specified, any TCPIP.DATA statements contained in the specified file or data set take precedence over any TCPIP.DATA statements found using the appropriate environment's (native MVS or z/OS UNIX) search order.

The following resolver TCPIP.DATA statements can be specified only in the file or data set specified by GLOBALTCPIPDATA. If these resolver statements are found in any of the other search locations for TCPIP.DATA, they are ignored. If these resolver statements are not found in the file or data set specified by GLOBALTCPIPDATA, their default value is used.

- DomainOrigin/Domain
- NSInterAddr/NameServer
- NSPortAddr
- ResolverTimeOut
- ResolverUDPRetries

- ResolveVia
- Search
- SortList

Syntax

Parameters

'fully qualified MVS dataset name'

The complete name of the MVS data set containing the TCPIP.DATA statements.

Requirement: The beginning and ending quotes (' ') are required.

/file system absolute pathname

The complete name of the z/OS UNIX file containing the TCPIP.DATA statements.

Requirement: The beginning slash (/) is required.

Restriction: The /file system absolute path name can be a maximum of 255 characters.

Examples

The following example specifies member GLOBAL in partitioned data set TCPIP.TCPPARMS as containing TCPIP.DATA statements.

```
GLOBALTCPIPDATA('TCPIP.TCPPARMS(GLOBAL)')
```

The following example specifies z/OS UNIX file Global.Tcpip.data in directory etc as containing TCPIP.DATA statements.

Note: Because it is a z/OS UNIX file the name is case sensitive.

```
GLOBALTCPIPDATA(/etc/Global.Tcpip.data)
```

Usage notes

- For a z/OS UNIX file, the file can reside in any directory. The maximum line length supported is 256 characters. If the line is greater than 256 characters, it is truncated to 256 characters and processed, and a trace resolver warning message is issued.
- The z/OS UNIX path name is case sensitive.
- For an MVS data set, the following conditions are required:
 - Sequential (PS) or Partitioned (PO) organization
 - RECFM=F or RECFM=FB
 - Recommended logic record length (LRECL) in the range 80 - 256
- The MVS data set name is not case sensitive.
- You must code the GLOBALTCPIPDATA statement if you specify the AUTOQUIESCE operand on the UNRESPONSIVETHRESHOLD statement. If you cannot ensure that all DNS IP addresses are accessible from all of your TCPIP stacks, you should not use a global TCPIP.DATA file and you should not code AUTOQUIESCE on the UNRESPONSIVETHRESHOLD setup statement in your resolver setup file. See [“UNRESPONSIVETHRESHOLD statement” on page 307](#) for more information.

MAXNEGTTT statement

Use the MAXNEGTTT statement to specify the maximum amount of time the resolver can cache negative responses from a Domain Name System (DNS) name server as part of resource resolution.

Tip: When MAXNEGTTT is specified with NOCACHE, the value is ignored.

Syntax

Parameters

time-to-live

Specifies the maximum amount of time, in seconds, that the resolver is permitted to use cached information for a negative response about a resource obtained from a DNS name server. The *time-to-live* value must be in the range 0 - 2 147 483 647. The default is the value for MAXTTT, if it was specified, or else 2 147 483 647. The value 2 147 483 647 is the largest value that can be specified for the *time-to-live* value for a resource at a DNS name server.

Specifying, or defaulting to, a value of 2 147 483 647 means that the resolver uses the *time-to-live* value received from the DNS name server to determine how long the negative resource information can be used.

Specifying a value of 0 indicates that the resolver should not cache any negative responses from DNS name servers.

Examples

The following code is an example of coding 10 seconds as the maximum *time-to-live* value for negative cache entries by using the MAXNEGTTT statement:

```
MAXNEGTTT (10)
```

Usage notes

- You can change the value for MAXNEGTTT dynamically using the MODIFY RESOLVER, REFRESH, SETUP=*resolver_setup_filename* command.
 - Changing the value of MAXNEGTTT dynamically has no effect on existing records in the resolver cache, but the new value is used for cache records created after the MODIFY command completes.
 - Changing the value of MAXNEGTTT dynamically to 0 prevents additional negative cache entries from being created, but does not delete existing records from the resolver cache.
- The value for MAXNEGTTT only applies to negative cache records. Use the MAXTTT statement to define the maximum amount of time to be used for cache records that represent successful resolution attempts. See [MAXTTT statement](#) for additional information.
- If the time-to-live value that is received from the DNS name server for a given resource is lower than the MAXNEGTTT value, the negative cache entry times out based on the DNS name server TTL value.
- If the time-to-live value that is received from the DNS name server for a given resource is higher than the MAXNEGTTT value, the negative cache entry times out based on the MAXNEGTTT value.

MAXTTT statement

Use the MAXTTL statement to specify the maximum amount of time the resolver can use resource information obtained from a Domain Name System (DNS) name server as part of resource resolution.

Tip: When MAXTTL is specified with NOCACHE, the value is ignored.

Syntax

Parameters

time-to-live

Specifies the maximum amount of time, in seconds, that the resolver is permitted to use cached information about a resource obtained from a DNS name server. The *time-to-live* value must be in the range 1 - 2 147 483 647. The default is 2 147 483 647, which is the largest value that can be specified for the *time-to-live* value for a resource at a DNS name server. Specifying, or defaulting to, a value of 2 147 483 647 means that the resolver uses the *time-to-live* value received from the DNS name server to determine how long the resource information can be used.

Examples

The following code is an example of coding 10 minutes (or 600 seconds) as the maximum *time-to-live* value by using the MAXTTL statement:

```
MAXTTL (600)
```

Usage notes

- You can change the value for MAXTTL dynamically using the MODIFY RESOLVER,REFRESH,SETUP=*resolver_setup_filename* command. Changing the value of MAXTTL dynamically has no affect on existing records in the resolver cache, but the new value is used for cache records created after the MODIFY command completes.
- The value for MAXTTL always applies to cache records that represent successful resolution attempts. The value for MAXTTL may also be used for negative cache records, unless the MAXNEGTTT statement is also specified. If a MAXNEGTTT is specified, that value is used as the maximum amount of time that negative cache entries are retained. See [“MAXNEGTTT statement” on page 306](#) for additional information.
- If the time-to-live value that is received from the DNS name server for a given resource is lower than the MAXTTL value, the cached entry times out based on the DNS name server TTL value.
- If the time-to-live value that is received from the DNS name server for a given resource is higher than the MAXTTL value, the cached entry times out based on the MAXTTL value

UNRESPONSIVETHRESHOLD statement

Use the UNRESPONSIVETHRESHOLD statement to specify the threshold value for when the resolver name server monitoring function declares a DNS name server to be unresponsive to resolver queries, and to specify whether the resolver should automatically stop using unresponsive name servers for Domain Name System (DNS) queries generated by an application. For detailed information about the name server monitoring function and about selecting an appropriate value for UNRESPONSIVETHRESHOLD, see the [information about monitoring the responsiveness of Domain Name System name servers in z/OS Communications Server: IP Configuration Guide](#).

Syntax

Parameters

percentage_of_queries

The threshold value for determining when the resolver declares a DNS name server to be unresponsive. The threshold represents a percentage of failures within a specific time interval. The duration of the time interval depends on the setting of the AUTOQUIESCE operand:

- If you do not specify the AUTOQUIESCE operand, the resolver monitors name server responsiveness using sliding 5-minute intervals.
- If you specify the AUTOQUIESCE operand, the resolver monitors name server responsiveness using 30-second intervals.

Valid values for *percentage_of_queries* are in the range 0-100.

The value 0 indicates that the resolver should not monitor name server responsiveness.

The default percentage depends on the setting of the AUTOQUIESCE operand:

- If you do not specify the AUTOQUIESCE operand, the default percentage value is 25% of resolver queries.
- If you specify the AUTOQUIESCE operand, there is no default percentage. You must specify a percentage value when specifying the AUTOQUIESCE operand.

AUTOQUIESCE

Indicates what actions the resolver takes when it identifies an unresponsive name server.

- If you do not specify the AUTOQUIESCE operand and a name server fails to respond to a percentage of resolver queries that is equal to or greater than the specified threshold level, the resolver displays message EZZ9308E to the operator console to indicate that the name server has been unresponsive for this latest 5-minute interval. The resolver continues to forward DNS queries generated by an application to the name server whether it is responsive or not. The name server is considered to be unresponsive until the percentage of queries that the name server does not respond to is less than the specified threshold, or until monitoring is disabled.
- If you specify the AUTOQUIESCE operand and a name server fails to respond to a percentage of resolver queries that is equal to or greater than the specified threshold level, the resolver displays message EZZ9311E to the operator console to indicate that the name server has been unresponsive for this latest 30-second interval. The resolver stops sending DNS queries generated by an application to the name server while the name server is unresponsive. While a name server is unresponsive, the resolver periodically sends DNS polling queries to the name server. The name server is considered to be unresponsive until the percentage of DNS polling queries that the name server does not respond to is less than the specified threshold, or until the monitoring is disabled. In most cases, a minimum of 10 DNS polling queries must be attempted before the resolver considers a name server to be responsive.

Result: If all name servers specified in the global TCPIP.DATA file are unresponsive, the resolver sends DNS queries generated by an application to those name servers, rather than failing the DNS query immediately.

The AUTOQUIESCE operand is used only when the *percentage_of_queries* value is greater than 0.

If you specify the AUTOQUIESCE operand, you must also code the GLOBALTCPIPDATA statement. If you do not code the GLOBALTCPIPDATA statement, the resolver issues message EZD2036I and ignores the AUTOQUIESCE operand. If you cannot ensure that all DNS IP addresses are accessible

from all of your TCPIP stacks, you should not use a global TCPIP.DATA file and you should not code AUTOQUIESCE on the UNRESPONSIVETHRESHOLD setup statement in your resolver setup file. See [“GLOBALTCPIPDATA statement” on page 304](#) for details on coding the GLOBALTCPIPDATA statement.

The default setting is that AUTOQUIESCE is not specified.

Steps for modifying

You can refresh this statement using the MODIFY command. To modify the threshold value, the setting of the AUTOQUIESCE operand, or both, perform the following steps:

1. If you do not have a resolver setup file, create one.
2. Specify the percentage value and the required setting for the AUTOQUIESCE operand on the UNRESPONSIVETHRESHOLD statement in the resolver setup file. The following guidelines apply when you modify the value for the UNRESPONSIVETHRESHOLD statement:
 - If you change the value to 0, the function is disabled, all accumulated statistics are deleted, and any unresponsive name server notification messages are cleared from the operator console.
 - If you change the value to a nonzero value but you do not change the value of the AUTOQUIESCE operand, the new threshold percentage will be used when the next time interval ends.
 - If you do not specify the AUTOQUIESCE operand and the resolver was already monitoring name server responsiveness, existing statistics that were accumulated during the 1-minute interval are not affected and current EZZ9308E unresponsive name server messages remain on the operator console.
 - If you specify the AUTOQUIESCE operand and the resolver was already monitoring name server responsiveness, existing statistics that were accumulated during the 30-second interval are not affected and current EZZ9311E unresponsive name server messages remain on the operator console.
 - If you change the value of the AUTOQUIESCE operand, all accumulated statistics are deleted and any unresponsive name server messages (EZZ9308E or EZZ9311E) are cleared from the operator console. The resolver uses the specified threshold percentage when the next time interval (5-minutes or 30-seconds) ends.
3. Issue the MODIFY RESOLVER,REFRESH,SETUP=*setup_filename* command to cause the resolver to use the new threshold value, the AUTOQUIESCE operand setting, or both.

For more information about parameters used with the [MODIFY command](#), see [z/OS Communications Server: IP System Administrator's Commands](#).

Examples

To specify a 50% threshold value and cause the resolver to continue sending DNS queries generated by an application to an unresponsive name server, specify the following value:

```
UNRESPONSIVETHRESHOLD(50)
```

To specify a 100% threshold value and cause the resolver to stop sending DNS queries generated by an application to an unresponsive name server, specify the following values:

```
UNRESPONSIVETHRESHOLD(100,AUTOQUIESCE)
```

; and # statements

Use ; or # to indicate comments. Any data after the ; or # character is treated as a comment.

Configuration statements in TCPIP.DATA

The TCPIP.DATA configuration statements are summarized in [Table 8 on page 310](#).

Table 8. Summary of TCPIP.DATA configuration statements

Statement	Description	See
ALWAYSWTO	Issue WTO messages for servers.	“ALWAYSWTO statement” on page 314
DATASETPREFIX	Set the high-level qualifier for dynamic allocation of data sets.	“DATASETPREFIX statement” on page 315
DOMAINORIGIN or DOMAIN (see note)	Specify the domain origin that is appended to the host name to form the fully qualified domain name of a host.	“DOMAINORIGIN statement” on page 316
HOSTNAME	Specify the TCP host name of the z/OS communication server.	“HOSTNAME statement” on page 317
LOADDBCSTABLES	Indicate to FTP which DBCS translation tables can be loaded.	“LOADDBCSTABLES statement” on page 318
LOOKUP	Specify the order in which the DNS and the local host file are to be used for name resolution.	“LOOKUP statement” on page 319
MESSAGECASE	Specify case translation for the FTP server and osnmpd.	“MESSAGECASE statement” on page 320
NOCACHE	Specify that the resolver should not use the system-wide cache for any queries associated with applications that use this TCPIP.DATA file. The cache is bypassed for any queries from a DNS server and results obtained from a DNS server are not updated in the cache.	“NOCACHE statement” on page 321
NOCACHEREORDER	Specify that the resolver should not reorder the list of IP addresses that are provided in response to a resolution request for the associated host name.	“NOCACHEREORDER statement” on page 322
NSINTERADDR or NAMESERVER	Define the IP address of a name server. The IP address can be either IPv4 or IPv6.	“NSINTERADDR statement” on page 323
Note: A synonym that provides common statements regardless of whether the statements are defined in an MVS data set or z/OS UNIX file.		
NSPORTADDR	Specify the name server port number.	“NSPORTADDR statement” on page 325
OPTIONS	Specify if resolver debug messages should be issued and the number of periods (.) that need to be contained in a domain name for it to be considered a fully qualified domain name.	“OPTIONS statement” on page 326

Table 8. Summary of TCPIP.DATA configuration statements (continued)

Statement	Description	See
RESOLVERTIMEOUT	Specify how long the resolver waits for a response while trying to communicate with the name server.	“RESOLVERTIMEOUT statement” on page 328
RESOLVERUDPRETRIES	Specify how many times the resolver tries to connect to the name server when using UDP datagrams.	“RESOLVERUDPRETRIES statement” on page 329
RESOLVEVIA	Specify the protocol used by the resolver to communicate with the name server.	“RESOLVEVIA statement” on page 331
SEARCH	Specify the list of domain names that are appended, in the order listed, to the host name to form the fully qualified domain name of a host.	“SEARCH statement” on page 332
SOCKDEBUG	Turn on tracing of TCP/IP socket library calls.	“SOCKDEBUG statement” on page 333
SOCKNOTESTSTOR	Stop checking of TCP/IP socket calls for storage access errors on the parameters to the call.	“SOCKNOTESTSTOR statement” on page 333
SOCKTESTSTOR	Enable checking of TCP/IP socket calls for storage access errors on the parameters to the call.	“SOCKTESTSTOR statement” on page 334
SORTLIST	Specify the ordered list of network numbers (subnets or networks) for the resolver to prefer if it receives multiple addresses as the result of a name query.	“SORTLIST statement” on page 334
TCPIPJOBNAME or TCPIPUSERID (see note)	Specify the member name of the cataloged procedure used to start the TCPIP address space.	“TCPIPJOBNAME statement” on page 336
TRACE RESOLVER	Trace all queries to and responses from the name server.	“TRACE RESOLVER statement” on page 337
TRACE SOCKET	Trace TCP/IP C socket library calls.	“TRACE SOCKET statement” on page 338
; or #	Use either character to indicate a comment.	“; and # statements” on page 309

Rule: If any TCPIP.DATA statement is in the GLOBALTCIPDATA file, it is always used, regardless of what is found in any subsequent TCPIP.DATA statements from the search list.

system_name considerations

The *system_name* parameter on the statements is derived from the MVS system name. If you have configured VMCF and TNF as non-restartable subsystems, the system name is specified in the IEFSSNxx member of PARMLIB. If you have configured VMCF and TNF as restartable subsystems, the system name is obtained from the value of the P= parameter of the EZAZSSI started procedure. See "Step 3: Configure VMCF and TNF" in [z/OS Communications Server: IP Configuration Guide](#) for information about starting VMCF.

sysname above is the name specified by the IEASYSxx parmlib member's SYSNAME= parameter value. For more information about the SYS1.PARMLIB member definitions, see [z/OS MVS Initialization and Tuning Guide](#).

For more information about using the *system_name* parameter, see the TCPIP.DATA statements configuration information in [z/OS Communications Server: IP Configuration Guide](#)

Dynamically changing TCPIP.DATA statements

You can use the MODIFY RESOLVER,REFRESH command to change some of the TCPIP.DATA statements being used by a long-running TCP/IP application (for example, a server application). To do this, follow either of the following procedures.

Restrictions: You cannot change the TCPIP.DATA statement values for the following subset of TCP/IP provided applications:

- DNS utility z/OS UNIX commands (nslookup, onslookup and dig)
- Any application program that uses the Language Environment C/C++ res_ API facilities and changed the updated TCPIP.DATA statement

Table 9 on page 312 lists the TCPIP.DATA statements and whether each statement can be dynamically changed (refreshed). For more information about MODIFY command, see [z/OS Communications Server: IP System Administrator's Commands](#) and to [z/OS Communications Server: IP Configuration Guide](#) for information about [configuring resolvers](#).

Table 9. Refreshable TCPIP.DATA	
TCPIP.DATA statement	Refreshable
ALWAYSWHO	No
DATASETPREFIX	No
DOMAINORIGIN or DOMAIN	Yes
HOSTNAME	No
LOADDBCSTABLES	No
LOOKUP	Yes
MESSAGECASE	No
NOCACHE	Yes
NOCACHEREORDER	Yes
NSINTERADDR or NAMESERVER	Yes
NSPORTADDR	Yes
RESOLVEVIA	Yes
RESOLVERTIMEOUT	Yes
RESOLVERUDPRETRIES	Yes
SEARCH	Yes
SOCKDEBUG	No
SOCKNOTESTSTOR	No
SOCKTESTSTOR	No
SORTLIST	Yes
TCPIPJOBNAME or TCPIPUSERID	No
TRACE RESOLVER	Yes
TRACE SOCKET	No

<i>Table 9. Refreshable TCPIP.DATA (continued)</i>	
TCPIP.DATA statement	Refreshable
OPTIONS DEBUG	Yes
OPTIONS NDOTS	Yes
; or # (COMMENT)	NA

Steps for dynamically changing TCPIP.DATA statements without using GLOBALTCPIPDATA:

This topic describes the steps of dynamically changing the TCPIP.DATA statements, but not using GLOBALTCPIPDATA.

Procedure

Perform the following steps to dynamically change TCPIP.DATA statements without using GLOBALTCPIPDATA.

1. Change the MVS data set or z/OS UNIX file currently being used for TCPIP.DATA statements to the new values.
2. To use the changed values, issue the MODIFY RESOLVER,REFRESH command. When application programs that are configured to use the TCPIP.DATA file make their next resolver socket call (for example, gethostbyaddr or gethostbyname), the new values are used.

Step for dynamically changing TCPIP.DATA statements using GLOBALTCPIPDATA:

This topic describes the steps of dynamically changing the TCPIP.DATA statement by using GLOBALTCPIPDATA.

Procedure

Use the preceding procedure to change the GLOBALTCPIPDATA file.

Steps for creating a new GLOBALTCPIPDATA data set or file

Alternatively, you could create a new GLOBALTCPIPDATA data set or file.

Procedure

Perform the following steps to create a new GLOBALTCPIPDATA data set or file.

1. Create a new resolver setup file in which the GLOBALTCPIPDATA statement points to the new TCPIP.DATA file.
2. To use the changed values, issue the MODIFY RESOLVER,REFRESH,SETUP= command specifying the new resolver setup name. When application programs make their next resolver socket call (for example, gethostbyaddr or gethostbyname), the new values are used.

Determining which TCPIP.DATA statements are being used

Use the Trace Resolver facility to determine which TCPIP.DATA values the resolver is using and where they were read from. See [z/OS Communications Server: IP Diagnosis Guide](#) for information about how to dynamically start the [trace](#). After the trace is active, issue use the Netstat HOME/-h command to display the values. Issuing a ping of a host name from TSO and from the z/OS UNIX shell also shows activity to any DNSs that might be configured.

Syntax conventions for TCPIP.DATA configuration statements

Observe the following syntax conventions for TCPIP.DATA statements:

- A data set containing TCPIP.DATA statements must be fixed or fixed block with a suggested logic record length (LRECL) in the range 80 - 256. The data set should not contain line numbers, because the line numbers are treated as parameter values for statements that allow multiple parameters.
- A z/OS UNIX file containing TCPIP.DATA statements can have a maximum line length of 256.
- Only one statement is allowed on each line.
- A statement can start in any position on a line.
- Statements are not case sensitive.
- Statements can be preceded by an optional *system_name*.
- Static system symbols can be used in statements.
- A blank line is treated as a comment.
- For statements with a single parameter value or no parameter value, a blank after the value ends the statement. Anything on the line following the blank is treated as a comment.
- For statements accepting multiple parameter values (for example, SEARCH, LOOKUP, NSINTERADDR/NAMESERVER, SORTLIST, OPTIONS, and LOADDBCSTABLES), at least one blank followed by either a semicolon (;), or # character must precede any comments.
- If the same statement is encountered multiple times within a single TCPIP.DATA specification, the last statement takes effect. See the SEARCH, SORTLIST, NSINTERADDR/NAMESERVER, OPTIONS, and LOADDBCSTABLES statements for their unique processing of multiple statements.
- When Trace Resolver is in effect a warning message is written for any error in the specification of a statement or its parameters. The message is written to the specified Trace Resolver output location. Processing continues with the next line.
- Allocation errors (including volume offline conditions) cause the resolver service being requested to continue to be processed, but processing of TCPIP.DATA statements stops. Any already processed statements are used (for example, GLOBALTCPIPDATA statements). Defaults are assigned to any statements not specified.

If an allocation error occurs when trying to use TCPIP.DATA statements, a message is issued to the Joblog/STDOUT. If Trace Resolver is in effect, a message is also written to the specified Trace Resolver output location.

ALWAYSWTO statement

Some TCP/IP servers, such as SNMPQE, LPD, and Miscellaneous server, can use the ALWAYSWTO statement to issue all of their messages as Write To Operator (WTO) messages. This is in addition to their messages being sent to the server's MVS joblog output. Omitting the ALWAYSWTO statement causes the server messages to be sent only to the server's MVS job output.

Guideline: Do not specify ALWAYSWTO YES unless requested by IBM service. Specifying YES can generate a large volume of system operator console messages.

Syntax

Parameters

system_name:

The name of the system to which this statement applies. See [“system_name considerations” on page 311](#) for a complete description of this parameter.

Requirement: The colon is required.

YES

Indicates that server messages are to be displayed on the console.

NO

Indicates that server messages only go to the MVS output.

DATASETPREFIX statement

Use the DATASETPREFIX statement to set the high-level qualifier for the dynamic allocation of data sets in TCP/IP.

Syntax

➤ DATASETPREFIX — *dsprefix* ➤
 system_name:

Parameters

system_name:

The name of the system to which this statement applies. See [“system_name considerations” on page 311](#) for a complete description of this parameter.

Requirement: The colon is required.

dsprefix

The prefix to use as the high-level qualifier for the dynamic allocation of data sets. The default high-level qualifier distributed with the system is TCP/IP.

Guidelines: The values for the parameter must conform to the following rules:

- A maximum of 26 characters.
- Must contain one or more tokens separated by a period.
- Each token must be in the range 1 - 8 characters in length.
- Each token must start with a letter or character (\$, @, or #).
- Remaining characters in each token must be a letter, number, or character (-, \$, @, or #).
- The last character of the data set prefix must not be a period.

Examples

Code the following example to set the data set prefix for client and server usage to TCP/IP.V1R6:

```
DATASETPREFIX TCP/IP.V1R6
```

Usage notes

The DATASETPREFIX in TCP/IP.DATA is used by clients and servers except the TCP/IP address space.

DOMAIN statement

The DOMAIN statement is functionally equivalent to the DOMAINORIGIN statement. See [“DOMAINORIGIN statement” on page 316](#).

DOMAINORIGIN statement

Use the DOMAINORIGIN statement to specify the domain origin that is appended to the host name to form the fully qualified domain name of a host.

Syntax

```
DOMAINORIGIN — origin →
```

Parameters

system_name:

The name of the system to which this statement applies. See [“system_name considerations” on page 311](#) for a complete description of this parameter.

Requirement: The colon is required.

origin

The domain origin is appended to the host name. This name usually has imbedded dots.

Guidelines: The values for the domain name must conform to the following rules:

- Maximum of 249 characters.
- Must contain one or more tokens separated by a period.
- Each token must be at least one character.
- Each token must start with a letter or number.
- Remaining characters in each token must be a letter, number, or hyphen.
- The length of the host name plus the length of the domain name must be less than or equal to 254.

Steps for modifying

You can refresh this statement using the MODIFY command. For more information about parameters used with the [MODIFY command](#) command, see [z/OS Communications Server: IP System Administrator's Commands](#).

Examples

This example appends the domain origin of BOBS.YOUR.UNCLE to the host name:

```
DOMAINORIGIN BOBS.YOUR.UNCLE
```

Usage notes

- No case translation is performed on the domain origin.
- If the resolver is passed a host name that does not contain any dots (in dotted decimal notation), the domain origin is appended to the host name. If the host name passed to the resolver contains dots,

the value of the `OPTIONS NDOTS:n` statement influences how the `DOMAINORIGIN` value is used. See [“OPTIONS statement” on page 326](#).

- The `DOMAINORIGIN` configuration statement must be customized at each site.
- Additionally, the domain origin can be set from the z/OS shell environment by exporting the `LOCALDOMAIN` environment variable.

➤ `export — LOCALDOMAIN=origin` ➤

The setting of the `LOCALDOMAIN` as an environment variable overrides any setting for `DOMAIN`, `DOMAINORIGIN`, or `SEARCH` found in `TCPIP.DATA`.

HOSTNAME statement

Use the `HOSTNAME` statement to specify the TCP host name of this z/OS Communications Server server.

Syntax

➤ `system_name: HOSTNAME — host_name` ➤

Parameters

system_name:

The name of the system to which this statement applies. See [“system_name considerations” on page 311](#) for a complete description of this parameter.

Requirement: The colon is required.

host_name

The host name. If not specified or if not valid, the value is determined as follows:

- The system name specified in the `IEFSSNxx PARMLIB` member or on the `P` parameter of the `EZASSI` started procedure used for `restartable VMCF`. See [z/OS Communications Server: IP Configuration Guide](#) for details about configuring `VMCF`.
- If `VMCF` was not active at the time the TCP/IP stack was started, the `CVTSNAME` value (this is the `SYSNAME=value` in the `IEASYSxx PARMLIB` member A).

If the host name came from `TCPIP.DATA`, it is in the message case it was specified in on the `HOSTNAME` statement. For `VMCF` or `CVTSNAME`, the name is upper case.

The TCP/IP stack's configuration function uses the z/OS UNIX search order to locate the `TCPIP.DATA` `HOSTNAME` statement to determine the stack's host name. See [search orders used in the z/OS UNIX environment in the z/OS Communications Server: IP Configuration Guide](#) for a description of this search order. This host name value is the value that is returned on `gethostname` socket function calls processed by the stack. If the `HOSTNAME` statement is changed, TCP/IP needs to be restarted to pick up this change.

Guidelines: The values for the host name must conform to the following rules:

- Maximum of 63 characters.
- Must contain one or more tokens separated by a period.
- Each token must be at least one character and less than 64 characters.
- Each token must start with a letter or number.
- Remaining characters in each token must be a letter, number, or hyphen.

Examples

The TCPIP.DATA data set is shared between two systems, MVSMFG4 and MVSADM1. The HOSTNAME statements define the host name on each system.

```
MVSMFG4: HOSTNAME MVSMFG4  
MVSADM1: HOSTNAME MVSADM1
```

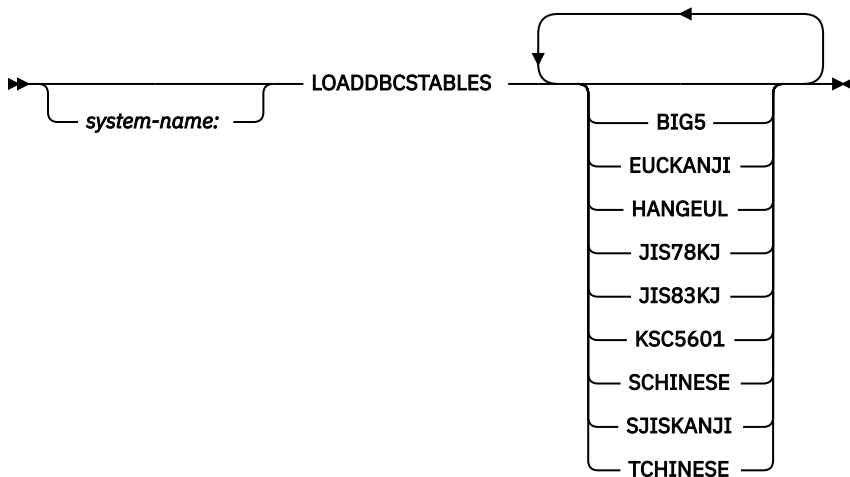

Usage notes

- No case translation is performed on the host name.
- See [z/OS Communications Server: IP Configuration Guide](#) for descriptions of [local host tables](#).

LOADDBCSTABLES statement

Use the LOADDBCSTABLES statement to indicate to the FTP server and client which DBCS translation tables can be loaded.

Syntax

Parameters

system_name:

The name of the system to which this statement applies. See [“system_name considerations” on page 311](#) for a complete description of this parameter.

Requirement: The colon is required.

BIG5

Indicates to the FTP server and client that the BIG5 DBCS translation table should be loaded from the TCPCHBIN binary translate table data set.

EUCKANJI

Indicates to the FTP server and client that the Extended UNIX Code Kanji DBCS translation table should be loaded from the TCPKJBIN binary translate table data set.

HANGEUL

Indicates to the FTP server and client that the Hangeul DBCS translation table should be loaded from the TCPHGBIN binary translate table data set.

JIS78KJ

Indicates to the FTP server and client that the JIS 1978 Kanji DBCS translation table should be loaded from the TCPKJBIN binary translate table data set.

JIS83KJ

Indicates to the FTP server and client that the JIS 1983 Kanji DBCS translation table should be loaded from the TCPKJBIN binary translate table data set.

KSC5601

Indicates to the FTP server and client that the Korean Standard Code KSC-5601 DBCS translation table should be loaded from the TCPHGBIN binary translate table data set.

SCHINESE

Indicates to the FTP server and client that the Simplified Chinese DBCS translation table should be loaded from the TCPSCBIN binary translate table data set.

SJISKANJI

Indicates to the FTP server and client that the Shift JIS Kanji DBCS translation table should be loaded from the TCPKJBIN binary translate table data set.

TCHINESE

Indicates to the FTP server and client that the Traditional Chinese (5550) DBCS translation table should be loaded from the TCPCHBIN binary translate table data set.

Examples

Load the Korean Standard Code KSC-5601 and the Traditional Chinese (5550) DBCS translation tables:

```
LOADDBCSTABLES KSC5601 TCHINESE
```

Usage notes

- You can select any or all of the translation tables or specify none. However, additional virtual storage might be required by the FTP server and client when a large number of translation tables are loaded at the same time.
- All the parameters must fit on one line. You can repeat the LOADDBCSTABLES statement as necessary to specify additional tables to be loaded.
- If the LOADDBCSTABLES parameter is not specified, is specified incorrectly, or if TCPIP.DATA is not accessible, then no DBCS translation tables are Reloaded, and the corresponding FTP server and client DBCS transfer types are unavailable.
- The IBMKANJI transfer type does not require any translation table to be loaded.
- If the same table name is specified more than one time, the subsequent specifications are ignored.

Related topics

See [z/OS Communications Server: IP Configuration Guide](#) for more information.

LOOKUP statement

Use the LOOKUP statement to specify the order in which the DNS or local host tables are to be used for name resolution.

Syntax

Parameters

system_name:

The name of the system to which this statement applies. See [“system_name considerations” on page 311](#) for a complete description of this parameter.

Requirement: The colon is required.

DNS

The domain name servers specified by the NSINTERADDR and NAMESERVER statements are used for name resolution. When system-wide caching is active, this processing includes querying the resolver cache first for entries provided by these name servers on previous name resolution attempts, and only if that query fails, querying the domain name servers.

For more resolver information see [z/OS Communications Server: IP Configuration Guide](#) for more details.

LOCAL

The local host tables (for example, etc/hosts, HOSTS.SITEINFO or HOSTS.ADDRINFO) are used for name resolution. See [z/OS Communications Server: IP Configuration Guide](#) for information about determining which [local host tables](#) are used.

Statement dependency

You can refresh this statement using the MODIFY command. For more information about parameters used with the [MODIFY command](#) command, see [z/OS Communications Server: IP System Administrator's Commands](#).

Examples

In the following example, only the local host tables are used:

```
LOOKUP LOCAL
```

In the following example, the local host tables are used first. If the resource name is not resolved, then the resolver cache (if a cache is being used) is used next. If there is still no resolution, then the name servers are queried directly.

```
LOOKUP LOCAL DNS
```

In the following example, the resolver cache (if a cache is being used) is used first. If the resource name is not resolved, then the name servers are queried directly. If there is still no resolution, then the local host tables are used next.

```
LOOKUP DNS LOCAL
```

Usage notes

- If a LOOKUP statement is not specified, the resolver cache (if a cache is being used) is queried first. If the cache query is unsuccessful, the domain name servers are queried next, and if the resolution request is not successful, the local host file, if it exists, is used.
- If an incorrect parameter value is specified, the entire LOOKUP statement is ignored.
- The last syntactically correct LOOKUP statement is used.

MESSAGECASE statement

Use the MESSAGECASE statement to specify whether to convert output into uppercase for the FTP server and some TSO commands.

Syntax

Parameters

system_name:

The name of the system to which this statement applies. See [“system_name considerations” on page 311](#) for a complete description of this parameter.

Requirement: The colon is required.

MIXED

Indicates that output should be displayed in mixed case. This is the default.

UPPER

Indicates that output should be displayed in uppercase.

Examples

To display all messages to the MVSTEST system in uppercase, use the following code:

```
MVSTEST: MESSAGECASE UPPER
```

Usage notes

- If you specify MIXED, no case conversion is performed on output.
- If the MESSAGECASE statement is not specified, is specified incorrectly, if MIXED or UPPER is not specified, or if TCPIP.DATA is not accessible, then mixed case output is displayed.
- All Writer To Operator (WTO) messages issued by the TCPIP stack are displayed in uppercase and are not affected by the MESSAGECASE value.
- Additionally, the MESSAGECASE statement can be set from the z/OS shell environment by exporting the MESSAGECASE environment variable. The MESSAGECASE environment variable is not supported by all functions. This is shown in the following example:

The diagram shows the export statement: `export MESSAGECASE=`. This is followed by a vertical line that branches into two paths: the top path is labeled **MIXED** and the bottom path is labeled **UPPER**. Both paths then merge back into a single horizontal line that ends with a double arrow pointing to the right.

The setting of the MESSAGECASE as an environment variable overrides any setting found in TCPIP.DATA. If MESSAGECASE is not defined as an environment variable or as a statement in TCPIP.DATA, the WTO message remains in mixed case.

NAMESERVER statement

The NAMESERVER statement is functionally equivalent to the NSINTERADDR statement. See [“NSINTERADDR statement” on page 323](#).

NOCACHE statement

Use the NOCACHE statement to indicate that results from application queries that are associated with this TCPIP.DATA file are not used to populate the system cache, nor are the contents of the system cache used to generate results to application queries.

For more information about resolvers see [z/OS Communications Server: IP Configuration Guide](#) for more details.

Syntax

➤ system_name: NOCACHE ➤

Parameters

system_name:

The name of the system to which this statement applies. See [“system_name considerations” on page 311](#) for a complete description of this parameter.

Requirement: The colon is required.

Steps for modifying

You can use the MODIFY command to change whether or not system-caching functions are used. If the NOCACHE statement is not in TCPIP.DATA, the current system-wide settings for use of the caching function should be used.

For more information about parameters used with the MODIFY command command, see [z/OS Communications Server: IP System Administrator's Commands](#).

NOCACHEREORDER statement

Use the NOCACHEREORDER statement to indicate that reordering of cached IP addresses is not performed for applications that use this TCPIP.DATA file. The NOCACHEREORDER statement is ignored if system-wide caching is not active, or if the NOCACHE statement is coded in this TCPIP.DATA file.

See [Cache reordering in z/OS Communications Server: IP Configuration Guide](#) for more information.

Syntax

➤ system_name: NOCACHEREORDER ➤

Parameters

system_name:

The name of the system to which this statement applies. See [“system_name considerations” on page 311](#) for a complete description of this parameter.

Requirement: The colon is required.

Steps for modifying

You can use the MODIFY command to change whether this application uses cache reordering. If the NOCACHEREORDER statement is not in the TCPIP.DATA file, the current system-wide settings for cache reordering are used.

For more information about parameters used with the MODIFY command command, see [z/OS Communications Server: IP System Administrator's Commands](#).

NSINTERADDR statement

Use the NSINTERADDR statement to define the IP address of a name server. The IP address can be either an IPv4 address or an IPv6 address.

See [z/OS Communications Server: IP Configuration Guide](#) for implications on coding an IPv6 address on this statement.

Syntax

Parameters

system_name:

The name of the system to which this statement applies. See [“system_name considerations” on page 311](#) for a complete description of this parameter.

Requirement: The colon is required.

internet_addr

The IP address of a name server.

Guidelines:

- You must code the values for a name server IPv4 address in dotted decimal format. The following restrictions apply:
 - You cannot specify the following IPv4 addresses as a valid name server IPv4 address:
 - IPv4 unspecified address (0.0.0.0)
 - IPv4 broadcast address
 - IPv4 multicast address
 - You cannot specify IPv4 subnet length information as part of the IPv4 address.
- You must code the values for a name server IPv6 address in colon hexadecimal format. You can specify the IPv6 addresses in upper case, lower case, or mixed case formats. The following restrictions apply:
 - You cannot specify the following IPv6 addresses as a valid name server IPv6 address:
 - IPv6 unspecified address (::)
 - IPv6 multicast address
 - IPv4-mapped IPv6 address
 - IPv6 address with the reserved prefix ::/96
 - You cannot specify scope information as part of the IPv6 address.
 - You cannot specify IPv6 prefix length information as part of the IPv6 address.

You can specify multiple IP addresses on a single NSINTERADDR statement. You can specify all IPv4 addresses, all IPv6 addresses, or a mixture of IPv4 and IPv6 addresses, in any order, on a single statement.

Steps for modifying

You can refresh this statement using the MODIFY command. For more information about parameters used with the [MODIFY command](#) command, see [z/OS Communications Server: IP System Administrator's Commands](#).

Examples

To specify the IP address of the name server to be 14.13.12.11, use the following code:

```
NSINTERADDR 14.13.12.11
```

To specify the IP address of the three name servers to be 14.13.12.11, 9.9.9.9, and 6.7.8.9, use the following code:

```
NSINTERADDR 14.13.12.11 9.9.9.9 6.7.8.9
```

An equivalent specification is:

```
NSINTERADDR 14.13.12.11
NSINTERADDR 9.9.9.9
NSINTERADDR 6.7.8.9
```

To specify the IP address of the name server to be 2001:0000:0000:0000:000E:000D:000C:000B, code any of these equivalent definitions:

```
NSINTERADDR 2001:0000:0000:0000:000E:000D:000C:000B
NSINTERADDR 2001::e:d:c:b
NSINTERADDR 2001:0:0:0:E:d:c:B
```

To specify the IP address of the three name servers to be 2001::e:d:c:b, 2001::9:9:9:9, and 2001:6:7:8:9, use the following code:

```
NSINTERADDR 2001::e:d:c:b 2001::9:9:9:9 2001::6:7:8:9
```

An equivalent specification is:

```
NSINTERADDR 2001::e:d:c:b
NSINTERADDR 2001::9:9:9:9
NSINTERADDR 2001::6:7:8:9
```

To specify a mixture of IPv4 and IPv6 name server IP addresses, for example ::1, 14.13.12.11, 9.9.9.9, and 2001:6:7:8:9, use the following code:

```
NSINTERADDR ::1 14.13.12.11 9.9.9.9 2001::6:7:8:9
```

An equivalent specification is:

```
NSINTERADDR ::1
NSINTERADDR 14.13.12.11
NSINTERADDR 9.9.9.9
NSINTERADDR 2001::6:7:8:9
```

Usage notes

- Up to 16 name server IP addresses can be specified. Any IP addresses beyond 16 are ignored.
- Connections to the name servers are attempted in the order they appear in the TCPIP.DATA data set.

If network DNS response message sizes tend to be larger than 512 bytes, put name servers that support Extension Mechanisms for DNS (EDNS0) before name servers that do not support EDNS0. The z/OS resolver supports UDP message sizes as large as 3072 bytes when communicating with name servers that support EDNS0. Ordering the name servers in terms of EDNS0 support can potentially avoid the use of more expensive TCP protocols when processing large DNS response messages.

- If resolver caching is in effect, the resolver cache is searched first before connections to any of the name servers are attempted. If valid, non-expired response data for the target resource has been

received and cached from any name server in the list, the resolver uses that data and does not send queries to any name servers. If response data for the target resource has been received and cached from more than one name server in the list, the resolver chooses the response data to be returned based on the order of the name servers in the TCPIP.DATA data set.

- If no NSINTERADDR statements are coded, the resolver does not attempt to use a name server. Instead, the resolver uses the local host tables as described in z/OS Communications Server: IP Configuration Guide to attempt to resolve the name or IP address.
- You can specify the same IP address multiple times.
- If you specify multiple name server IP addresses on a single NSINTERADDR statement, if any IP address is not an acceptable IP address, all IP addresses on the NSINTERADDR statement are ignored.
- After the resolver has successfully contacted a name server, it stops without contacting the remaining name servers for that query. Name servers beyond the first in the list are used only if the name server currently being contacted is down, or unreachable through the network.
- When the AUTOQUIESCE operand is specified on the UNRESPONSIVETHRESHOLD resolver setup statement, the resolver attempts to contact a name server for DNS queries generated by an application, based on whether the name servers specified on the NSINTERADDR statements are responsive.
 - If all name servers specified on the NSINTERADDR statements are responsive, or if all name servers are unresponsive, the resolver contacts all name servers in the list until a name server is successfully contacted or all attempts have failed.
 - If only a subset of name servers specified on the NSINTERADDR statements are responsive, the resolver attempts to contact only those name servers that are responsive, and does not send queries that are generated by an application to unresponsive name servers.

See the “UNRESPONSIVETHRESHOLD statement” on page 307 for more information about when the resolver considers a name server to be unresponsive.

- RESOLVERUDPRETRIES indicates the maximum number of times an attempt is made to reach a given name server if a response is not received within the current timeout interval. RESOLVERUDPRETRIES is applicable only if RESOLVEVIA UDP is coded or used by default.

Tip: RESOLVERTIMEOUT is the parameter used for the timeout value.

NSPORTADDR statement

Use the NSPORTADDR statement to specify the name server port number.

Syntax

Parameters

system_name:

The name of the system to which this statement applies. See “system_name considerations” on page 311 for a complete description of this parameter.

Requirement: The colon is required.

nsportaddr

The name server port number. The default is port 53.

Guidelines: The values for the name server port must conform to the following rules:

- Must be a single number.

- The number must be between one and five digits.
- The number cannot exceed 65 535.

Steps for modifying

You can refresh this statement using the [MODIFY command](#) command. For more information about parameters used with the [MODIFY command](#) command, see [z/OS Communications Server: IP System Administrator's Commands](#).

Examples

To specify the foreign port of the name server to be 55, use the following code:

```
NSPORTADDR 55
```

OPTIONS statement

Use the OPTIONS statement to specify:

- Whether or not resolver debug messages should be issued
- The number of periods (.) that need to be contained in a domain name for it to be considered a fully qualified domain name

Guideline: The NDOTS and DEBUG options are independent; setting one of them does not imply a setting for the other.

Syntax

Parameters

system_name:

The name of the system to which this statement applies. See [“system_name considerations”](#) on page 311 for a complete description of this parameter.

Requirement: The colon is required.

DEBUG

Specifying DEBUG is equivalent to the Trace Resolver statement. Debugging messages from the resolver are generated.

If OPTIONS DEBUG is anywhere in the TCPIP.DATA file, then tracing is on. It should be the first statement in the TCPIP.DATA statements to get the maximum trace output. The initial default setting is for no debug messages to be specified. Do not specify OPTIONS DEBUG in the GLOBALTCPIPDATA file.

NDOTS:n

Specifies that for a domain name that contains *n* or more periods (.), the resolver should try to look up the name *as is* before applying the DOMAINORIGIN or SEARCH statement settings.

Requirement: The colon is required.

A maximum of 15 is allowed for *n*. Any value for *n* not in the range 1 - 15 results in *n* being set to 1. Not specifying the NDOTS:*n* parameter results in the current setting remaining in effect (if no value has yet been specified on any previous OPTIONS statements, then NDOTS:1 is the setting).

Use care when setting *n* greater than 1. For example, consider the following:

- If NDOTS:2 was specified and the DOMAINORIGIN statement had mit.edu specified, the following results would be observed:
 - A user enters ftp prep.ai. Resolution of domain name prep.ai.mit.edu would be tried. If that fails resolution, then the name prep.ai would be tried.
 - A user enters ftp prep.ai.mit. The domain name prep.ai.mit would try to be resolved. If that fails resolution, then the name prep.ai.mit.mit.edu would be tried.
 - A user enters ftp prep. The domain name prep.mit.edu would try to be resolved. If that fails resolution, then the name prep would be tried.
- If NDOTS:1 was specified and the SEARCH statement had ai.mit.edu and MIT.EDU specified, the following results would be observed:
 - A user enters ftp prep.ai. The domain name prep.ai would try to be resolved. If that fails resolution, then the name prep.ai.ai.mit.edu would be tried. If that fails resolution, then the name prep.ai.MIT.EDU would be tried.
 - A user enters ftp prep. The domain name prep.ai.mit.edu would try to be resolved. If that fails resolution, then the name prep.MIT.EDU would be tried. If that fails resolution, then the name prep would be tried.
- If the name specified by the user ends with a period (.), then both the NDOTS:*n* specification and the DOMAINORIGIN or SEARCH values are ignored. For example, a user enters ftp prep.ai.. The domain name prep.ai. would try to be resolved. If that fails, no other name is tried.

Steps for modifying

You can refresh this statement using the `MODIFY command` command. For more information about parameters used with the `MODIFY command` command, see [z/OS Communications Server: IP System Administrator's Commands](#).

Examples

The following statement sets NDOTS to 2 and also requests resolver debug messages:

```
OPTIONS NDOTS:2 DEBUG
```

The following statement requests resolver debug messages and by default set NDOTS to 1:

```
OPTIONS DEBUG
```

The following set of statements in a single TCPIP.DATA file sets NDOTS to 3 and also request resolver debug messages:

```
OPTIONS NDOTS:2 DEBUG
OPTIONS NDOTS:3
```

The following set of statements in a single TCPIP.DATA file would set NDOTS to 3 and also request resolver debug messages.

```
OPTIONS NDOTS:2
OPTIONS NDOTS:3 DEBUG
OPTIONS
```

Usage notes

- If the OPTIONS statement is not specified or specified without a NDOTS:*n* parameter (for example, OPTIONS specified only with the DEBUG parameter), a value of :1 is assigned. Do not specify the OPTIONS DEBUG parameter in the GLOBALTCPIPDATA file.

Guideline: This assumes only one OPTIONS statement in the TCPIP.DATA file.

- If multiple OPTIONS NDOTS:*n* statements are encountered in a single TCPIP.DATA file, the last statement takes effect.
- If an OPTIONS statement without the DEBUG parameter is specified, the previous debug setting stays in effect. The default setting is for no debug messages to be specified.

Related topics

- [“DOMAINORIGIN statement” on page 316](#)
- [“SEARCH statement” on page 332](#)
- [“TRACE RESOLVER statement” on page 337](#)
- [z/OS Communications Server: IP Configuration Guide](#)
- You can also use the CTRACE TRACERES option to collect Trace Resolver output. For more information, see [CTRACE - RESOLVER](#) in [z/OS Communications Server: IP Diagnosis Guide](#).

RESOLVERTIMEOUT statement

Use the RESOLVERTIMEOUT statement to specify the amount of time the resolver waits for a response while trying to communicate with a name server when using UDP. See [“RESOLVEVIA statement” on page 331](#).

Syntax

Parameters

system_name:

The name of the system to which this statement applies. See [“system_name considerations” on page 311](#) for a complete description of this parameter.

Requirement: The colon is required.

time_out_value

The time the resolver waits until a response is received from a name server. The time can be specified in whole seconds, milliseconds, or a combination of both. For example, the RESOLVERTIMEOUT value can be 11, .110, or 1.100.

A *time_out_value* value that is less than 10 milliseconds is set to 10 milliseconds (0.010). For example, RESOLVERTIMEOUT 0.005 is processed as RESOLVERTIMEOUT 0.010.

A *time_out_value* value of 0 is equivalent to RESOLVERTIMEOUT 1.

Specifying more than three decimal positions is considered a parse error and is ignored. For example, RESOLVERTIMEOUT 0.0100 is a parse error and is not processed.

The default timeout value is 5 seconds; the maximum timeout value is 2147483.647.

Steps for modifying

You can refresh this statement using the MODIFY command. For more information about parameters used with the [MODIFY command](#) command, see [z/OS Communications Server: IP System Administrator's Commands](#).

Examples

Specify a 10 second *time_out_value* value:

```
RESOLVERTIMEOUT 10
```

Specify a half second *time_out_value* value:

```
RESOLVERTIMEOUT .5
```

Specify a 75 millisecond *time_out_value* value:

```
RESOLVERTIMEOUT .075
```

Specify a 3 and one half second *time_out_value* value:

```
RESOLVERTIMEOUT 3.50
```

Usage notes

The resolver uses the RESOLVERTIMEOUT value when it is waiting for a response to a resolver DNS polling query. The resolver sends resolver DNS polling queries to a name server when AUTOQUIESCE is specified on the UNRESPONSIVETHRESHOLD resolver setup statement and the name server is considered unresponsive. If the RESOLVERTIMEOUT value is changed using the MODIFY RESOLVER,REFRESH command, the new time value applies only to resolver DNS polling queries that are sent by the resolver after the MODIFY command is processed. See [“UNRESPONSIVETHRESHOLD statement”](#) on page 307 for more information about when the resolver considers a name server to be unresponsive.

Guideline: If you use the autonomic quiescing of unresponsive name servers function, you should specify a timeout value of 5 seconds or less.

The BIND 9 DNS utilities provide their own resolver that supports RESOLVERTIMEOUT values in seconds. If a *time_out_value* of less than 1 second is specified, these resolvers use a one second timeout. For a *time_out_value* of seconds.milliseconds, the specified seconds are used as the timeout value.

Be careful when assigning a short *time_out_value*. A number too small can result in timeouts occurring even when the network or name server is available, but due to high usage volume, it cannot respond quickly. Review the RESOLVERUDPRETRIES statement to see if a higher value should be specified for the maximum number of tries the resolver can make when using a name server.

Tip: Timeout conditions can cause the z/OS resolver to mistakenly act as though the name server does not support Extension Mechanism for DNS (EDNS0). This can prevent the z/OS resolver from using EDNS0 when it could otherwise be used; this behavior can adversely affect performance. For more information about EDNS0 processing, see [z/OS Communications Server: IP Configuration Guide](#).

Guideline: The resolver uses the API services of z/OS Unix System Services to manage the *time_out_value* value. z/OS Unix System Services uses the following criteria for timer resolution, if the *time_out_value* is one of the following values:

- Less than 1 second, the timer resolution is set to the next microsecond.
- Greater than 1 second, the timer resolution is set to the next second.

RESOLVERUDPRETRIES statement

Use the RESOLVERUDPRETRIES statement to specify the number of times (including retries) the resolver should try to connect to the name server when using UDP datagrams.

Syntax

Parameters

system_name:

The name of the system to which this statement applies. See [“system_name considerations” on page 311](#) for a complete description of this parameter.

Requirement: The colon is required.

limit

The maximum number of times the resolver should try to connect to the name server. The default is 1; the maximum number can be 2 147 483 647.

Steps for modifying

You can refresh this statement using the MODIFY command. For more information about parameters used with the [MODIFY command](#) command, see [z/OS Communications Server: IP System Administrator's Commands](#).

Examples

To specify 2 as the number of times the resolver tries to connect to the name server when using UDP datagrams, use the following code:

```
RESOLVERUDPRETRIES 2
```

Usage notes

- This statement applies only when using UDP datagrams. See [“RESOLVEVIA statement” on page 331](#) for more information.
- The resolver attempts to contact each of the specified name servers before attempting any retries.
- The maximum amount of time for each UDP resolution is the product of the number of name servers (NSINTERADDR/NAMERSERVER statements) multiplied by the resolver timeout value (RESOLVERTIMEOUT statement) multiplied by the number of times to try the name servers (RESOLVERUDPRETRIES statement). This amount of time can occur for each domain name specified by the SEARCH statement. If a getaddrinfo API call is issued to request a query for both IPv4 and IPv6 addresses, the maximum amount of time can be doubled.
- A RESOLVERUDPRETRIES value of zero indicates that the resolver should not attempt to contact any name servers.
- Use the DIG command with the STATS option to determine how many attempts it takes for each DNS in the NSINTERADDR list to respond. Set RESOLVERUDPRETRIES to the number of attempts for the least responsive DNS in the list, and place the least responsive DNSs at the end of the list.
- If network DNS response message sizes tend to be larger than 512 bytes, put name servers that support Extension Mechanisms for DNS (EDNS0) before name servers that do not support EDNS0. The z/OS resolver supports UDP message sizes as large as 3 072 bytes when communicating with name servers that support EDNS0. Ordering the name servers in terms of EDNS0 support can potentially avoid the use of more expensive TCP protocols when processing large DNS response messages.

RESOLVEVIA statement

Use the RESOLVEVIA statement to specify the protocol used by the resolver to communicate with the name server.

Guideline: If you use the autonomic quiescing of unresponsive name servers function, you should use UDP as your protocol to communicate with the name server.

Syntax

Parameters

system_name:

The name of the system to which this statement applies. See [“system_name considerations” on page 311](#) for a complete description of this parameter.

Requirement: The colon is required.

UDP

Specifies that the protocol is UDP. The default protocol is UDP.

TCP

Specifies that the protocol is TCP.

If anything other than UDP or TCP is specified, the default of UDP is used.

Steps for modifying

You can refresh this statement using the MODIFY command. For more information about parameters used with the [MODIFY command](#) command, see [z/OS Communications Server: IP System Administrator's Commands](#).

Examples

To specify that the resolver is to communicate with the name server using TCP virtual circuits, code the following:

```
RESOLVEVIA TCP
```

Usage notes

When RESOLVEVIA UDP is specified, the resolver primarily uses the UDP protocol but can switch to TCP protocols under certain conditions. The resolver is most likely to switch to TCP protocols when a DNS reply from the name server is truncated. Even though the resolver supports Extension Mechanisms for DNS0 (EDNS0) standards and accepts up to 3072 bytes of reply data, not all DNS name servers support EDNS0. Firewall settings along the path to the name server can also limit the number of bytes in a resolver UDP reply. To maximize the use of UDP protocols by the resolver, configure firewalls such that the TCP and UDP ports to and from the name servers are allowed to pass the larger EDNS0 packets.

For more information about [ENDS0 processing](#), see [z/OS Communications Server: IP Configuration Guide](#).

SEARCH statement

Use the SEARCH statement to specify the list of domain names that are appended, in the order listed, to the host name to form the fully qualified domain name of a host. A domain name is appended until either the list is exhausted or an IP address is determined. The domain names are appended for name server queries as well as for searching the local host tables.

Syntax

Parameters

system_name:

The name of the system to which this statement applies. See [“system_name considerations” on page 311](#) for a complete description of this parameter.

Requirement: The colon is required.

domain

The domain name is appended to the host name. This name usually has imbedded dots.

For name query performance reasons, the first domain listed should be the most likely to respond to a name query. See [“DOMAINORIGIN statement” on page 316](#) for the rules for the domain name values. See [“RESOLVERTIMEOUT statement” on page 328](#) and [“RESOLVERUDPREDRIES statement” on page 329](#) for details. No case translation is performed on the domain name.

Up to six names separated by at least one blank are allowed. If the domain names cannot fit on a single SEARCH statement, multiple SEARCH statements can be used. If more than six domain names are specified, only the first six are used. The first domain name specified is used as the value for DOMAINORIGIN/DOMAIN. If both the SEARCH and DOMAINORIGIN/DOMAIN statements are present, the one that appears last is used. Encountering a DOMAINORIGIN/DOMAIN statement after SEARCH statements results in the DOMAINORIGIN's value as the only domain name.

Steps for modifying

You can refresh this statement using the MODIFY command. For more information about parameters used with the [MODIFY command](#), see [z/OS Communications Server: IP System Administrator's Commands](#).

Examples

The following example would establish a search list:

```
SEARCH  raleigh.ibm.com  US.IBM.COM  ibm.com
```

An equivalent specification is:

```
SEARCH raleigh.ibm.com
SEARCH US.IBM.COM
SEARCH ibm.com
```

If a user entered FTP RALVM12 and assuming that [OPTIONS NDOTS:n](#) (see [“OPTIONS statement” on page 326](#)) was specified such that the SEARCH domains should be appended, the following order of name

queries would be done in sequence by the resolver until either an answer was found, or the list was exhausted:

1. RALVM12.raleigh.ibm.com
2. RALVM12.US.IBM.COM
3. RALVM12.ibm.com

Related topics

- [“DOMAINORIGIN statement” on page 316](#)
- [“OPTIONS statement” on page 326](#)
- [z/OS Communications Server: IP Configuration Guide](#)

SOCKDEBUG statement

Use the SOCKDEBUG statement to turn on the tracing of TCP/IP socket library calls. This statement produces trace messages only for sockets using the TCP/IP C sockets or TCP/IP REXX sockets application programming interfaces.

Syntax

```
➤ _____ SOCKDEBUG ➤  
  |  
  | system_name: |
```

Parameters

system_name:

The name of the system to which this statement applies. See [“system_name considerations” on page 311](#) for a complete description of this parameter.

Requirement: The colon is required.

Usage notes

This statement works for all TCP/IP C sockets across the system the way sock_debug() works for a specific socket application.

Related topics

See [z/OS Communications Server: IP Sockets Application Programming Interface Guide and Reference](#) for more information about [sockets](#).

SOCKNOTESTSTOR statement

Use the SOCKNOTESTSTOR statement to stop checking of TCP/IP C sockets socket calls for storage access errors on the parameters to the call.

Syntax

```
➤ _____ SOCKNOTESTSTOR ➤  
  |  
  | system_name: |
```

Syntax

Parameters

system_name:

The name of the system to which this statement applies. See [“system_name considerations” on page 311](#) for a complete description of this parameter.

Requirement: The colon is required.

IPAddr

The subnet or network address.

The specification of the address can be:

- network/subnet mask; for example 128.32.42.0/255.255.255.0 or 128.32.42.0/24

The mask can be specified by a /xx. The number, denoted by xx, represents the number of significant bits in the mask, for example: /24=24 significant bits=11111111 11111111 11111111 00000000=255.255.255.0

- network; for example 128.32.0.0 or 9.0.0.0

If no mask is specified then the following mask is used:

- Class A network - 255.0.0.0
- Class B network - 255.255.0.0
- Class C network - 255.255.255.0
- Class D or E network - 255.255.255.255

Guidelines: The values for the SORTLIST IP address must conform to the following rules:

- Must contain four tokens, each separated by a period.
- Each token must be between one and three characters.
- Each character in each token must be a number.
- Each token cannot exceed the 255.

The values for the SORTLIST subnet mask:

- The short format is of the form x.x.x.x/y where:
 - x.x.x.x is the IP address
 - y is an integer from 1 to 32 representing the number of bits for the mask
- The full format is of the form x.x.x.x/y.y.y.y where:
 - x.x.x.x is the IP address
 - y.y.y.y is the mask (same syntax checking as IP address)

Steps for modifying

You can refresh this statement using the MODIFY command. For more information about parameters used with the [MODIFY command](#) command, see [z/OS Communications Server: IP System Administrator's Commands](#).

Examples

In this example, assume that your host has multiple subnet interfaces, for example, 128.32.42 for your internal network and 128.32.1 for Ethernet.

If you want your applications to use the internal subnet address before any other interface address, code the SORTLIST statement as follows:

```
SORTLIST 128.32.42.0/24
```

If you want your applications to use the internal network first, and then any other Class B interface for 128.32, code the SORTLIST statement as follows:

```
SORTLIST 128.32.42.0/24 128.32.0.0
```

Usage notes

- A maximum of four IP addresses is allowed. If the IP addresses cannot fit on a single SORTLIST statement, multiple SORTLIST statements can be used. If more than four are specified, only the first four IP addresses are used.
- SORTLIST is supported only for GETHOSTBYNAME and GETADDRINFO calls that return IPv4 addresses, and is not used for NSLOOKUP or ONSLOOKUP.
- Specifying the SORTLIST statement can affect the results of cache reordering for GETADDRINFO and GETHOSTBYNAME calls issued by the application that uses this TCPIP.DATA file. The resolver first reorders the cached list of IP addresses and then sorts the reordered list based on the SORTLIST specifications. If the SORTLIST statement is specified, the resolver might return the list of IP addresses in the same order to this application every time, regardless of the use of cache reordering.

TCPIPJOBNAME statement

Use the TCPIPJOBNAME statement to specify the member name of the procedure used to start the TCP/IP address space.

Syntax

Parameters

system_name:

The name of the system to which this statement applies. See [“system_name considerations” on page 311](#) for a complete description of this parameter.

Requirement: The colon is required.

tcpip_proc

The name of the member in the cataloged procedure library that is used to start the TCP/IP address space. In some cases, the default is TCPIP. However, for applications which use Language Environment services, the lack of a TCPIPJOBNAME statement causes applications that issue `__iptcpn()` to receive a *jobname* of NULL, rather than the default of TCPIP. Although this presents no problem when running in a single-stack environment, this can potentially cause errors in a multi-stack environment. The maximum length of the start procedure is 8 characters.

Examples

To specify TCPIPA as the name of the procedure that was used to start the TCP/IP address space, use the following code:

```
TCPIPJOBNAME TCPIPA
```

Usage notes

You must specify the proper procedure name of the TCP/IP address space on your system. If *tcip_proc* is not the name of the started TCP/IP address space, applications using any TCP/IP provided API fail with an irrecoverable interaddress communication error.

For more information about why the TCPIPJOBNAME parameter must match the name of the associated TCP/IP address space and be the same name as that defined for the corresponding AF_INET physical file system in the BPXPRMxx member used to configure z/OS UNIX, see [z/OS Communications Server: IP Configuration Guide](#).

TCPIPUSERID statement

The TCPIPUSERID statement is functionally equivalent to the TCPIPJOBNAME statement. See [“TCPIPJOBNAME statement” on page 336](#).

TRACE RESOLVER statement

Use the TRACE RESOLVER statement to have a complete trace of all queries to and responses from the name server issued. Specifying TRACE RESOLVER is equivalent to the OPTIONS DEBUG statement.

Restrictions:

- The TRACE RESOLVER statement should not be specified in the GLOBALTCIPDATA file. Before making a TCPIP.DATA file global, it should be tested for syntax errors. Trace output should appear in the SYSTCPT data set or RESOLVER_TRACE file that was specified.
- TRACE RESOLVER should be the first statement in the TCPIP.DATA statements to get the maximum trace output.

Syntax

➤ system_name: TRACE RESOLVER ➤

Parameters

system_name:

The name of the system to which this statement applies. See [“system_name considerations” on page 311](#) for a complete description of this parameter.

Requirement: The colon is required.

Steps for modifying

You can refresh this statement using the MODIFY command. For more information about parameters used with the [MODIFY command](#) command, see [z/OS Communications Server: IP System Administrator's Commands](#).

Examples

To do a complete trace of all queries to and from the name server, use the following code:

```
TRACE RESOLVER
```

Usage notes

The TRACE RESOLVER statement is used for debugging purposes only.

Related topics

- See [z/OS Communications Server: IP Diagnosis Guide](#) for information about interpreting and directing the output.
- You can also use the CTRACE TRACERES option to collect Trace Resolver output. For more information, see [CTRACE - RESOLVER](#) in [z/OS Communications Server: IP Diagnosis Guide](#).

TRACE SOCKET statement

Use the TRACE SOCKET statement to have a complete trace of all calls to TCP/IP through the C socket library.

Syntax

➤ system_name: TRACE SOCKET ➤

Parameters

system_name:

The name of the system to which this statement applies. See [“system_name considerations” on page 311](#) for a complete description of this parameter.

Requirement: The colon is required.

Examples

Do a complete trace of all TCP/IP C socket calls:

```
TRACE SOCKET
```

Usage notes

The TRACE SOCKET statement is used for debugging purposes only.

The output from the TRACE SOCKET command is sent to the data set referred to by the SYSPRINT DD statement.

; and # statements

Use the ; or # to indicate a comment. Any data after the ; or # character is treated as a comment.

Sample TCPIP.DATA data set (TCPDATA)

The following shows sample TCPIP.DATA statements that can be used to configure information used by the resolver and TCP/IP application programs. The sample is shipped as member TCPDATA in the z/OS Communications Server SEZAINST data set.

```
*****
;
;   Name of Data Set:      TCPIP.DATA
;
;   COPYRIGHT = NONE.
;
;   This data, TCPIP.DATA, is used to specify configuration
;   information required by TCP/IP client and server programs.
;
;
;   Syntax Rules for the TCPIP.DATA configuration data set:
;
;   (a) All characters to the right of and including a ; or # will
;       be treated as a comment.
;
;   (b) Blanks and <end-of-line> are used to delimit tokens.
;
;   (c) The format for each configuration statement is:
;
;       <SystemName||':>' keyword value
;
;       where <SystemName||':>' is an optional label that can be
;       specified before a keyword; if present, then the keyword-
;       value pair will only be recognized if the SystemName matches
;       the name of the MVS system.
;       SystemName is derived from the MVS image name. Its value should
;       be the IEASYSxx parmlib member's SYSNAME= parameter value.
;       The SystemName can be specified by either restartable VMCF
;       or the subsystem definition of VMCF in the IEFSSNxx member of
;       PARMLIB.
;
;
;   (d) There should be no sequence numbers in this dataset. If there
;       are they can be treated as invalid statement parameters.
;
*****
;
; TRACE RESOLVER statement
; =====
; TRACE RESOLVER will cause a complete trace of all queries to and
; responses from the name server or site tables.
; This command is for debugging purposes only.
; It should be the first statement in the TCPIP.DATA statements to get
; the maximum trace output.
;
; TRACE RESOLVER
;
;
; OPTIONS statement
; =====
; Use the OPTIONS statement to specify the following:
; DEBUG
;   Causes resolver debug messages to be issued. This is equivalent to
;   TRACE RESOLVER. If used it should be the first statement in the
;   TCPIP.DATA statements to get the maximum trace output.
; NDOTS:n
;   Indicates the number of periods (.) that need to be contained in a
;   domain name for it to be considered a fully qualified domain name
;
; OPTIONS NDOTS:1 DEBUG
;
;
; TCPIPJOBNAME statement
; =====
; TCPIPJOBNAME specifies the name of the started procedure that was
; used to start the TCPIP address space. TCPIP is the default for
; most cases. However, for applications which use Language Environment
; services, the lack of a TCPIPJOBNAME statement causes applications
; that issue __iptcpn() to receive a jobname of NULL, and some of these
; applications will use INET instead of TCPIP. Although this presents
```

```

; no problem when running in a single-stack environment, this can
; potentially cause errors in a multi-stack environment.
;
; If multiple TCPIP stacks are run on a single system, each stack will
; require its own copy of this file, each with a different value for
; TCPIPJOBNAME.
;
TCPIPJOBNAME TCPIP
;
;
; HOSTNAME statement
; =====
; HOSTNAME specifies the TCP host name of this system as it is known
; in the IP network. If not specified, the default HOSTNAME will be
; the name specified by either restartable VMCF or the subsystem
; definition of VMCF in the IEFSSNxx member of PARMLIB.
; If the VMCF name is not available then the IEASYSxx parmlib member's
; SYSNAME= parameter value will be used.
;
; For example, if this TCPIP.DATA data set is shared between 2
; systems, OURMVSNAM and YOURMVSNAM, then the following 2 lines
; will define the HOSTNAME correctly on each system.
;
; OURMVSNAM:    HOSTNAME  OURTCPNAME
; YOURMVSNAM:   HOSTNAME  YOURTCPNAME
;
; No prefix is required if the TCPIP.DATA file is not being shared.
;
; HOSTNAME THISTCPNAME
;
;
; NOTE - Use either DOMAINORIGIN/DOMAIN or SEARCH to specify your domain
;        origin value
;
; DOMAINORIGIN or DOMAIN statement
; =====
; DOMAINORIGIN or DOMAIN specifies the domain origin that will be
; appended to host names passed to the resolver. If a host name
; ends with a dot, then the domain origin will not be appended to the
; host name.
;
; DOMAINORIGIN  YOUR.DOMAIN.NAME
;
;
; SEARCH statement
; =====
; SEARCH specifies a list of 1 to 6 domain origin values that will be
; appended to host names passed to the resolver. If a host name
; ends with a dot, then none of the domain origin values will be
; appended to the host name.
; The first domain origin value specified by SEARCH will be used as the
; DOMAINORIGIN/DOMAIN value.
;
; SEARCH YOUR.DOMAIN.NAME my.domain.name domain.name
;
;
; DATASETPREFIX statement
; =====
; DATASETPREFIX is used to set the high level qualifier for dynamic
; allocation of data sets in TCP/IP.
;
; The character string specified as a parameter on
; DATASETPREFIX takes precedence over the default prefix of "TCPIP".
;
; The DATASETPREFIX parameter can be up to 26 characters long
; and the parameter must NOT end with a period.
;
; For more information please see "Dynamic Data Set Allocation" in
; the IP Configuration Guide.
;
DATASETPREFIX TCPIP
;
;
; MESSAGECASE statement
; =====
; MESSAGECASE MIXED indicates to some servers, such as FTPD, that
; messages should be displayed in mixed case. MESSAGECASE UPPER
; indicates that all messages should be displayed in uppercase. Mixed
; case strings that are inserted in messages will not be uppercased.
;
; If MESSAGECASE is not specified, mixed case messages will be used.
;

```

```

; MESSAGECASE MIXED
; MESSAGECASE UPPER
;
;
; NOCACHE statement
; =====
; NOCACHE specifies that resolver cache processing should not be used.
; If NOCACHE is not specified, then the current system-wide level of
; resolver caching is used.
;
; NOCACHE
;
; NOCACHEREORDER statement
; =====
; NOCACHEREORDER specifies that the resolver should not reorder
; the list of cached IP addresses when responding to a resolution
; request for the associated host name. If NOCACHEREORDER is not
; specified, then the current system-wide setting for cache entry
; reordering is used.
;
; NOCACHEREORDER
;
; NSINTERADDR or NAMESERVER statement
; =====
; NSINTERADDR or NAMESERVER specifies the IP address of a name server.
;
; If you do not use name servers, then do not code any NSINTERADDR or
; NAMESERVER statements. If you do have name servers, then code the
; IPv4 or IPv6 address of the remote name servers to be contacted.
;
; The NSINTERADDR or NAMESERVER statement can be repeated up to sixteen
; times to specify alternate name servers. The name server listed first
; will be the first one attempted.
;
; IPv4 name server address:
; NSINTERADDR 10.0.0.1
;
; Ipv6 name server address:
; NSINTERADDR fc00::1
;
; NSPORTADDR statement
; =====
; NSPORTADDR specifies the foreign port of the name server.
; 53 is the default value.
;
; NSPORTADDR 53
;
; RESOLVEVIA statement
; =====
;
; RESOLVEVIA specifies how the resolver is to communicate with the
; name server. TCP indicates use of TCP connections. UDP indicates
; use of UDP datagrams. The default is UDP.
;
; RESOLVEVIA UDP
;
;
; RESOLVERTIMEOUT statement
; =====
; RESOLVERTIMEOUT specifies the time that the resolver will wait for
; a response from the name server when using RESOLVEVIA UDP.
; The default is 5 seconds.
;
; RESOLVERTIMEOUT 5
;
;
; RESOLVERUDPRETRIES statement
; =====
;
; RESOLVERUDPRETRIES specifies the number of times the resolver
; should try to connect to the name server when using UDP datagrams.
; The default is 1.
;
; RESOLVERUDPRETRIES 1
;
;
; LOOKUP statement
; =====
; LOOKUP indicates the order of name and address resolution. DNS means
; use the DNSs listed on the NSINTERADDR and NAMESERVER statements.

```

```

; LOCAL means use the local host tables as appropriate for the
; environment being used (UNIX System Services or Native MVS).
;
; LOOKUP DNS LOCAL
;
;
; LOADDBCSTABLES statement
; =====
; LOADDBCSTABLES indicates to the FTP server and FTP client which DBCS
; translation tables should be loaded at initialization time. Remove
; from the list any tables that are not required. If LOADDBCSTABLES is
; not specified, no DBCS tables will be loaded.
;
; LOADDBCSTABLES JIS78KJ JIS83KJ SJISKANJI EUCKANJI HANGEUL KSC5601
; LOADDBCSTABLES TCHINESE BIG5 SCHINESE
;
;
; SOCKDEBUG statement
; =====
; Use the SOCKDEBUG statement to turn on the tracing of TCP/IP C and
; REXX socket library calls.
; This command is for debugging purposes only.
;
; SOCKDEBUG
;
;
; SOCKNOTESTSTOR statement
; =====
; SOCKTESTSTOR is used to check socket calls for storage access errors
; on the parameters to the call. SOCKNOTESTSTOR stops this checking
; and is better for response time. SOCKNOTESTSTOR is the default.
;
; SOCKTESTSTOR
; SOCKNOTESTSTOR
;
;
; SORTLIST statement
; =====
; Use the SORTLIST statement to specify the ordered list (maximum of 4)
; of network numbers (subnets or networks) for the resolver to prefer
; if it receives multiple addresses as the result of a name query.
;
; SORTLIST 128.32.42.0/24 128.32.42.0/255.255.0.0 9.0.0.0
;
;
; TRACE SOCKET statement
; =====
; TRACE SOCKET will cause a complete trace of all calls to TCP/IP
; through the C socket library.
; This statement is for debugging purposes only.
;
; TRACE SOCKET
;
;
; ALWAYSWT0 statement
; =====
;
; ALWAYSWT0 causes messages for some servers, such as LPD,
;
; to be issued as WT0s. Specifying YES can cause excessive operator
; console messages to be issued.
;
; ALWAYSWT0 NO
; ALWAYSWT0 YES
;
; Obsolete statements
; =====
; The following statements no longer have any effect when included in
; this file:
;   SOCKBULKMODE
;   SOCKDEBUGBULKPERF0
;
; End of file.
;

```

Figure 7. Sample TCPIP.DATA data set (TCPDATA)

Resolver configuration statements for IBM z/OS Container Platform environments

The configuration statements for IBM z/OS Container Platform are obtained from the z/OS UNIX files `/etc/resolv.conf` and `/etc/nsswitch.conf` in the container's filesystem namespace. The `/etc/resolv.conf` configuration statements are summarized in [Table 10 on page 343](#).

Table 10. Summary of `/etc/resolv.conf` configuration statements

Statement	Description	See
NAMESERVER	Define the IP address of a name server. The IP address can be either IPv4 or IPv6.	NAMESERVER statement
OPTIONS NDots	Specify the number of periods (.) that need to be contained in a domain name for it to be considered a fully qualified domain name.	OPTIONS statement
SEARCH	Specify the list of domain names that are appended, in the order listed, to the host name to form the fully qualified domain name of a host.	SEARCH statement
TCPIPJOBNAME	Specify the member's name of the cataloged procedure used to start the TCPIP address space.	TCPIPJOBNAME statement

The `/etc/resolv.conf` configuration statements are summarized in [Table 11 on page 343](#).

Table 11. Summary of `/etc/nsswitch.conf` configuration statements

Statement	Description	See
HOSTS	Specify the order in which the DNS or local files are to be used for host name resolution for IBM z/OS Container Platform environments.	HOSTS statement

Syntax conventions for resolver configuration statements for IBM z/OS Container Platform environments

Note: The z/OS UNIX files `/etc/resolv.conf` and `/etc/nsswitch.conf` are automatically generated when the container/Pod is started. These files are created based on the resolver environment of the caller starting the container/Pod. Typically, the contents of these two files do not need to be modified once the container/Pod is running.

Observe the following syntax conventions for resolver configuration statements:

- The z/OS UNIX file containing the resolver configuration statements can have a maximum line length of 256.
- Only one statement is allowed on each line.
- A statement can start in any position on a line.
- Statements are not case sensitive.
- A blank line is treated as a comment.
- For statements with a single parameter value or no parameter value, a blank after the value ends the statement. Anything on the line following the blank is treated as a comment.
- For statements accepting multiple parameter values (for example, SEARCH, NAMESERVER and OPTIONS NDOTS), at least one blank followed by either a semicolon (;), or # character must precede any comments.

- Any resolver APIs will fail with error code EZB_RSN_ConfigNotFound when the z/OS UNIX file ‘/etc/resolv.conf’ is not found in the container’s filesystem namespace.

Dynamically changing resolver configuration statements for IBM z/OS Container Platform environments

You can use the MODIFY RESOLVER,REFRESH command to change the resolver configuration statements being used by a long-running application in an IBM z/OS Container Platform environment (for example, a server application). To do this, use the following procedure.

Table 9 on page 312 lists the resolver configuration statements and whether each statement can be dynamically changed (refreshed). For more information about [MODIFY command](#), see [z/OS Communications Server: IP System Administrator's Commands](#) and [z/OS Communications Server: IP Configuration Guide](#) for information about [configuring resolvers](#).

Steps for dynamically changing the resolver configuration statements for IBM z/OS Container Platform environments:

Procedure

Perform the following steps to dynamically change resolver configuration statements.

1. Change the z/OS UNIX file ‘/etc/resolv.conf’, found in the container’s filesystem namespace, currently being used by the container for resolver configuration to the new values.
2. To use the changed values, issue the MODIFY RESOLVER,REFRESH command. When application programs that are configured to use the TCPIP.DATA file make their next resolver socket call (for example, gethostbyaddr or gethostbyname), the new values are used.

Note: This command causes applications in all IBM z/OS Container Platform environments to reread their resolver configuration, not just in the IBM z/OS Container Platform environment where the resolver configuration was changed.

NAMESERVER statement

Use the **NAMESERVER** statement to define the IP address of a name server. The IP address can be either an IPv4 address or an IPv6 address. See [z/OS Communications Server: IP Configuration Guide](#) for implications on coding an IPv6 address on this statement.

Syntax

Parameters

internet_addr:

The IP address of a name server.

Guidelines:

- You must code the values for a name server IPv4 address in dotted decimal format. The following restrictions apply:
 - You cannot specify the following IPv4 addresses as a valid name server IPv4 address:
 - IPv4 unspecified address (0.0.0.0)
 - IPv4 broadcast address
 - IPv4 multicast address
 - You cannot specify IPv4 subnet length information as part of the IPv4 address.

- You must code the values for a name server IPv6 address in colon hexadecimal format. You can specify the IPv6 addresses in upper case, lower case, or mixed case formats. The following restrictions apply:
 - You cannot specify the following IPv6 addresses as a valid name server IPv6 address:
 - IPv6 unspecified address (::)
 - IPv6 multicast address
 - IPv4-mapped IPv6 address
 - IPv6 address with the reserved prefix ::/96
 - You cannot specify scope information as part of the IPv6 address.
 - You cannot specify IPv6 prefix length information as part of the IPv6 address.

You can specify multiple IP addresses on a single **NAMESERVER** statement. You can specify all IPv4 addresses, all IPv6 addresses, or a mixture of IPv4 and IPv6 addresses, in any order, on a single statement.

Steps for modifying

You can refresh this statement using the MODIFY command. For more information about parameters used with the [MODIFY command](#) command, see [z/OS Communications Server: IP System Administrator's Commands](#).

Examples

To specify the IP address of the name server to be 14.13.12.11, use the following code:

```
NAMESERVER 14.13.12.11
```

To specify the IP address of the three name servers to be 14.13.12.11, 9.9.9.9, and 6.7.8.9, use the following code:

```
NAMESERVER 14.13.12.11 9.9.9.9 6.7.8.9
```

An equivalent specification is:

```
NAMESERVER 14.13.12.11
NAMESERVER 9.9.9.9
NAMESERVER 6.7.8.9
```

To specify the IP address of the name server to be 2001:0000:0000:0000:000E:000D:000C:000B, code any of these equivalent definitions:

```
NAMESERVER 2001:0000:0000:0000:000E:000D:000C:000B
NAMESERVER 2001::e:d:c:b
NAMESERVER 2001:0:0:0:E:d:c:B
```

To specify the IP address of the three name servers to be 2001::e:d:c:b, 2001::9:9:9:9, and 2001:6:7:8:9, use the following code:

```
NAMESERVER 2001::e:d:c:b 2001::9:9:9:9 2001:6:7:8:9
```

An equivalent specification is:

```
NAMESERVER 2001::e:d:c:b
NAMESERVER 2001::9:9:9:9
NAMESERVER 2001:6:7:8:9
```

To specify a mixture of IPv4 and IPv6 name server IP addresses, for example ::1, 14.13.12.11, 9.9.9.9, and 2001:6:7:8:9, use the following code:

```
NAMESERVER ::1 14.13.12.11 9.9.9.9 2001::6:7:8:9
```

An equivalent specification is:

```
NAMESERVER ::1  
NAMESERVER 14.13.12.11  
NAMESERVER 9.9.9.9  
NAMESERVER 2001::6:7:8:9
```

Usage notes

- Up to 16 name server IP addresses can be specified. Any IP addresses beyond 16 are ignored.
- Connections to the name servers are attempted in the order they appear in the Unix file /etc/resolv.conf file in the container's filesystem namespace. If network DNS response message sizes tend to be larger than 512 bytes, put name servers that support Extension Mechanisms for DNS (EDNS0) before name servers that do not support EDNS0. The z/OS resolver supports UDP message sizes as large as 3072 bytes when communicating with name servers that support EDNS0. Ordering the name servers in terms of EDNS0 support can potentially avoid the use of more expensive TCP protocols when processing large DNS response messages.
- If no NAMESERVER statements are coded, the resolver does not attempt to use a name server. Instead, the resolver uses the local host tables as described in [z/OS Communications Server: IP Configuration Guide](#) to attempt to resolve the name or IP address.
- You can specify the same IP address multiple times.
- If you specify multiple name server IP addresses on a single NAMESERVER statement, if any IP address is not an acceptable IP address, all IP addresses on the NAMESERVER statement are ignored.
- After the resolver has successfully contacted a name server, it stops without contacting the remaining name servers for that query. Name servers beyond the first in the list are used only if the name server currently being contacted is down, or unreachable through the network.

OPTIONS NDOTS statement

Use the OPTIONS statement to specify:

The number of periods (.) that need to be contained in a domain name for it to be considered a fully qualified domain name.

Syntax

Parameters

NDOTS:n

Specifies that for a domain name that contains n or more periods (.), the resolver should try to look up the name as is before applying the SEARCH statement settings.

Requirement: The colon is required.

A maximum of 15 is allowed for n. Any value for n not in the range 1 - 15 results in n being set to 1. Not specifying the NDOTS:n parameter results in the current setting remaining in effect (if no value has yet been specified on any previous OPTIONS statements, then NDOTS:1 is the setting).

Use care when setting *n* greater than 1. For example, consider the following:

- If NDOTS:1 was specified and the SEARCH statement had ai.mit.edu and MIT.EDU specified, the following results would be observed:
 - A user enters ftp prep.ai. The domain name prep.ai would try to be resolved. If that fails resolution, then the name prep.ai.ai.mit.edu would be tried. If that fails resolution, then the name prep.ai.MIT.EDU would be tried.
 - A user enters ftp prep. The domain name prep.ai.mit.edu would try to be resolved. If that fails resolution, then the name prep.MIT.EDU would be tried. If that fails resolution, then the name prep would be tried.
- If the name specified by the user ends with a period (.), then both the NDOTS:*n* specification and the SEARCH values are ignored. For example, a user enters ftp prep.ai.. The domain name prep.ai. would try to be resolved. If that fails, no other name is tried.

Steps for modifying

You can refresh this statement using the MODIFY command. For more information about parameters used with the [MODIFY command](#) command, see [z/OS Communications Server: IP System Administrator's Commands](#).

Examples

The following statement sets NDOTS to 2:

```
OPTIONS NDOTS:2
```

The following statement by default set NDOTS to 1:

```
OPTIONS
```

Usage notes

- If the OPTIONS statement is not specified or specified without a NDOTS:*n* parameter, a value of :1 is assigned.

Guideline: This assumes only one OPTIONS statement in a single resolver configuration.

- If multiple OPTIONS NDOTS:*n* statements are encountered in a single resolver configuration file, the last statement takes effect.

[“SEARCH statement” on page 347](#)

[“Resolver configuration statements for IBM z/OS Container Platform environments” on page 343](#)

SEARCH statement

Use the SEARCH statement to specify the list of domain names that are appended, in the order listed, to the host name to form the fully qualified domain name of a host. A domain name is appended until either the list is exhausted, or an IP address is determined. The domain names are appended for name server queries as well as for searching the local host tables.

Syntax

Parameters

domain

The domain name is appended to the host name. This name usually has imbedded dots.

No case translation is performed on the domain name. Up to six names separated by at least one blank are allowed. If the domain names cannot fit on a single SEARCH statement, multiple SEARCH statements can be used. If more than six domain names are specified, only the first six are used.

Steps for modifying

You can refresh this statement using the MODIFY command. For more information about parameters used with the [MODIFY command](#) command, see [z/OS Communications Server: IP System Administrator's Commands](#).

Examples

The following example would establish a search list:

```
SEARCH test.cluster.com US.CLUSTER.COM cluster.com
```

An equivalent specification is:

```
SEARCH test.cluster.com
SEARCH US.CLUSTER.COM
SEARCH cluster.com
```

If a user entered FTP system1 and assuming that `OPTIONS NDOTS:n` (see [OPTIONS statement](#)) was specified such that the SEARCH domains should be appended, the following order of name queries would be done in sequence by the resolver until either an answer was found, or the list was exhausted:

1. system1.test.cluster.com
2. system1.US.CLUSTER.COM
3. system1.cluster.com

Related reference

[“OPTIONS NDOTS statement” on page 346](#)

[“Resolver configuration statements for IBM z/OS Container Platform environments” on page 343](#)

TCPIPJOBNAME statement

Use the TCPIPJOBNAME statement to specify the member name of the procedure used to start the TCP/IP address space.

Syntax

```
TCPIPJOBNAME tcpip_proc
```

Parameters

tcpip_proc

The name of the member in the cataloged procedure library that is used to start the TCP/IP address space. The maximum length of the start procedure is 8 characters

Examples

To specify TCPIPA as the name of the procedure that was used to start the TCP/IP address space, use the following code:

```
TCPIPJOBNAME TCPIPA
```

Usage notes

- You must specify the proper procedure name of the TCP/IP address space on your system. If `tcPIP_proc` is not the name of the started TCP/IP address space, applications using any TCP/IP provided API fail with an irrecoverable interaddress communication error.
- For more information about why the `TCPIPJOBNAME` parameter must match the name of the associated TCP/IP address space and be the same name as that defined for the corresponding `AF_INET` physical file system in the `BPXPRMxx` member used to configure z/OS UNIX, see [z/OS Communications Server: IP Configuration Guide](#).

HOSTS statement

Use the HOSTS statement in the Name Service Switch (NSSwitch) configuration file to specify the order in which the DNS or local files are to be used for host name resolution for IBM z/OS Container Platform environments.

Note: The z/OS UNIX file `/etc/nsswitch.conf` in the container's filesystem namespace (if it exists), is used as the NSSwitch configuration file.

Syntax

Parameters

DNS

The domain name servers specified by the `NAMESERVER` statement is used for name resolution. The `NAMESERVER` statement can be specified in the z/OS UNIX file `/etc/resolv.conf` in the container's filesystem namespace. For more information, see [“NAMESERVER statement” on page 344](#).

FILES

The local host file, `/etc/hosts` in the container's filesystem namespace (if it exists), is used for name resolution.

Steps for modifying

You can refresh this statement using the `MODIFY RESOLVER,REFRESH` command. For more information about parameters used with the `MODIFY` command, see [z/OS Communications Server: IP System Administrator's Commands](#).

Examples

In the following example, only the name servers are queried directly:

```
hosts: DNS
```

In the following example, only the local host tables are used:

```
hosts: FILES
```

In the following example, the local host tables are used first. If there is no resolution, then the name servers are queried directly.

```
hosts: FILES DNS
```

In the following example, the name servers are queried directly. If there is no resolution, then the local host tables are used next.

```
hosts: DNS FILES
```

Usage notes

- If a HOSTS statement is not specified, the domain name servers are queried first, and if the resolution request is not successful, the local host file, if it exists, is used.
- If an incorrect parameter value is specified, the entire HOSTS statement is ignored.
- The last syntactically correct HOSTS statement is used.

Chapter 6. z/OS Load Balancing Advisor and Load Balancing Agent

This topic contains the following information:

- [“General syntax rules for z/OS Load Balancing Advisor” on page 351](#)
- [“Starting the z/OS Load Balancing Advisor” on page 351](#)
- [“Load Balancing Advisor sample start procedure” on page 352](#)
- [“Load Balancing Advisor configuration file statements” on page 352](#)
- [“Starting the z/OS Load Balancing Agent” on page 362](#)
- [“z/OS Load Balancing Agent sample start procedure” on page 363](#)
- [“z/OS Load Balancing Agent configuration file statements” on page 363](#)

The z/OS Load Balancing Advisor communicates with outboard load balancers (LBs) and one or more z/OS Load Balancing Agents.

The purpose of the z/OS Load Balancing Advisor is to provide information to an outboard load balancer (such as a CISCO Content Switching Module [CSM]) about the availability of various resources (applications) and their relative ability to handle additional workload with respect to other resources that have the ability to handle the same workload. The outboard load balancer takes data the z/OS Load Balancing Advisor passes to it and makes a determination about where to route new workloads. This load balancing solution is different than existing load balancing solutions such as sysplex distributor. In this implementation, the actual decision of where to route work is made outside of the sysplex.

For additional [overview and configuration information about the Load Balancing Advisor](#), see [z/OS Communications Server: IP Configuration Guide](#).

General syntax rules for z/OS Load Balancing Advisor

The following list shows the general configuration rules for the z/OS Load Balancing Advisor:

- Each statement must have a corresponding value and be separated from its value by one or more blanks.
- Only one statement and its values can be specified per line.
- Text beyond the specified statement and values is ignored.
- Text beginning with the # is a comment and is ignored. The remainder of the line following the # is considered part of the comment.
- Statements should be specified only once. When a statement is repeated, a warning message is written to the syslogd file, and the last instance of the statement is used.
- Statements that contain braces ({ and }) must specify the braces on separate lines. For example:

```
agent_id_list
{
1.2.3.4..8000
10.10.10.0..9000
}
```

Starting the z/OS Load Balancing Advisor

You must start the Advisor from a start procedure. A sample start procedure is shipped in member EZBLBADV in SEZAINST. The Advisor must have a configuration file. A sample Advisor configuration file is shipped in member EZBLBADC in SEZAINST.

Load Balancing Advisor sample start procedure

This topic shows the advisor sample start procedure.

```
//LBADV      PROC
//*
//*  IBM Communications Server for z/OS
//*  SMP/E distribution name: EZBLBADV
//*
//*  Licensed Materials - Property of IBM
//*  5694-A01
//*  Copyright IBM Corp. 2005, 2009
//*  Status = CSV1R11
//*
//*  Function: Sample procedure for running the
//*           z/OS Load Balancing Advisor
//*
//LBADV EXEC PGM=EZBLBADV,REGION=0K,TIME=NOLIMIT,
// PARM='/'
//*
//*** Notes:
//*
//* - The system link list concatenation must contain the TCP/IP
//*   runtime libraries and the C runtime libraries. If they are
//*   not in the link list concatenation, this procedure will need
//*   to be changed to STEPLIB to them.
//*   If you add them to STEPLIB, they must be APF authorized.
//*
//* - The z/OS Load Balancing Advisor requires a configuration file
//*   which can be a member of an MVS PDS(E), an MVS sequential file,
//*   or a z/OS UNIX file.
//*
//CONFIG DD DSN=TCPIP.TCPPARMS(LBADVCNF),DISP=SHR
//*CONFIG DD DSN=TCPIP.CONFIG.LBADV,DISP=SHR
//*CONFIG DD PATH='/etc/lbadv.conf',PATHOPTS=(ORDONLY)
//STDENV DD DUMMY
//SYSPRINT DD SYSOUT=*,DCB=(RECFM=F,LRECL=80,BLKSIZE=80)

//SYSERR DD SYSOUT=*
//SYSOUT DD SYSOUT=*,DCB=(RECFM=F,LRECL=80,BLKSIZE=80)
//CEEDUMP DD SYSOUT=*,DCB=(RECFM=FB,LRECL=132,BLKSIZE=132)
//CEESNAP DD SYSOUT=*,DCB=(RECFM=FB,LRECL=132,BLKSIZE=132)
//SYSMDUMP DD DISP=SHR,DSN=your.data.set.name
```

Figure 8. Advisor sample start procedure

Load Balancing Advisor configuration file statements

Table 12 on page 352 lists the advisor configuration file statements.

Rule: You must specify at least one of the load balancer connection statements (lb_connection_v4 or lb_connection_v6). You can specify both statements.

Table 12. Advisor configuration file statements			
Configuration file statement	Default	Required or Optional	Purpose
agent_connection_port	No value is specified	Required	Specifies the port the Advisor should listen on for connections from Agents.
agent_id_list	No value is specified	Optional	Specifies which agents are allowed to connect to the Advisor.
debug_level	7	Optional	Specifies the level of debug information that is logged.

<i>Table 12. Advisor configuration file statements (continued)</i>			
Configuration file statement	Default	Required or Optional	Purpose
lb_connection_v4	No value is specified	Required (1)	Specifies the IPv4 address and port the Advisor should listen on for IPv4 connections from load balancers.
lb_connection_v6	No value is specified	Required (1)	Specifies the IPv6 address and port the Advisor should listen on for IPv6 connections from load balancers.
lb_id_list	No value is specified	Optional	Specifies which load balancers are allowed to connect to the Advisor.
port_list	No value is specified	Optional	Specifies a list of ports and the type of WLM recommendation that should be used for each.
sysplex_group_name	No value is specified	Optional	Specifies the TCP/IP sysplex group name for the subplex that this Advisor handles.
update_interval	60	Optional	Specifies how often agents update the Advisor with new information.
wlm	basewlm	Optional	Specifies the default type of WLM recommendation that should be used.

The connected arrows in Figure 9 on page 354 show configuration relationships relative to the Advisor. The IP address in the `advisor_id` statement can be any IP address belonging to the TCP/IP stack the Advisor is running on; however, this value should be a DVIPA.

Tip: The Agent `host_connection` statement and the corresponding entry in the Advisor `agent_id_list` are optional if AT-TLS is used for the connection between the Advisor and the Agent.

Syntax

➤ agent_id_list — { agent_ipaddr..agent_port } ➤

Parameters

agent_ipaddr..agent_port

Use *agent_ipaddr..agent_port* to specify a list of Agents that are allowed to connect to the Advisor. This parameter is required. The list consists of one or more blank-delimited IP address and port pairs each specified on a separate line, which are all contained within braces. There should be no spaces between the IP address, the two ellipses (..), and the port. These pairs represent the IP address and port of a given Agent.

There is no limit to the length of a line. The IP address can be an IPv4 or an IPv6 address. The IPv4 INADDR_ANY address (0.0.0.0) and the IPv6 unspecified address (::) are not allowed. If *agent_ipaddr..agent_port* is specified, this parameter must match the addresses specified in the host_connection configuration statement on the Agents.

The valid range of port values is 1 - 65 535.

Rule: You can specify only complete IP addresses. You cannot specify host names, prefixes, or subnets. Any given *agent_ipaddr..agent_port* pair must be specified on one line; it cannot be continued to a subsequent line.

debug_level statement

Use the debug_level statement to specify the level of debug information that is logged.

Syntax

➤ debug_level — *n* ➤

Parameters

n

Use *n* to specify the debug level. All log messages are written to syslogd. The value of *n* represents a particular debug level or combination of debug levels according to the following values:

0

None. No debug messages are logged.

1

Error-level messages are logged.

2

Warning-level messages are logged.

4

Event-level messages are logged.

8

Info-level messages are logged.

16

Message-level messages are logged. These are details of the messages (packets) sent between the Advisor and Load Balancer, and the Advisor. This level is intended for IBM service use only.

64

Debug-level messages are logged. These are internal debug messages intended for Development and Service. This level is intended for IBM service use only.

128

Trace-level messages are logged. These are function entry and exit traces that show the path through the code. This level is intended for IBM service use only.

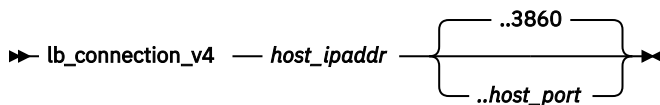

Guideline: To log a combination of debug levels, add the debug level numbers. The default debug level is 7, which captures all Error, Warning, and Event messages.

lb_connection_v4 statement

Use the `lb_connection_v4` statement to specify the IPv4 address and port the Advisor should listen on for IPv4 connections from load balancers.

This statement is optional. However, if neither an `lb_connection_v4` nor an `lb_connection_v6` statement is present in the configuration file, a terminating error results.

Syntax

Parameters

host_ipaddr..host_port

Use `host_ipaddr..host_port` to specify which IPv4 address and optionally the port the Advisor listens on for IPv4 connections from a load balancer. This address and port must be coordinated on any load balancers that wish to connect to this Advisor. The port is optional and defaults to 3860.

Rule: There should be no spaces between the IP address, the two ellipses (..), and the port. The `host_ipaddr..host_port` pair must be specified on one line. It cannot be continued to a subsequent line.

The valid range of port values is 1 - 65 535.

Guideline: This address should be a DVIPA.

Restriction: If the host where the Advisor is running has only a single interface IP address, do not specify the same port on the `agent_connection_port` and `lb_connection_v4` or `lb_connection_v6` statements. Having only a single IP address means both the z/OS Load Balancer and the Agent would need to be configured with that address, and both would end up connecting to the Advisor's socket for z/OS Load Balancer connections.

lb_connection_v6 statement

Use the `lb_connection_v6` statement to specify the IPv6 address and port the Advisor should listen on for IPv6 connections from load balancers.

This statement is optional. However, if neither an `lb_connection_v4` nor an `lb_connection_v6` statement is present in the configuration file, a terminating error results.

Syntax

Parameters

host_ipaddr..host_port

Use *host_ipaddr..host_port* to specify which IPv6 address and optionally the port the Advisor listens on for IPv6 connections from a load balancer. This address and port must be coordinated on any load balancers that wish to connect to this Advisor. The port is optional and defaults to 3860.

Rule: There should be no spaces between the IP address, the two ellipses (..) and the port. The *host_ipaddr..host_port* pair must be specified on one line. It cannot be continued to a subsequent line.

The valid range of port values is 1 - 65 535.

Guideline: For higher availability, specify a unique application-instance DVIPA.

Restrictions:

- If the host where the Advisor is running has only a single interface IP address, do not specify the same port on the *agent_connection_port* and *lb_connection_v4* or *lb_connection_v6* statements. Having only a single IP address means both the z/OS Load Balancer and the Agent would need to be configured with that address, and both would end up connecting to the Advisor's socket for z/OS Load Balancer connections.
- In general, most IPv6 listening sockets accept IPv4 connections if the listening socket is using the IPv6 unspecified address (:::). However, for this listening socket, only IPv6 connections are accepted, even if you use the IPv6 unspecified address. If you expect to receive IPv4 connections from load balancers, you must specify the *lb_connection_v4* statement.

lb_id_list statement

Use the *lb_id_list* statement to specify which load balancers are allowed to connect to the Advisor.

Rules:

- If you are using AT-TLS with SERVAUTH access control checks to validate all connections between Advisor-load balancer and Advisor-ADNR, this statement is optional. If you specify this statement, but AT-TLS is used for the connection, this statement is ignored. If this statement is not specified, AT-TLS is required and the security checks must succeed.
- If you are not using AT-TLS with SERVAUTH access control checks to validate all Advisor-load balancer connections and Advisor-ADNR connections, this statement is required or the connection is refused.

Syntax

►► *lb_id_list* — Place Braces and Parameters on Separate Lines ►►

Place Braces and Parameters on Separate Lines

Parameters

lb_ipaddr

Specifies the load balancers that are allowed to connect to the Advisor. The list consists of one or more blank-delimited IP addresses, each specified on a separate line. All IP addresses are contained in one set of braces. These addresses represent the IP address of a given load balancer. There is no limit to the length of a line.

Rules:

- You can specify only complete IP addresses. You cannot specify host names, prefixes, or subnets. Any IP address parameter on this statement must be specified on one line; it cannot be continued to a subsequent line.
- If you specify at least one IPv4 address, you must specify an `lb_connection_v4` statement. Similarly, if you specify at least one IPv6 address, you must specify an `lb_connection_v6` statement.

Guideline: If the load balancer has multiple source IP addresses that it can use, ensure that the `lb_id_list` statement contains the address that the load balancer should use as a source IP address when connecting as a client to the Advisor.

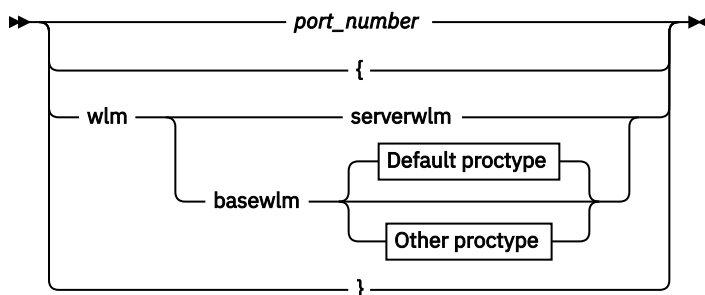

port_list statement

Use the `port_list` statement to specify a list of ports and the type of Workload Manager (WLM) recommendation that should be used for each.

Syntax

port_definition

Default proctype

Other proctype

Guideline: Place brackets and parameters on separate lines.

Parameters

port_number

A numerical value that represents a valid port number. Keywords on the remainder of this statement are applied to all members that match this port number.

wlm

A keyword that is used to override the default WLM recommendation method that is specified or made the default by the *wlm* statement. See [z/OS Communications Server: IP Configuration Guide](#) for more information about WLM recommendation types. .

basewlm

Specifies that WLM system weight recommendations are being used for determining the best candidates for workload balancing for all members with ports that match the *port_number* value.

proctype

For workloads that use server-specific WLM weights, WLM typically returns a composite raw weight that takes into consideration how well the server is meeting its WLM goals with respect to the various types of processors the server is using.

For workloads that use WLM system weight recommendations, WLM is unaware of how a resource is using the various processors. Instead, WLM returns a weight for each processor type that is based on the amount of displaceable capacity for this processor in this system as compared to the available capacity for this processor on the other target systems.

For applications that use specialty processors and receive WLM system weight recommendations, specify the *proctype* parameter to indicate the expected proportion of each type of processor that the target application's workloads should use. A composite recommendation is determined from these proportions. Express each of the proportions as a number in the range 0 - 99. Each proportion value is divided by the total to determine the processor usage pattern; see the example that follows. To determine the processor proportions to configure, study your workload usage of assist processors by analyzing SMF records, using performance monitors reports, such as RMF, and so on.

For example, the *proctype* value CP 5 zAAP 0 zIIP 3 specifies a processor usage pattern such that 5/8 of the application's processor uses conventional processors (CP), and 3/8 of the application's CPU utilization uses zIIP processors.

For example, PROCTYPE CP 60 ZAAP 30 ZIIP 10, specifies a CPU usage pattern such that 60% uses conventional processors (CP), 30% uses zAAP processors, and 10% uses zIIP processors.

zAAPs and zIIPs are specialty processors designed to offload specific application workloads. Some target applications can take advantage of these specialty processors. For workloads that use server-specific WLM weights, WLM typically returns a composite raw weight that takes into consideration how well the server is meeting its WLM goals with respect to the various types of processors the server is using. For workloads that use the system-wide WLM

recommendation, WLM is unaware of how a resource is using the various processors. Instead, WLM returns a weight for each processor type that is based on the amount of displaceable capacity for this processor in the system as compared to the available capacity for this processor on the other target systems.

Possible values are:

CP *x*

The proportion of the workload that uses conventional processors.

zAAP *y*

The proportion of the workload that uses zAAP processors.

zIIP *z*

The proportion of the workload that uses zIIP processors.

Requirement: If you specify a *proctype* value, it must be followed by braces (each brace on a separate line and each processor type and its value on a separate line). Each processor type parameter is optional; however, at least one processor type and its value must be coded. Each processor type can be specified in any order. When specified, each processor type must be specified with a value. Each processor type parameter and its value must be specified on separate lines.

Restrictions: When processor types are specified, at least one type must be specified with a nonzero value.

When you specify a *proctype* value on this statement, all *proctype* values on WLM statements are overridden. If you do not specify a processor type, the value 0 is assumed for that processor type.

serverwlm

Specifies that server-specific WLM recommendations are the WLM recommendation method to be used for determining the best candidates for workload balancing for all members with ports matching the *port_number* value. The actual WLM recommendation method used can be different than the configured method, depending on whether if each system reporting on members of the group supports server-specific WLM recommendations.

sysplex_group_name statement

Use the *sysplex_group_name* statement to specify the TCP/IP sysplex group name for the subplex that this Advisor handles when operating the Load Balancing Advisor in a sysplex subplexing environment.

You should specify a *sysplex_group_name* statement in the configuration file of each Load Balancing Advisor that is operating in a sysplex subplexing environment. The statement is optional. If the statement is omitted, it is assumed that the Advisor is not running in a subplexing environment.

Syntax

➤ *sysplex_group_name* — EZBT*vvtt* ➤

Parameters

EZBT*vvtt*

Specify the TCP/IP sysplex group name that is associated with the subplex that this Advisor handles. The TCP/IP sysplex group name is in the format EZBT*vvtt*. The *vv* value is the VTAM subplex group ID, as specified on the VTAM XCFGRPID start option. The *tt* value is the TCP/IP subplex group ID, as specified on the XCFGRPID parameter of the GLOBALCONFIG statement in the TCP/IP profile. If you did not specify the VTAM XCFGRPID start option when VTAM was started, then *vv* is CP. If you did not specify the XCFGRPID parameter on the GLOBALCONFIG statement in the TCP/IP profile, then *tt* is CS.

Tip: Use the DISPLAY TCPIP,,SYSPLEX,GROUP command to display the current TCP/IP sysplex group name.

update_interval statement

Use the update_interval statement to specify how often agents update the Advisor with new information.

Syntax

➔ update_interval — *n* ➔

Parameters

n

Use *n* to specify the update interval in seconds, which determines how frequently Agents update the Advisor with information. *n* must be an integer in the range of 10 - 600 (10 seconds to 10 minutes). This statement is optional. The default is 60 seconds.

wlm statement

Use the wlm statement to specify the default Workload Manager (WLM) recommendation method that is used for each member, unless overridden on a per-port basis by the port_list statement. For more details about WLM recommendation types, see [Customizing optional statements in z/OS Communications Server: IP Configuration Guide](#).

This statement is optional, and the default is basewlm.

Syntax

Parameters

basewlm

Specifies that WLM system weight recommendations should be used to determine the best candidates for workload balancing.

proctype

For workloads that use server-specific WLM weights, WLM typically returns a composite raw weight that takes into consideration how well the server is meeting its WLM goals with respect to the various types of processors the server is using.

For workloads that use WLM system weight recommendations, WLM is unaware of how a resource is using the various processors. Instead, WLM returns a weight for each processor type that is based on the amount of displaceable capacity for this processor in this system as compared to the available capacity for this processor on the other target systems.

For applications that use specialty processors and receive WLM system weight recommendations, specify the *proctype* parameter to indicate the expected proportion of each type of processor that the target application's workloads should use. A composite recommendation is determined from these proportions. Express each of the proportions as a number in the range 0 - 99. Each

proportion value is divided by the total to determine the processor usage pattern; see the example that follows. To determine the processor proportions to configure, study your workload usage of assist processors by analyzing SMF records, using performance monitors reports, such as RMF, and so on.

For example, the *proctype* value CP 5 zAAP 0 zIIP 3 specifies a processor usage pattern such that 5/8 of the application's processor uses conventional processors (CP), and 3/8 of the application's processor uses zIIP processors.

zAAPs and zIIPs are specialty processors designed to offload specific application workloads. Some target applications can take advantage of these specialty processors. For workloads that use server-specific WLM weights, WLM typically returns a composite raw weight that takes into consideration how well the server is meeting its WLM goals with respect to the various types of processors the server is using. For workloads that use the system-wide WLM recommendation, WLM is unaware of how a resource is using the various processors. Instead, WLM returns a weight for each processor type that is based on the amount of displaceable capacity for this processor in the system as compared to the available capacity for this processor on the other target systems.

Possible values are:

CP x

The proportion of the workload that uses conventional processors.

zAAP y

The proportion of the workload that uses zAAP processors.

zIIP z

The proportion of the workload that uses zIIP processors.

Requirement: If you specify a *proctype* value, it must be followed by braces (each brace on a separate line and each processor type and its value on a separate line). Each processor type parameter is optional; however, at least one processor type and its value must be coded. Each processor type can be specified in any order. When specified, each processor type must be specified with a value. Each processor type parameter and its value must be specified on separate lines.

Restrictions: When processor types are specified, at least one type must be specified with a nonzero value.

When you specify a *proctype* value on this statement, all *proctype* values on WLM statements are overridden. If you do not specify a processor type, the value 0 is assumed for that processor type.

serverwlm

Specifies that server-specific WLM recommendations should be used to determine the best candidates for workload balancing. The actual WLM recommendation method used can be different than the configured method, depending whether each system that reports on members of the group supports server-specific WLM recommendations.

Result: zAAP and zIIP processor capacity is automatically included when the SERVERWLM parameter is specified and all systems in the sysplex are V1R9 or later.

Starting the z/OS Load Balancing Agent

Rule: You must start the Agent from a start procedure.

A sample start procedure is shipped in member EZBLBAGE in SEZAINST. A configuration file is required. A sample Agent configuration file is shipped in member EZBLBAGC in SEZAINST.

z/OS Load Balancing Agent sample start procedure

```
//LBAGENT PROC
//*
//* IBM Communications Server for z/OS
//* SMP/E distribution name: EZBLBAGE
//*
//* Licensed Materials - Property of IBM
//* 5694-A01
//* Copyright IBM Corp. 2005, 2009
//* Status = CSV1R11
//*
//* Function: Sample procedure for running the
//* z/OS Load Balancing Agent
//*
//LBAGENT EXEC PGM=EZBLBAGE,REGION=0K,TIME=NOLIMIT,
// PARM='/'
//*
//*** Notes:
//*
//* - The system link list concatenation must contain the TCP/IP
//* runtime libraries and the C runtime libraries. If they are
//* not in the link list concatenation, this procedure will need
//* to be changed to STEPLIB to them.
//* If you add them to STEPLIB, they must be APF authorized.
//*
//* - The z/OS Load Balancing Agent requires a configuration file
//* which can be a member of an MVS PDS(E), an MVS sequential file,

Figure 10. Agent sample start procedure

z/OS Load Balancing Agent configuration file statements

Table 13 on page 363 lists the agent configuration file statements.

Table 13. Agent configuration file statements			
Configuration file statement	Default	Required or Optional	Purpose
advisor_id	No value is specified	Required	Specifies the IP address and port of the Advisor that this Agent communicates with.
debug_level	7	Optional	Specifies the level of debug information that is logged.
host_connection	No value is specified	Optional	Specifies the local IP address and port that the Agent binds to for communications with the Advisor.

Table 13. Agent configuration file statements (continued)

Configuration file statement	Default	Required or Optional	Purpose
sysplex_group_name	No value is specified	Optional	Specifies the TCP/IP sysplex group name for the subplex that this Agent handles.

advisor_id statement

Use the `advisor_id` statement to specify the IP address and port of the Advisor that this Agent communicates with.

Syntax

➤ `advisor_id` — *advisor_ipaddr.advisor_port* ➤

Parameters

advisor_ipaddr.advisor_port

Use *advisor_ipaddr.advisor_port* to specify the IP address and the port of the Advisor that this agent communicates with. Both the IP address and the port are required. The port must match the port specified in the Advisor's `agent_connection_port` configuration statement. The two ellipses (..) must immediately follow the *advisor_ipaddr* without any intervening spaces, and the port number must immediately follow the ellipses, without any intervening spaces. The IP address can be an IPv4 or an IPv6 address. The valid range of port values is 1 - 65 535.

Guideline: This address should be a VIPA.

Rule: If you specify an IPv4 address for `advisor_id` and you specify `host_connection`, you must specify an IPv4 address in the `host_connection` statement. Similarly, if you specify an IPv6 address for `advisor_id` and you specify `host_connection`, you must specify an IPv6 address in the `host_connection` statement.

debug_level statement

Use the `debug_level` statement to specify the level of debug information that is logged.

Syntax

➤ `debug_level` — *n* ➤

Parameters

n

Use *n* to specify the debug level. All log messages are written to syslogd. The value of *n* represents a particular debug level or combination of debug levels according to the following values:

0

None. No debug messages are logged.

1

Error-level messages are logged.

- 2** Warning-level messages are logged.
- 4** Event-level messages are logged.
- 8** Info-level messages are logged.
- 16** Message-level messages are logged. These are details of the messages (packets) sent between the Advisor and Load Balancer, and the Advisor. This level is intended for IBM service use only.
- 32** Collection-level messages are logged. These are details of the collection and manipulation of data supporting the calculated weights. This level is intended for IBM service use only.
- 64** Debug-level messages are logged. This level is intended for IBM service use only.
- 128** Trace-level messages are logged. These are function entry and exit traces that show the path through the code. This level is intended for IBM service use only.
- Guideline:** To log a combination of debug levels, add the debug level numbers. The default debug level is 7, which captures all Error, Warning, and Event messages.

host_connection statement

Use the `host_connection` statement to specify the local IP address and port that the Agent binds to for communications with the Advisor.

Rules:

- If you are using AT-TLS with SERVAUTH access control checks to validate the Advisor-Agent connection, this statement is optional. If you specify this statement, but AT-TLS with SERVAUTH access control checks is used for the connection, the Advisor does not verify that the *host_ipaddr* and *host_port* specified on this statement is in its *agent_id_list* statement. If you omit this statement, AT-TLS with SERVAUTH access control checks is required, and the security checks must succeed.
- If you are not using AT-TLS with SERVAUTH access control checks to validate the Advisor-Agent connection, this statement is required, and the address and port must match one of the IP address and port pairs that are specified in the Advisor's *agent_id_list* configuration statement.
- If you specify this statement, the Agent binds to the specified IP address and port.

Syntax

➡ `host_connection` — *host_ipaddr..host_port* ➡

Parameters

host_ipaddr..host_port

Specifies the local IP address and the port that this Agent binds to. Both the IP address and the port are required. The two ellipses (..) must immediately follow the *host_ipaddr* value without any intervening spaces, and the port number must immediately follow the ellipses (..) without any intervening spaces. The IP address can be an IPv4 or an IPv6 address.

The valid range of port values is 1 - 65 535.

Rules:

- If you specify an IPv4 address, you must specify an IPv4 address in the `advisor_id` statement. Similarly, if you specify an IPv6 address, you must specify an IPv6 address in the `advisor_id` statement.
- In a subplexing environment, the address specified on the `host_connection` statement must be configured and owned by a stack in the same subplex as the Load Balancing Agent. If there is more than one TCP/IP stack on this system, in this subplex, the IP address must be a DVIPA defined in a `VIPARANGE` statement on each of these TCP/IP stacks so that the Agent can connect without regard to the order in which the TCP/IP stacks on this system are started.

sysplex_group_name statement

Use the `sysplex_group_name` statement to specify the TCP/IP sysplex group name for the subplex that this Agent handles when operating the Load Balancing Agent in a sysplex subplexing environment.

You should specify the `sysplex_group_name` statement in the configuration file of each Load Balancing Agent operating in a sysplex subplexing environment. The statement is optional. If the statement is omitted, it is assumed that the Agent is not running in a subplexing environment

Tip: Use the `DISPLAY TCPIP,,SYSPLEX,GROUP` command to display the current TCP/IP sysplex group name.

Syntax

➤ `sysplex_group_name` — `EZBTvvtt` ➤

Parameters

EZBTvvtt

Specify the TCP/IP sysplex group name that is associated with the subplex that this Agent handles. The TCP/IP sysplex group name is in the format `EZBTvvtt`. The `vv` value is the VTAM subplex group ID, as specified on the `VTAM XCFGRPID` start option. The `tt` value is the TCP/IP subplex group ID, as specified on the `XCFGRPID` parameter of the `GLOBALCONFIG` statement in the TCP/IP profile. If you did not specify the `VTAM XCFGRPID` start option when VTAM was started, then `vv` is CP. If you did not specify the `XCFGRPID` parameter on the `GLOBALCONFIG` statement, then `tt` is CS.

Chapter 7. Automated domain name registration

The automated domain name registration (ADNR) application is a function that dynamically updates name servers with information about sysplex resources in near real time. The DNS names managed by ADNR can be names that represent all instances of an application within the sysplex, names that represent a specific instance of an application within the sysplex, names that represent the entire sysplex, as well as names that represent individual systems within the sysplex.

This topic contains the following information:

- [“Starting the automated domain name registration application” on page 368](#)
- [“General configuration rules for automated domain name registration” on page 367](#)
- [“EZBADNRS sample start procedure for automated domain name registration application” on page 368](#)
- [“Automated domain name registration application configuration file ” on page 369](#)

For additional overview and configuration information about [automated domain name registration](#), see [z/OS Communications Server: IP Configuration Guide](#).

General configuration rules for automated domain name registration

The following list shows the general configuration rules for the automated domain name registration application (ADNR):

- Each statement must have a corresponding value and be separated from its value by one or more blanks.
- Only one statement and its values can be specified per line.
- Text beyond the specified statement and values is ignored.
- Statements that contain braces ({ and }) must specify the braces on separate lines. For example:

```
DNS mydns1
{
  dns_id 10.11.12.0..553
  zone zone1
  {
    domain_suffix myplex1.mycorp.com
    transfer_key transfer_key1
    update_key update_key1
  }
  zone zone2
  {
    domain_suffix myplex2.mycorp.com
    transfer_key transfer_key2
    update_key update_key2
    ttl 15
  }
}
```

- Any text beyond an opening or closing brace is ignored.
- Text beginning with a # is a comment and is ignored. The remainder of the line following the # is considered part of the comment.
- A uuid statement, gwm statement, and at least one dns statement are required.
- For statements with identical labels, a warning message is written to the log, and the last instance of the statement is used.
- As a statement is processed, all of the parameters are examined. Any parameter that is specified incorrectly causes an error. Any inconsistencies between parameters also cause an error. For example, using an IPv4 address for the local endpoint and an IPv6 address as a remote endpoint causes an error.

- Inconsistencies between statements cause errors. For example, some statements reference other statements. Statement order is not important, but if after processing the entire file if all references are not resolved (such as a dns statement referencing a key statement that is not present), an error results.
- When generating resource records (RRs), more than one group statement can refer to the same dns statement and zone parameter. However, each of the resource records generated for a zone must be a unique combination of *member_name* and *ipaddress* values. The name created when registering with a DNS server must be less than 255 characters. See the complete rules for name creation in the zone parameter in “dns statement” on page 373.
- A maximum of 100 zones is supported. If the file contains more than 100 zone statements, this causes an error.
- Files specified in any statements are opened and read to verify the existence of the file, and to verify that the correct permissions are in place to properly access the file.

Starting the automated domain name registration application

Rule: You must start the automated domain name registration (ADNR) application from a start procedure.

A sample start procedure is shipped in member ADNRS in SEZAINST. The ADNR application must have a configuration file. A sample configuration file is shipped in member ADNRC in SEZAINST.

EZBADNRS sample start procedure for automated domain name registration application

This topic shows a sample EZBADNRS start procedure.

```

//ADNR      PROC
//*
//*  IBM Communications Server for z/OS
//*  SMP/E distribution name: EZBADNRS
//*
//*  Licensed Materials - Property of IBM
//*  5694-A01
//*  Copyright IBM Corp. 2006,2009
//*  Status = CSV1R11
//*
//*  Function: Sample procedure for running the
//*            Automated Domain Name Registration application
//*
//ADNR      EXEC PGM=EZBADNR,REGION=0K,TIME=NOLIMIT,
//  PARM='/'
//*
//* To start ADNR with stack affinity:
//*ADNR      EXEC PGM=EZBADNR,REGION=0K,TIME=NOLIMIT,
//*  PARM=('ENVAR("_BPXK_SETIBMOPT_TRANSPORT=TCPCS4")/')
//*
//*** Notes:
//*
//* - The system link list concatenation must contain the TCP/IP
//*   runtime libraries and the C runtime libraries. If they are
//*   not in the link list concatenation, this procedure will need
//*   to be changed to STEPLIB to them.
//*   If you add them to STEPLIB, they must be APF authorized.
//*
//* - The Automated Domain Name Registration requires a configuration
//*   file which can be a member of an MVS PDS(E), an MVS sequential
//*   dataset, or a z/OS UNIX file.
//*
//CONFIG    DD DSN=TCPIP.TCPPARMS(ADNRCNF),DISP=SHR
//*CONFIG    DD DSN=TCPIP.CONFIG.ADNR,DISP=SHR
//*CONFIG    DD PATH='/etc/adnr.conf',PATHOPTS=(ORDONLY)
//STDENV    DD DUMMY
//SYSPRINT  DD SYSOUT=*,DCB=(RECFM=F,LRECL=132,BLKSIZE=132)
//SYSIN     DD DUMMY
//SYSERR    DD SYSOUT=*
//SYSOUT    DD SYSOUT=*,DCB=(RECFM=F,LRECL=132,BLKSIZE=132)
//CEEDUMP   DD SYSOUT=*,DCB=(RECFM=FB,LRECL=132,BLKSIZE=132)
//CEESNAP   DD SYSOUT=*,DCB=(RECFM=FB,LRECL=132,BLKSIZE=132)
//SYSMDUMP  DD DISP=SHR,DSN=your.data.set.name

```

Figure 11. EZBADNR start procedure

Automated domain name registration application configuration file

Table 14 on page 369 lists the automated domain name registration application configuration file statements.

Table 14. Automated domain name registration application configuration (ADNR) file statements				
Configuration file statement	Default	Default Required or Optional	Purpose	See
arm_element_suffix	none	Optional	Specifies the suffix added to the default element name for the automatic restart manager (ARM).	“arm_element_suffix statement” on page 371
debug_level	7	Optional	Specifies the level of debug information that is logged.	“debug_level statement” on page 372

Table 14. Automated domain name registration application configuration (ADNR) file statements (continued)

Configuration file statement	Default	Default Required or Optional	Purpose	See
dns	none	Required (1)	Specifies a DNS server that supports dynamic DNS registration.	“dns statement” on page 373
gwm	none	Required (2)	Specifies the Global Workload Manager (GWM) that advises the ADNR application.	“gwm statement” on page 375
host_group	none	Optional	Specifies the set of IP addresses to register for a group of hosts.	“host_group statement” on page 376
ipaddrlist	none	Optional (3)	Specifies a list of IP addresses being referenced from the host_group or server_group statements.	“ipaddrlist statement” on page 378
key	none	Optional	Specifies the key to use when signing a dynamic DNS update or zone transfer.	“key statement” on page 378
server_group	none	Optional	Specifies the set of IP addresses to register for a group of servers.	“server_group statement” on page 379
uuid	none	Required	Identifies this automated domain name registration application instance and distinguishes it from all other automated domain name registration application instances, as well as from all other external load balancers using SASP.	“uuid statement” on page 380

Table 14. Automated domain name registration application configuration (ADNR) file statements
(continued)

Configuration file statement	Default	Default Required or Optional	Purpose	See
Notes: <ol style="list-style-type: none"> 1. At least one dns statement is required. 2. Only the last gwm statement in the configuration file is used. 3. Required if either a host_group or server_group statement is specified. 				

Rule: If the configuration file has been changed any time after ADNR has been initially started, you must issue a MODIFY <proc_name> REFRESH command before ADNR is stopped.

The connected arrows in Figure 12 on page 371 show configuration relationships relative to the z/OS Load Balancing Advisor (LBA) Advisor application. The IP address in the *gwm_id* parameter can be any IP address belonging to the TCP/IP stack that the Advisor is running on; however, this value should be a dynamic VIPA (DVIPA). The IP address in the *host_connection_addr* parameter can be any IP address belonging to the TCP/IP stack that the automated domain name registration application is running on; this value should also be a DVIPA.

Tip: ADNR's *host_connection_addr* parameter and the corresponding entry in the Advisor's *lb_id_list* are optional if AT-TLS is used for the connection between the Advisor and ADNR.

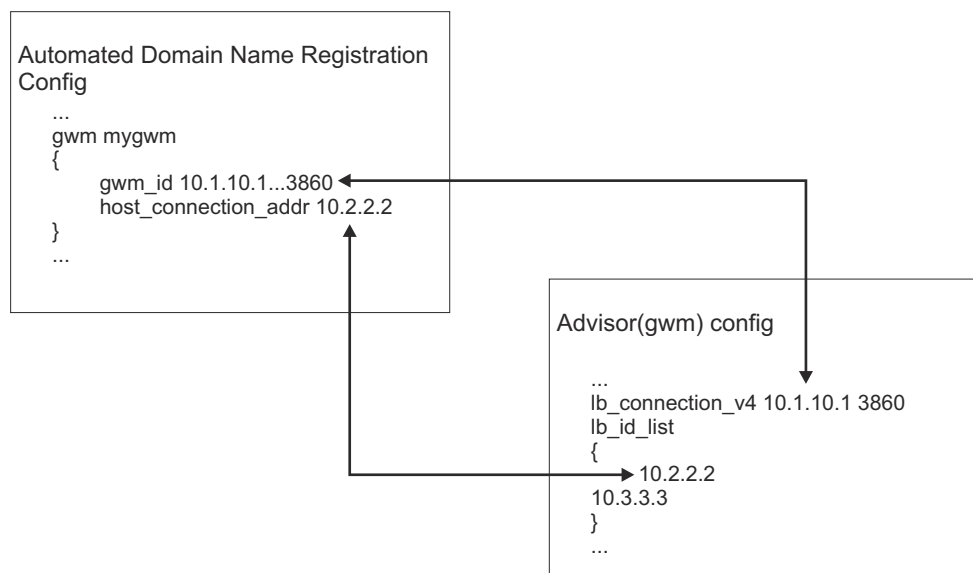

Figure 12. Configuration Relationships

arm_element_suffix statement

Use the *arm_element_suffix* statement to specify the suffix added to EZBADNR for the automatic restart manager (ARM) element name. This statement is optional.

Syntax

➤ arm_element_suffix — name ➤

Parameters

name

The `arm_element_suffix` value is an EBCDIC string 1 - 8 characters in length. The following characters are valid:

- Uppercase alpha characters
- Numeric characters (0 - 9)
- \$, #, @, and underscore (_)

Rules:

- The name should be unique across the sysplex.
- Do not enclose the string in quotation marks.

Restriction: The number symbol (#) is not allowed as the first character of name.

debug_level statement

Use the `debug_level` statement to specify the type and quantity of logging information to be written to the log file.

Syntax

Parameters

n

Used to specify the debug level. All log messages are written to syslogd. The value of *n* represents a particular debug level or combination of debug levels according to the values shown in [Table 15 on page 372](#).

To log a combination of debug levels, add together the debug level numbers. If a debug level value is not specified, the default debug level is 7, which captures all ERROR, WARNING, and EVENT messages.

[Table 15 on page 372](#) lists the possible values:

Table 15. debug_level values		
Debug level	Logging level	Description
0	None	No messages of any kind are sent to the logging file after initialization is complete.
1	ERROR	Error messages indicate that something requires attention. Messages at this level can be fatal (terminating) or can indicate that an important part of the automated domain name registration application is not working properly. This information is logged at the syslogd ERROR priority level.

Table 15. <i>debug_level</i> values (continued)		
Debug level	Logging level	Description
2	WARNING	Warning messages indicate that an error has occurred, but it is not severe enough to warrant an ERROR level. Corrective action might be necessary because the automated domain name registration application might not be functioning as intended. This information is logged at the syslogd WARNING priority level.
4	EVENT	Event messages are logged for events that occur periodically, like operator commands, UNIX signals, timer pops, receipt of a network message, and so on. This information is logged at the syslogd NOTICE priority level.
8	INFO	Informational messages are sent to the logging file. These messages do not require corrective action. This information is logged at the syslogd INFO priority level.
16	MESSAGE	Messages about the detailed contents of message packets that are sent between the GWM (Advisor) and the automated domain name registration application. Use these messages to assist debugging automated domain name registration application communications. This information is logged at the syslogd DEBUG priority level.
32	COLLECTION	Collection messages concern the details of managing the data in the DNS zones. This information is logged at the syslogd DEBUG priority level.
64	DEBUG	Debug messages are intended for Development or Service and give detail that customers do not normally want. The intention of this level of message is to provide information that is useful in debugging code, logic, or timing errors. This information is logged at the syslogd DEBUG priority level.
128	TRACE	Trace messages are intended for Development or Service to track code processing (footprints). This information is logged at the syslogd DEBUG priority level.

dns statement

Use the `dns` statement to define a DNS server that supports dynamic DNS update. The automated domain name registration application update-adds and update-deletes host names and IP addresses with the DNS server.

Requirement: This statement is required.

Syntax

➤ dns — *dns_label* — Put Braces and Parameters on Separate Lines ➤

Put Braces and Parameters on Separate Lines

zone

Parameters

dns

The keyword that defines the beginning of the dns statement.

dns_label

A string 1 - 32 characters in length for the label of this DNS server. This value is referenced from other statements in the automated domain name registration application configuration file and from automated domain name registration commands.

dns_id dns_addr..dns_port

Used to specify the IP address and port this DNS server is listening on. The port is optional; the default value is 53.

The valid range of port values is 1 - 65 535.

Rules:

- Do not put any spaces between the IP address, the two ellipses (..), and the port.
- The *dns_addr..dns_port* value must be specified on one line. It cannot be continued to a subsequent line.

zone

The keyword that defines the beginning of a zone owned by this DNS server.

zone_label

A string 1 - 32 characters in length for the label that specifies the name of the zone for which the DNS server is authoritative. This value is referenced from other statements in the automated domain name registration application configuration file and from automated domain name registration commands.

Restriction: Within the configuration file, all zone labels must be unique.

domain_suffix domain_suffix

The domain suffix of a zone for which the DNS server is authoritative.

Rules:

- All domain suffixes must be unique within a dns statement.
- The domain suffix cannot contain two consecutive periods together.

When the *domain_suffix* value is created, a trailing period is added if one was not configured.

All dynamic DNS updates sent to the DNS server have the domain suffix appended. Thus, the following names can be created by the automated domain name registration application. The longest of these names must be less than or equal to 255 characters in length, including the trailing period. For example:

```
host_group_name.domain_suffix.
host_name.domain_suffix.
server_group_name.domain_suffix.
server_name.server_group_name.domain_suffix.
```

update_key key_label

The label referencing the key statement that represents the key used in signing update-add and update-delete requests sent to this DNS server. If the update_key parameter is not specified, meaning transaction signature (TSIG) is not being used, then the update-add and update-delete requests are not signed.

transfer_key key_label

The label referencing the key statement that represents the key used in signing zone transfer requests sent to this DNS server. If the transfer_key parameter is not specified, meaning transaction signatures (TSIG) is not being used, then the zone transfer requests are not signed.

ttl

The time to live (TTL) value used for domain names registered with this zone. This indicates the amount of time, in seconds, that a DNS record exists in the cache of a non-authoritative name server or resolver before expiring from the cache. If the ttl parameter is not specified, the TTL is the value specified on the Load Balancing Advisor (LBA) *update_interval* configuration parameter. For information about the update interval of the LBA, see [“Load Balancing Advisor configuration file statements” on page 352](#).

The time to live of the resource record (RR) field is a 32-bit integer value, in seconds, and is primarily used by resolvers and non-authoritative name servers when they cache RRs. The TTL specifies how long an RR can be cached before it should be discarded.

The valid range of ttl values is 0 - 2 147 483 647 seconds.

gwm statement

Use the gwm statement to define a Global Workload Manager (GWM) that advises the automated domain name registration application.

The z/OS Load Balancing Advisor—Advisor application is an instance of a GWM.

Requirement: This statement is required.

Restriction: Only the last gwm statement in the automated domain name registration application configuration file is used.

Syntax

➤ gwm — gwm_label — Put Braces and Parameters on Separate Lines ➤

Put Braces and Parameters on Separate Lines

➤ { — gwm_id — gwm_addr —
 ..3860
 ┌──────────┐
 │ │
 └──────────┘
 ..gwm_port
 — host_connection_addr ip_addr — } ➤

Parameters

gwm

The keyword that defines the beginning of the gwm statement.

gwm_label

A string 1 - 32 characters in length for the label of the GWM that is communicating with the automated domain name registration application. This value is not referenced from other statements in the automated domain name registration application configuration file or from automated domain name registration commands.

gwm_id gwm_addr..gwm_port

The remote IP address and port that the GWM is listening on for connections from load balancers. The port is optional; the default value is 3860.

The valid range of port values is 1 - 65 535.

Tip: For higher availability, specify a unique application instance DVIPA for the remote IP address.

Rule: There should be no spaces between the IP address, the two ellipses (..), and the port. The *gwm_addr..gwm_port* value must be specified on one line. It cannot be continued to a subsequent line.

host_connection_addr ipaddr

The local IP address that the automated domain name registration application uses when creating the socket that is used to connect to the GWM if AT-TLS is not used.

Rules:

- If you are using AT-TLS with SERVAUTH access control checks to validate the Advisor-ADNR connection, this statement is optional. If you specify the *host_connection_addr* statement and use AT-TLS with SERVAUTH access control checks for the connection, the Advisor does not verify that the *host_connection_addr* statement is in its *lb_id_list* statement. If you omit this statement, AT-TLS with SERVAUTH access control checks is required, and the security checks must succeed.
- If you are not using AT-TLS with SERVAUTH access control checks to validate the Advisor-ADNR connection, this parameter is required and the IP address must match one of the IP addresses specified in the Advisor's *lb_id_list* configuration statement.
- If this parameter is specified, ADNR binds to the specified IP address.

Tip: For increased availability, specify a unique application-instance DVIPA for the local IP address.

host_group statement

Use the *host_group* statement to identify the set of IP addresses to update for a group of hosts. The automated domain name registration application updates the name server with the intersection between the IP addresses configured to the automated domain name registration application and the IP addresses active on the hosts in the sysplex.

The DNS names dynamically added to the name server take the form *host_group_name.domain_suffix*, where the *host_group_name* value is the name of the group of hosts being registered to the GWM and the *domain_suffix* value is the domain suffix name specified in a zone parameter on a *dns* statement.

The automated domain name registration application can also update individual host instances with the DNS server using the member keyword. The automated domain name registration application updates the name server with the intersection between the IP addresses configured for the member and the set of IP addresses active on the hosts in the sysplex. The DNS names dynamically added to the name server take the form *host_name.domain_suffix*, where *host_name* is the name of the member being registered to the GWM and *domain_suffix* is the domain suffix name specified in a zone parameter on a *dns* statement.

See the description of *domain_suffix* in “[dns statement](#)” on page 373 for total length restrictions.

Syntax

➤ *host_group* — *host_group_label* — Put Braces and Parameters on Separate Lines ➤

Put Braces and Parameters on Separate Lines

member

Parameters

host_group

The keyword that defines the beginning of the host_group statement.

host_group_label

A string 1 - 32 characters in length for the label of this host group. This value is referenced from automated domain name registration commands.

host_group_name *host_group_name*

The name of the group of hosts to be updated in the name server. This is the default host name for a member defined without a *host_name* parameter.

Restrictions:

- The name must be less than or equal to 63 characters in length.
- The name cannot contain any periods.
- Within the entire configuration file, a group name must be unique. The *host_group_name* value cannot be used on any other host_group statements or be used on any other server_group statements as a *server_group_name* value.

dns *dns_label*

A label referencing the dns statement that defines the DNS server with which to register the domain name and IP addresses. The value specified matches the *dns_label* on a dns statement.

zone *zone_label*

A label referencing a zone on the DNS server that is identified by the dns keyword. The value specified matches the *zone_label* value on a dns statement.

member

The members for a given group. The member might refer to a single TCP/IP host instance or might apply to the host group itself.

host_name *host_name*

The name of the individual host to be updated in the name server. If the *host_name* value is not specified, the member statement applies to the host group itself and not an individual host.

Rules:

- Only one member can be defined for a host group without a host_name definition.
- The name must be less than or equal to 63 characters in length.
- The name cannot contain any periods.

ipaddrlist *ipaddrlist_label*

A label referencing an ipaddrlist statement. This list contains one or more IP addresses to register. These IP addresses can be IPv4 or IPv6 addresses.

Guideline: For increased availability, specify VIPAs to identify the host.

ipaddrlist statement

Use the ipaddrlist statement to define a set of IP addresses that are referenced by members of host_group and server_group statements in the automated domain name registration application configuration file.

Syntax

►► ipaddrlist — *ipaddrlist_label* — Put Braces and Parameters on Separate Lines ►►

Put Braces and Parameters on Separate Lines

►► { — ipaddr *ipaddr* — } ►►

Parameters

ipaddrlist

The keyword that defines the beginning of the ipaddrlist statement.

ipaddrlist_label

A string 1 - 32 characters in length for the label of this ipaddrlist statement. This value is referenced from other statements in the automated domain name registration application configuration file.

ipaddr *ipaddr*

A single IP address to register. Multiple *ipaddr* values can be specified if there is more than one IP address associated with a host group or server group.

Guideline: These IP addresses can be a combination of IPv4 and IPv6 addresses.

key statement

Use the key statement to define the key name and key file to use when creating signatures for specifying transaction signatures (TSIGs) for zone updates and zone transfers.

Syntax

►► key — *key_label* — Put Braces and Parameters on Separate Lines ►►

Put Braces and Parameters on Separate Lines

►► { — keyfile *file_name* — } ►►

Parameters

key

The keyword that defines the beginning of the key statement.

key_label

A string 1 - 32 characters in length for the label of the key used in creating signatures. This name is referenced by the update_key or transfer_key keywords on a dns statement in the automated domain name registration application configuration file.

keyfile *file_name*

The file that contains the shared secret used in creating signatures.

Rules:

- The *file_name* value must be a fully qualified name of a z/OS UNIX file.
- Both the .key and the .private key files generated by the dnssec-keygen utility must be available for TSIG authentication to work correctly, even though only the .key key file name is specified by the *file_name* value.
- The file name is case sensitive. For TSIG authentication to work properly, the file name extensions must be .key and .private.

server_group statement

Use the `server_group` statement to identify the set of IP addresses to update for a group of servers. The automated domain name registration application updates the name server with the intersection between the IP addresses configured to the automated domain name registration application and the set of IP addresses on which the servers are listening.

The DNS names dynamically added to the name server take the following form `server_group_name.domain_suffix`, where *server_group_name* is the name of the individual server instance being registered to the GWM, *server_group_name* is the name of the group of servers, which includes *server_name*, and *domain_suffix* is the domain suffix name specified in a zone parameter on a `dns` statement.

The automated domain name registration application can also update individual server instances with the DNS server using the member keyword. The automated domain name registration application updates the name server with the intersection between the IP addresses configured for the member and the set of IP addresses on which the server is listening. The DNS names dynamically added to the name server take the form `server_name.server_group_name.domain_suffix`, where *server_name* is the name of the individual server instance being registered to the GWM, *server_group_name* is the name of the group of servers which includes *server_name*, and *domain_suffix* is the domain suffix name specified in a zone parameter on a `dns` statement.

See the description of *domain_suffix* in “[dns statement](#)” on page 373 for total length restrictions.

Syntax

►► `server_group` — *server_group_label* — Put Braces and Parameters on Separate Lines ►►

Put Braces and Parameters on Separate Lines

►► { — member — *port:port* — *protocol:protocol* — *server_group_name* *server_group_name* —
 ► *dns dns_label* — *zone zone_label* — } ►►

member

►► *member* — { — *server_name* — *server_name* — *ipaddrlist* — *ipaddrlist_label* — ►►

Parameters

`server_group`

The keyword that defines the beginning of the `server_group` statement.

server_group_label

A string 1 - 32 characters in length for the label of this server group. This value is referenced from automated domain name registration commands.

port *port*

The port on which the server is listening.

The valid range of port values is 1 - 65535.

protocol *protocol*

The transport protocol used by the application. This value must be TCP or UDP.

server_group *server_group_name*

The name of the group of servers to be registered with DNS server. This is the default server name for a member defined without a *server_name* parameter.

Rules:

- The name must be less than or equal to 63 characters in length.
- The name cannot contain any periods.
- Within the entire configuration file, a group name must be unique. The *server_group_name* value cannot be used on any other *server_group* statements or be used on any other *host_group* statements as a *host_group_name* value.

dns *dns_label*

A label referencing a dns statement that defines the DNS server with which to register the domain name and IP addresses. The value specified matches the *dns_label* value on a dns statement.

zone *zone_label*

A label referencing a zone on the DNS server that is identified by the dns keyword. The value specified matches a *zone_label* value on a dns statement.

member

The members for a given group. The member might refer to a single TCP/IP server instance or it might apply to the server group itself.

server_name *server_name*

The name of the individual server to be registered with the DNS server. If this parameter is not specified, then the member statement applies to the server group itself and not an individual server. Specifying a *server_name* value enables clients to connect to a particular instance of a server that is a member of a server group.

Rules:

- Only one member can be defined for a server group without a *server_name* definition.
- The name must be less than or equal to 63 characters in length.
- The name cannot contain any periods.

ipaddrlist *ipaddrlist_label*

A label referencing an ipaddrlist statement. This list contains one or more IP addresses to register for this server or server group.

Guidelines:

- These IP addresses can be IPv4 or IPv6 addresses.
- For increased availability, specify DVIPAs and VIPAs to identify the server or server group.

uuid statement

Use the uuid [(Universally Unique ID (UUID))] statement to uniquely identify this automated domain name registration application instance and distinguish it from all other SASP external load balancers. The GWM uses this unique user ID to distinguish one SASP entity from another.

Requirement: This statement is required.

Syntax

➤ `uuid` — *uuid* ➤

Parameters

uuid

The keyword that defines the beginning of the `uuid` statement.

uuid

The *uuid* value is an EBCDIC string 1 - 64 characters in length. Do not enclose the string in quotation marks.

Chapter 8. IKE daemon

This topic contains the following information:

- [“Starting the IKED using z/OS UNIX” on page 383](#)
- [“IKE cataloged procedure” on page 383](#)
- [“IKE environment variables” on page 384](#)
- [“IKE daemon configuration file statements” on page 386](#)

Starting the IKED using z/OS UNIX

Start the IKED from the z/OS shell using the following syntax:

➤➤ iked ➤➤

Tip: When you are starting the IKE daemon from the z/OS UNIX shell, set the environment variable `_BPX_JOBNAME`. This enables a specific job name to be used when reserving ports for the IKE daemon. You can also use this name with the STOP or MODIFY console commands. For more information about `_BPX_JOBNAME`, see [z/OS UNIX System Services Planning](#).

IKE cataloged procedure

This topic shows the IKE cataloged procedure.

Update the cataloged procedure, IKED, by copying the sample in SEZAINST(IKED), to your system or recognized PROCLIB. Specify IKE daemon parameters and change the data set names to suit your local configuration. See SEZAINST(EZARACF) for SAF considerations for started procedures. After the IKED procedure has been started, a different IKED configuration file can be specified by using the Modify command with the FILE parameter. For example:

```
MODIFY IKED,REFRESH,FILE='/etc/security/iked.conf2'
```

```

//IKED      PROC
//*
//* IBM Communications Server for z/OS
//* SMP/E distribution name: EZBIKPRC
//*
//* 5650-ZOS Copyright IBM Corp. 2005, 2013
//* Licensed Materials - Property of IBM
//* "Restricted Materials of IBM"
//* Status = CSV2R1
//*
//*
//IKED      EXEC PGM=IKED,REGION=OK,TIME=NOLIMIT,
//          PARM='ENVAR("_CEE_ENVFILE_S=DD:STDENV")/'
//*
//* Provide environment variables to run with the desired
//* configuration. As an example, the data set or file specified by
//* STDENV could contain:
//*
//* IKED_FILE=/etc/security/iked.conf2
//* IKED_CTRACE_MEMBER=CTIIKE01
//* IKED_CODEPAGE=IBM-1047
//*
//*
//* If you want to include comments in the data set or
//* z/OS UNIX file, specify the _CEE_ENVFILE_COMMENT
//* environment variable as the first environment variable
//* in the data set or file. The value specified for
//* the _CEE_ENVFILE_COMMENT variable is the comment character.
//* For example, if you want to use the pound sign, #, as
//* the comment character, specify this as the first
//* statement:
//* _CEE_ENVFILE_COMMENT=#
//*
//* For information on the above environment variables, refer to the
//* IP Configuration Reference.
//*
//STDENV    DD DUMMY
//* Sample MVS data set containing environment variables:
//*STDENV    DD DSN=TCPIP.IKED.ENV(IKED),DISP=SHR
//* Sample HFS file containing environment variables:
//*STDENV    DD PATH='/etc/security/iked.env',PATHOPTS=(ORDONLY)
//*
//* Output written to stdout and stderr goes to the data set or
//* file specified with SYSPRINT or SYSOUT, respectively.
//SYSPRINT DD SYSOUT=*
//SYSOUT   DD SYSOUT=*

```

Figure 13. IKE cataloged procedure

IKE environment variables

Table 16 on page 385 provides a list of environment variables used by IKE that can be tailored to a particular installation.

Table 16. IKE environment variables

Environment variable	Server, Client or Command-type application	Description	Any specific coding rules
IKED_CODEPAGE	Server	Used by the IKE daemon to specify the EBCDIC code page to be used for the configuration file. The default code page is IBM-1047.	<p>The following code pages are supported:</p> <ul style="list-style-type: none"> • IBM-037 • IBM-273 • IBM-274 • IBM-275 • IBM-277 • IBM-278 • IBM-280 • IBM-281 • IBM-282 • IBM-284 • IBM-285 • IBM-297 • IBM-500 • IBM-871 • IBM-1047 • IBM-1140 • IBM-1141 • IBM-1142 • IBM-1143 • IBM-1144 • IBM-1145 • IBM-1146 • IBM-1147 • IBM-1148 • IBM-1149 <p>Example:</p> <pre>IKED_CODEPAGE=IBM-1141</pre>
IKED_FILE	Server	Used by the IKE daemon in the search order for the IKE daemon configuration file. For details on the search order used for locating this configuration file, see Table 1 on page 1	<p>Examples:</p> <pre>IKED_FILE=/etc/security/iked.conf</pre> <pre>IKED_FILE=/'SYS1.TCPPARMS(IKECONF)'</pre>

Table 16. IKE environment variables (continued)			
Environment variable	Server, Client or Command-type application	Description	Any specific coding rules
IKED_CTRACE_MEMBER	Server	Used by the IKE daemon to specify the name of a parmlib member that contains default CTRACE settings. The IKED_CTRACE_MEMBER environment variable is read by the IKE daemon only during initialization. Changes to the IKED_CTRACE_MEMBER after daemon initialization have no effect.	If not defined, the default value used by the IKE daemon is CTIIKE00. Example: <pre>IKED_CTRACE_MEMBER=CTIIKE00</pre>

IKE daemon configuration file statements

If you specify a configuration file for the IKE daemon, the file must contain an `IkeConfig` statement. If you are using network security services, this file might also contain one `NssStackConfig` statement for each z/OS network security services (NSS) client TCP/IP stack. If you specify multiple `IkeConfig` statements, the last one is used; if you define multiple `NssStackConfig` statements for the same stack name, the last one is used.

If no configuration file is specified, then defaults are provided for `IkeConfig` parameters where possible. However, because there are no reasonable defaults for the `NssStackConfig` statements or the z/OS network security services (NSS) server-related parameters of the `IkeConfig` statement, it is not possible to have any NSS client TCP/IP stacks. All stacks in this case are handled using local services available to the IKE daemon.

If a configuration error is detected during startup, then the IKE daemon logs the error and exits. If a configuration error is detected during a dynamic refresh, then the entire refresh is rejected, the error is logged, and the IKE daemon continues running with the old configuration values.

Tip: The terms phase 1 and phase 2 refer to different types of security associations (SAs) that the z/OS IKE daemon can negotiate with its peers. Although the specific terminology for these types of security associations differs between the IKE version 1 and IKE version 2 protocols, the terms phase 1 and phase 2 refers to both versions, as shown in [Table 17](#) on page 386.

Table 17. IKE terminology: phase 1 and phase 2	
Term	Usage in regard to IKE protocol version
Phase 1 security association (SA)	Refers to IKE version 1 phase 1 SAs as well as IKE version 2 IKE SAs. When a specific version is intended, that version is identified in this document.
Phase 2 security association (SA)	Refers to IKE version 1 phase 2 SAs as well as IKE version 2 child SAs. When a specific version is intended, that version is identified in this document.

IkeConfig statement

If you code more than one IkeConfig statement, the last statement is used. Likewise, if a parameter other than SMF119 or SupportedCertAuth in the IkeConfig statement is specified more than once, the value from the last statement is used. SMF119 adds to, but does not replace, the types of SMF records to be written. SupportedCertAuth is used to define a set of certificate authorities (CAs) this value adds to, but does not replace, the list of CAs supported by a local security endpoint.

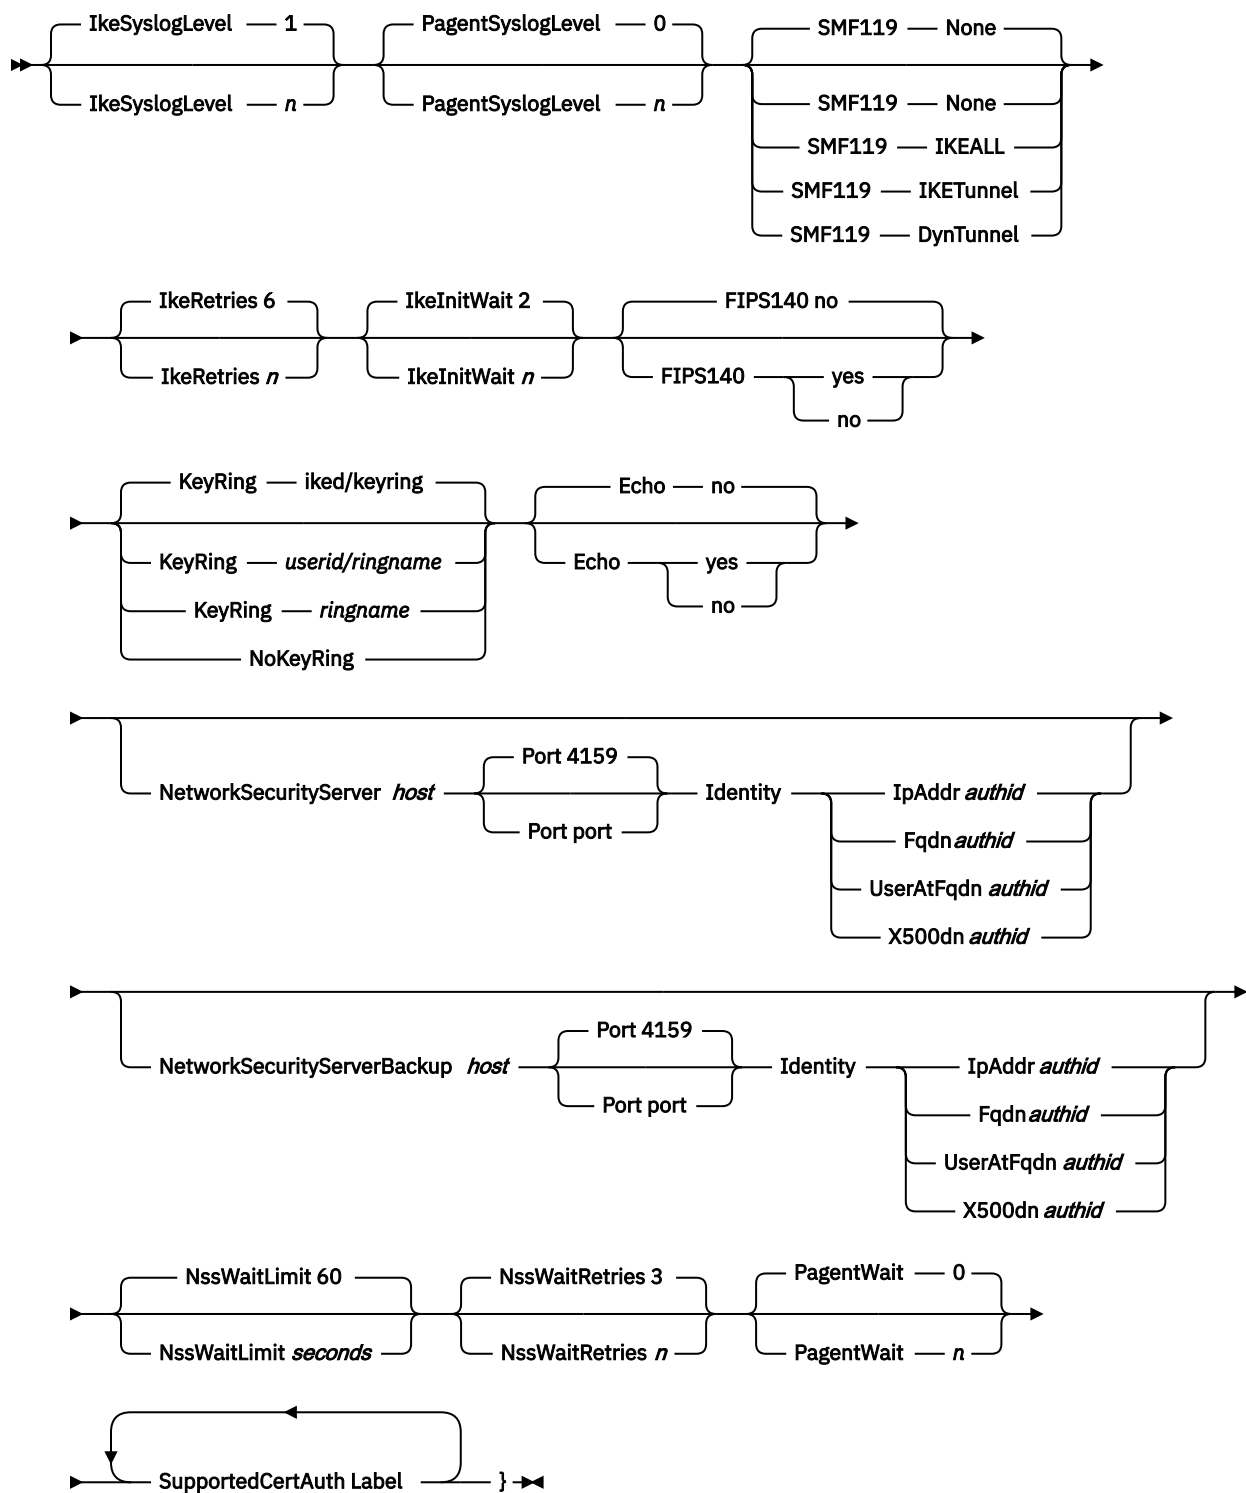

Syntax

►► IkeConfig — Braces & Params on Separate Lines ◄◄

Braces & Params on Separate Lines

IkeConfig Parameters

Parameters

IkeSyslogLevel

Specifies the level of logging to obtain from the IKE daemon. The following levels are supported:

0 - IKE_SYSLOG_LEVEL_NONE

Disable IKE daemon syslog messages

1 - IKE_SYSLOG_LEVEL_MINIMUM

Minimal IKE daemon syslog output

2 - IKE_SYSLOG_LEVEL_SADETAIL

Always output detailed Security Association (SA) information when available

4 - IKE_SYSLOG_LEVEL_DEBUGSA

Debug for SA negotiations

8 - IKE_SYSLOG_LEVEL_FMTPKTTRC

Formatted packet trace

16 - IKE_SYSLOG_LEVEL_UNFPKTTRC

Unformatted packet trace

32 - IKE_SYSLOG_LEVEL_VERBOSE

Show cascaded error messages

64 - IKE_SYSLOG_LEVEL_CERTINFO

Show certificates in CA cache when cache is initially built or rebuilt

128 - IKE_SYSLOG_LEVEL_DEBUGPTP

Show additional information regarding primary thread pool scheduling

To specify a combination of log levels, add the level numbers. For example, to request FMTPKTTRC (8) messages and VERBOSE (32) messages, specify `IkeSyslogLevel 40`. Use the `MODIFY IKED,REFRESH` command to change this value. Level values greater than 1 are intended for diagnostic purposes only. A non-zero `PagentSyslogLevel` will take effect only if `IkeSyslogLevel` is also set to a non-zero value, otherwise no debug trace records are generated.

Rules:

- The default `IkeSyslogLevel` is in effect until the parameter is read from the configuration file.
- Any level higher than 1 automatically includes 1.

PagentSyslogLevel

Specifies the level of diagnostic logging to obtain for the interaction between the IKE daemon and the Policy Agent. The following levels are supported:

0 - PAGENT_SYSLOG_LEVEL_NONE

No logging of IKE daemon interactions with the Policy Agent.

1 - PAGENT_SYSLOG_LEVEL_EMERG

A panic condition

2 - PAGENT_SYSLOG_LEVEL_ALERT

Requires immediate action

4 - PAGENT_SYSLOG_LEVEL_CRIT

Critical condition

8 - PAGENT_SYSLOG_LEVEL_ERR

Error messages

16 - PAGENT_SYSLOG_LEVEL_WARNING

Warning messages

32 - PAGENT_SYSLOG_LEVEL_NOTICE

Conditions that are not error conditions, but might require special handling

64 - PAGENT_SYSLOG_LEVEL_INFO

Informational messages

128 - PAGENT_SYSLOG_LEVEL_DEBUG

Messages that contain information normally of use only when debugging a program

To specify a combination of log levels, add the level numbers. For example, to request `LEVEL_EMERG` (1) messages and `LEVEL_WARNING` (16) messages, specify `PagentSyslogLevel 17`. Use the `MODIFY IKED,REFRESH` command to change this value. Level values greater than 0 are intended for diagnostic purposes only. A non-zero `PagentSyslogLevel` will take effect only if `IkeSyslogLevel` is also set to a non-zero value, otherwise no debug trace records will be generated.

SMF119

Specifies the types of SMF 119 records to be written to the MVS SMF data sets. The following levels are supported:

None

No SMF 119 records should be written to the MVS SMF data sets. This is the default.

IKEAll

All SMF 119 records should be written to the MVS SMF data sets. This setting includes all of the SMF 119 record types listed in this topic.

IKETunnel

SMF record type 119 subtypes related to phase 1 SA events should be written (subtypes 73 and 74) to the MVS SMF data sets.

DynTunnel

SMF record type 119 subtypes related to phase 2 SA events should be written (subtypes 75 and 76) to the MVS SMF data sets.

To specify a combination of records to be written, specify multiple SMF119 statements. Use the MODIFY IKED,REFRESH command to change this value.

KeyRing

The owning *userid* and *ringname* used by the IKE server when performing RSA signature mode of authentication. When using a key ring owned by a user ID other than the IKED user ID, *userid* must be specified. However, even if the keyring is owned by IKED's user ID, it is still helpful to specify *userid* to simplify certificate-related problem diagnosis.

The KeyRing parameter is not used by NSS client TCP/IP stacks.

Restriction:

- The KeyRing and NoKeyRing parameters are mutually exclusive. If you configure both in the same IkeConfig statement, it is treated as an error.
- The KeyRing parameter cannot be refreshed with the MODIFY IKED,REFRESH command.

NoKeyRing

Indicates that there is no IKED key ring.

Tip: If no TCP/IP stacks on this system use IKED for certificate services, configure NoKeyRing to prevent IKED attempting to open the default key ring iked/keyring. For example, if NSS is providing certificate services to IKED for all TCP/IP stacks on this system, NoKeyRing could be configured.

Restriction:

- The KeyRing and NoKeyRing parameters are mutually exclusive. If you configure both in the same IkeConfig statement, it is treated as an error.
- The NoKeyRing parameter cannot be refreshed with the MODIFY IKED,REFRESH command.

IkeRetries

Specifies the number of times that an unanswered IKE negotiation message is retransmitted before the negotiation is terminated. The value of *n* can be in the range 1 - 8. The default is six retransmissions (254 seconds before dropping the message exchange if the default IkeInitWait value of two seconds is used). The IKE server uses an exponentially increasing wait interval between each retransmission. The initial wait interval is specified by the IkeInitWait parameter, and each subsequent wait interval is doubled from there. For example, if the IkeInitWait value is two, the first retransmission comes after two seconds, the second comes four seconds after the first, the fourth eight seconds after the third, and so on. Use the MODIFY IKED,REFRESH command to change this value.

Table 18 on page 391 illustrates how a retransmission scenario would occur using the default values of IkeRetries 6 and IkeInitWait 2. The following scenario assumes that the IKE partner never responds to the IKE message in question.

<i>Table 18. Example of an IkeRetries retransmission scenario</i>		
Event	Seconds since last event	Elapsed time in seconds
Send initial message	0	0
1st wait interval expires: message retransmitted	2	2
2nd wait interval expires: message retransmitted	4	6
3rd wait interval expires: message retransmitted	8	14
4th wait interval expires: message retransmitted	16	30
5th wait interval expires: message retransmitted	32	62
6th wait interval expires: message retransmitted	64	126
7th wait interval expires: message exchange is dropped	128	254 (See note)
Note: * 4 minutes, 14 seconds		

Table 19 on page 391 illustrates how retransmission scenario would occur using the maximum values of IkeRetries 8 and IkeInitWait 15. This scenario assumes that the IKE partner never responds to the IKE message in question.

<i>Table 19. Example of an IkeRetries retransmission using maximum values scenario</i>		
Event	Seconds since last event	Elapsed time in seconds
Send initial message	0	0
1st wait interval expires: message retransmitted	15	15
2nd wait interval expires: message retransmitted	30	45
3rd wait interval expires: message retransmitted	60	105
4th wait interval expires: message retransmitted	120	225
5th wait interval expires: message retransmitted	240	465
6th wait interval expires: message retransmitted	480	945
7th wait interval expires: message retransmitted	960	1905
8th wait interval expires: message retransmitted	1920	3825
9th wait interval expires: message exchange is dropped	3840	7665

Table 19. Example of an IkeRetries retransmission using maximum values scenario (continued)		
Event	Seconds since last event	Elapsed time in seconds
Note: * 2 hours, 7 minutes, 45 seconds		

Table 20 on page 392 illustrates how retransmission scenario would occur using the minimum values of IkeRetries 1 and IkeInitWait 1. This scenario assumes that the IKE partner never responds to the IKE message in question:

Table 20. Example of an IkeRetries retransmission using minimum values scenario		
Event	Seconds since last event	Elapsed time in seconds
Send initial message	0	0
1st wait interval expires: message retransmitted	1	1
2nd wait interval expires: message exchange is dropped	2	3

IkeInitWait

Specifies the number of seconds to wait before the first retransmission of an unanswered IKE message. The value of *n* can be in the range 1 - 15. The default is 2 seconds. Use the MODIFY IKED,REFRESH command to change this value.

FIPS140

Specifies whether the IKE daemon should perform cryptographic operations by invoking cryptographic modules that are designed to meet the Level 1 security requirements documented in the Federal Information Processing Standard (FIPS) publication 140 (FIPS 140).

yes

Perform all IKE daemon cryptographic operations using cryptographic modules that are designed to meet FIPS 140 requirements. When the value of yes is specified, the IKE daemon server is running in FIPS 140 mode.

no

IKE daemon might perform some cryptographic operations using cryptographic modules that do not adhere to the FIPS 140 requirements. When the value of no is specified, the IKE daemon is not running in FIPS 140 mode.

Requirement: ICSF must be active before starting the IKE daemon when FIPS140 YES is specified. For information about configuring ICSF to support FIPS 140-2, see [Operating in compliance with FIPS 140-2 in z/OS Cryptographic Services ICSF Writing PKCS #11 Applications](#).

Rule: This parameter cannot be modified while the IKED is running. Attempts to modify the value while the IKED is running are ignored and a warning message is issued.

Tip: Enabling FIPS 140 mode provides a higher degree of assurance of the integrity of the cryptographic modules that IKE uses, including ICSF and System SSL. However, enabling FIPS 140 mode might require additional setup and configuration, it will restrict the available set of cryptographic algorithms, and it might result in a reduction in performance. See [Cryptographic standards and FIPS 140 in z/OS Communications Server: IP Configuration Guide](#) for more information.

Echo

Specifies whether the body of log messages generated by the IKE daemon should be echoed to the job output file. The job output file is specified by the SYSPRINT DD (JCL) statement in the IKED cataloged procedure.

yes

Indicates the body of IKE daemon log messages generated should be echoed to the job output file.

no

Indicates the body of IKE daemon log messages generated should not be echoed to the job output file.

Use the MODIFY IKED,REFRESH command to change this value.

Restriction: Only the body of the IKE daemon log message is echoed to the job output file. The body of IKE daemon log messages does not include the syslog message header or message instance information. The syslog message header is prepended to the message body by the syslog C/C++ library function before forwarding the message to the logging facility. It contains diagnostic information such as a timestamp. Message instance information is added to the message body by the IKED. It is used to group sets of related messages together. The syslog message header and message instance information are useful when performing problem determination. It is highly recommended that the syslogd facility be configured to collect IKED log records even when a values of yes is configured for the echo parameter.

Tip: The volume of log messages generated by the IKE daemon can be controlled by the IkeSyslogLevel parameter.

NetworkSecurityServer

Identifies the primary NSS server for IKE NSS client TCP/IP stacks.

A single server is used for all of the TCP/IP stacks configured as NSS clients. Stacks can be configured individually as NSS clients. Stacks with a corresponding NssStackConfig statement are treated as NSS clients; stacks without a corresponding NssStackConfig statement rely solely on local IKE resources.

Tip: The NetworkSecurityServer parameter is optional. However, if both the NetworkSecurityServer and NetworkSecurityServerBackup parameters are not specified, none of the TCP/IP stacks can function as an NSS client.

Use the MODIFY IKED,REFRESH command to change this value. If you change the NetworkSecurityServer value, the changes take effect for new connections, but existing connections are not dropped. If you want the old connections to be dropped, perform the following steps:

1. Comment out the following statements:
 - NetworkSecurityServer statement (if present)
 - NetworkSecurityServerBackup statement (if present)
 - NssStackConfig statements (if present)
2. Issue a MODIFY IKED, REFRESH command to re-read the IKED configuration file.
3. Uncomment the following statements:
 - NetworkSecurityServer statement (if present)
 - NetworkSecurityServerBackup statement (if present)
 - NssStackConfig statements (if present)
4. Issue a MODIFY IKED,REFRESH command to re-read the IKED configuration file.

host

The address of the NSS server can be specified either as a host name, a numeric IPv4 address, or a numeric IPv6 address. This is a required parameter. If a host name is specified, the maximum length accepted is 255 characters. The host name value should conform to the naming standards set forth by RFC 1035. For information about RFC, see [Appendix C, “Related protocol specifications,” on page 1349](#).

Examples of supported host identifiers are as follows:

```
163.44.212.11
1080:0:0:0:8:800:200C:417A
norton.nycsanitation.gov
```

Port port

The TCP port on which the NSS server is listening for connections from the IKE daemon. The default value is 4159. Valid values are in the range 1 - 65535.

This parameter is optional.

Identity

The identity of the NSS Server. This is a required parameter.

The IKE daemon requires that communication with an NSS Server be protected using AT-TLS. During the AT-TLS handshake, the NSS server provides a certificate that is used to authenticate its identity. The IKE daemon interrogates this certificate and verifies that the identity in the certificate matches the identity specified on the NetworkSecurityServer parameter of the IkeConfig statement.

The identity value from the NetworkSecurityServer statement can be configured in various ways:

- If IpAddr, Fqdn, or UserAtFqdn is specified then that value is compared to the value in the certificate's Subject Alternate Name (SAN) extension.
- If x500dn is specified then that value is compared to the certificate's subject name.

The following identity types (for *idtype*) and formats (for *authid*) are supported:

IpAddr

Indicates that the *authid* value is a numeric IPv4 address or a numeric IPv6 address. For example, 1.2.3.4.

Fqdn

Indicates that the *authid* value is a fully qualified domain name or host name. For example, vnet.ibm.com. The maximum length accepted is 255 characters. The Fqdn value should conform to the naming standards set forth by RFC 1035.

UserAtFqdn

Indicates that the *authid* value is a user at a fully qualified domain name or host name. The user name cannot contain a blank. For example, ibm@vnet.ibm.com. The maximum length accepted is 512 characters. The UserAtFqdn value should conform to the naming standards set forth by RFC 822.

X500dn

Indicates that the *authid* value is an X.500 distinguished name (DN). The DN must be specified in accordance with RFC 2253. A double-byte character is represented using the escaped UTF-8 encoding of the double-byte character in the Unicode character set. Attribute types can be specified using either attribute names or numeric object identifiers. Attribute values must represent string values. Attribute values must be delimited by commas.

Any distinguished name that contains an imbedded blank must be enclosed in double quotes. For example, X500dn "CN=R. Kramden,T=Driver,O=Gotham Bus Company,C=US".

Table 21 on page 394 lists the DN attribute names that are recognized by the System SSL run time. An error is returned if the DN contains an unrecognized attribute name.

Table 21. DN attribute names	
Abbreviation	Meaning
C	Country
CN	Common name
DC	Domain component
E	E-mail address
EMAIL	E-mail address (preferred)
EMAILADDRESS	E-mail address

Table 21. DN attribute names (continued)	
Abbreviation	Meaning
L	Locality
O	Organization name
OU	Organizational unit name
PC	Postal code
S	State or province
SN	Surname
SP	State or province
ST	State or province (preferred)
STREET	Street
T	Title

The following code is an example of a DN using attribute names and string values:

```
CN=Hoffman,OU=Endicott,O=IBM,C=US
```

The following code is the same DN using object identifiers and encoded string values. The encoded string values represent the ASN.1 DER encoding of the string. The System SSL run time supports the following ASN.1 string types: PRINTABLE, VISIBLE, TELETEX, IA5, UTF8, BMP, and UCS.

```
2.5.4.3=#130E526F6E616C6420486F666666D616E,2.5.4.11=
#1308456E6469636F7474, 2.5.4.10=#130349424D,2.5.4.6=#13025553
```

Individual characters can be represented using escape sequences. This is useful when the character cannot be represented in a single-byte character set. The hexadecimal value for the escape sequence is the UTF-8 encoding of the character in the Unicode character set. [Table 22 on page 395](#) shows some Unicode example letter descriptions.

Table 22. Unicode letter descriptions			
Unicode letter description	10646 code	UTF-8	Quoted
LATIN CAPITAL LETTER L	U0000004C	0x4C	L
LATIN SMALL LETTER U	U00000075	0x75	u
LATIN SMALL LETTER C WITH CARON	U0000010D	0xC48D	\C4\8D
LATIN SMALL LETTER I	U00000069	0x69	i
LATIN SMALL LETTER C WITH ACUTE	U00000107	0xC487	\C4\87

Guideline: The letters in the Quoted column in [Table 22 on page 395](#) can be used to encode a surname as follows:

```
SN=Lu\C4\8Di\C4\87
```

An escape sequence can also be used for special characters that are part of the name and are not to be interpreted as delimiters. The following special characters must be represented as an escape sequence (prefixed with a backslash [\]) when used as part of the name:

- A space or number sign (#) character occurring at the beginning of the string
- A space occurring at the end of the string
- One of the following characters , + " \ < >

This correct escape sequence is shown in the following example:

```
"CN=L. Eagle,OU=Jones\, Dale and Mian,O=IBM,C=US"
```

In this example, the enclosing double quotes are required because of the imbedded blanks, not because of the escaped characters.

Rule: When an X500dn type identity is specified, the DN attributes must have the same order as those of the corresponding certificate subject name.

NetworkSecurityServerBackup

Identifies the backup NSS server for the IKE daemon. The NSS server (or its backup) supplies certificate and remote management services for managed stacks.

A single backup server is used for all of the TCP/IP stacks configured as NSS clients.

The NetworkSecurityServerBackup parameter is optional. It allows network security clients to connect to a backup NSS server at a different address or port from the primary. Alternatively, in a sysplex configuration, the primary NSS server can be configured on a dynamic VIPA to use the recovery capabilities of dynamic addressing. If no backup server is available when the primary server is not responsive, certificate and remote management services are unavailable to network security clients. However, if a NetworkSecurityServerBackup parameter is not specified, then certificate services are unavailable to Network Security clients if the primary NSS server becomes unresponsive.

Network Security clients switch between the primary and the backup NSS servers whenever their current server becomes unresponsive. If both the primary and the backup become unresponsive, the Network Security client attempts to connect to the primary and the backup in a round-robin fashion until a successful connection is made. It is possible to have a situation where one NSS client is being managed by the primary server and another NSS client is being managed by the backup server. It is also possible to specify a backup server without specifying a primary server, in which case, the backup server is treated as if it is the primary server.

Use the MODIFY IKED, REFRESH command to change this value. If you change the NetworkSecurityServerBackup value, then the changes take effect for new connections, but existing connections are not dropped. If you want the old connections to be dropped, follow this following sequence:

1. Comment out all of the following statements:
 - NetworkSecurityServer statement (if present)
 - NetworkSecurityServerBackup statement (if present)
 - NssStackConfig statements (if present)
2. Issue a MODIFY IKED, REFRESH command to re-read the IKED configuration file.
3. Uncomment out all of the following statements:
 - NetworkSecurityServer statement (if present)
 - NetworkSecurityServerBackup statement (if present)
 - NssStackConfig statements (if present)
4. Issue a MODIFY IKED, REFRESH command to re-read the IKED configuration file.

host

The address of the NSS server can be specified either as a host name, a numeric IPv4 address, or a numeric IPv6 address. This is a required parameter. If a host name is specified, the maximum length accepted is 255 characters. The host name value should conform to the naming standards set forth by RFC 1035.

Examples of supported host identifiers are as follows:

```
163.44.212.11
1080:0:0:0:8:800:200C:417A
norton.nycsanitation.gov
```

Port port

The TCP port on which the backup NSS server is listening for connections from the IKE daemon. The default value is 4159. Valid values are in the range 1 - 65535. This parameter is optional.

Identity

The identity of the backup NSS server. This is a required parameter.

The IKE daemon requires that communication with an NSS server be protected using AT-TLS. During the AT-TLS handshake the NSS server provides a certificate that is used to authenticate its identity. The IKE daemon interrogates this certificate and verifies that the identity in the certificate matches the identity specified on the NetworkSecurityServer parameter of the IkeConfig statement.

The following identity types (*idtype*) and formats (*authid*) are supported:

IpAddr

Indicates that the *authid* value is a numeric IPv4 address or a numeric IPv6 address. For example, 1.2.3.4.

Fqdn

Indicates that the *authid* value is a fully qualified domain name or host name. For example, vnet.ibm.com. The maximum length accepted is 255 characters. The Fqdn value should conform to the naming standards set forth by RFC 1035.

UserAtFqdn

Indicates that the *authid* value is a user at a fully qualified domain name or host name. The user name cannot contain a blank. For example, ibm@vnet.ibm.com. The maximum length accepted is 512 characters. The UserAtFqdn value cannot begin or end with a dot (.) or contain consecutive dots. The UserAtFqdn value should conform to the naming standards set forth by RFC 822.

X500dn

Indicates that *authid* is an X.500 distinguished name (DN). See the NetworkSecurityServer parameter description in this topic for the DN specification.

NssWaitLimit

Specifies the number of seconds (1-300) that an NSS client waits between connection attempts when trying to establish a connection with an NSS server.

The product of the NssWaitLimit value multiplied by the NssWaitRetries value defines the maximum number of seconds that an NSS client attempts to connect to an NSS server before switching to another server. For example, if the NssWaitLimit value is 60, and the NssWaitRetries value is 3, then an NSS client waits at most for a total of 180 seconds for a successful connection with a given server. See the description of the NetworkSecurityServerBackup parameter for a discussion of how NSS clients switch between the primary and backup NSS servers.

The default value is 60 seconds. Use the MODIFY IKED,REFRESH command to change this value. The change does not take effect immediately for existing connections. An existing connection will have the NssWaitLimit and NssWaitRetries values that were in effect when the connection was established. If an existing connection is dropped or lost, only after NssWaitRetries connection attempts have failed will the connection attempts begin using the new NssWaitLimit and NssWaitRetries values.

To force the old connections to be dropped and the new values to be used, perform the following steps:

1. Comment out the following statements:

- NetworkSecurityServer statement (if present)
- NetworkSecurityServerBackup statement (if present)
- NssStackConfig statements (if present)

2. Issue a MODIFY IKED, REFRESH command to re-read the IKED configuration file.
3. Uncomment the following statements:
 - NetworkSecurityServer statement (if present)
 - NetworkSecurityServerBackup statement (if present)
 - NssStackConfig statements (if present)
4. Issue a MODIFY IKED, REFRESH command to re-read the IKED configuration file.

NssWaitRetries

Specifies the number of times (1-10) that an NSS client attempts to establish a connection with an NSS server.

The product of the NssWaitLimit value multiplied by the NssWaitRetries value defines the maximum number of seconds that an NSS client attempts to connect to an NSS server before switching to another server. For example, if the NssWaitLimit value is 60, and the NssWaitRetries value is 3, then an NSS client waits at most for a total of 180 seconds for a successful connection with a given server. See the description of the NetworkSecurityServerBackup parameter for a discussion of how NSS clients switch between the primary and backup NSS servers.

The default value is 3 retries. Use the MODIFY IKED, REFRESH command to change this value. The change does not take effect immediately for existing connections. An existing connection will have the NssWaitLimit and NssWaitRetries values that were in effect when the connection was established. If an existing connection is dropped or lost, only after NssWaitRetries connection attempts have failed will the connection attempts begin using the new NssWaitLimit and NssWaitRetries values.

To force the old connections to be dropped and the new values to be used, perform the following steps:

1. Comment out the following statements:
 - NetworkSecurityServer statement (if present)
 - NetworkSecurityServerBackup statement (if present)
 - NssStackConfig statements (if present)
2. Issue a MODIFY IKED, REFRESH command to re-read the IKED configuration file.
3. Uncomment the following statements:
 - NetworkSecurityServer statement (if present)
 - NetworkSecurityServerBackup statement (if present)
 - NssStackConfig statements (if present)
4. Issue a MODIFY IKED, REFRESH command to re-read the IKED configuration file.

PagentWait

The time limit in seconds to wait for connection to the Policy Agent. The value of *n* can be 0-9999. A value of 0 indicates retry forever. The default is 0.

Restriction: The PagentWait parameter cannot be refreshed with the MODIFY IKED, REFRESH command.

SupportedCertAuth

Specifies the label of a certificate on the IKE server's key ring. This label corresponds to the certificate of a certificate authority supported by the local security endpoint when using RSA signature mode of authentication. RSA signature authentication is a certificate-based authentication method used by the IKE server to authenticate a remote security endpoint's identify. The SupportedCertAuth parameter can be specified multiple times to identify a set of supported certificate authorities.

Use the SupportedCertAuth parameter to define a set of certificate authorities (CAs) supported by the local security endpoint. This list is provided to the remote security endpoint to request that it choose a certificate signed by an acceptable CA. The remote security endpoint is not constrained to choose certificates signed by CAs accepted by the local security endpoint. However, if the remote

security endpoint chooses a certificate signed by a CA that is not on the IKE server's key ring, the key exchange fails.

The `CaLabel` parameter of the `RemoteSecurityEndpoint` IPsec policy statement can be used to further restrict the set of certificate authorities that can sign the certificate used by a particular remote security endpoint. The advantage of further restricting the set of certificate authorities that might sign the certificate used by a particular remote security endpoint is a reduction in the size of the IKE key exchange messages transmitted between the local security endpoint and the remote security endpoint.

The number of specified labels is limited to a maximum of 128. The maximum length of a label is 32 characters, which corresponds to the maximum length of a RACF label. The default is an empty list containing no labels.

Use the `MODIFY IKED,REFRESH` command to change this value.

The `SupportedCertAuth` parameter is not used by NSS server client TCP/IP stacks.

NssStackConfig statement

The `NssStackConfig` statement contains NSS server stack configuration information for the IKE daemon. Only stacks with a corresponding `NssStackConfig` statement are eligible for management services provided by network security services. Stacks that are not configured with an `NssStackConfig` statement do not use network security services.

Restriction: `NssStackConfig` statements require that a valid NSS server is set up in the `IkeConfig` statement. See the `NetworkSecurityServer` and `NetworkSecurityServerBackup` parameters in the `IkeConfig` statement. It is a configuration error to have an `NssStackConfig` statement without also specifying a `NetworkSecurityServer` parameter, a `NetworkSecurityServerBackup` parameter, or both.

If more than one `NssStackConfig` statement is coded for the same TCP/IP stack, the last one is used. Likewise, if a parameter within the `NssStackConfig` statement is specified more than once, the value from the last one is used.

Use the `MODIFY IKED,REFRESH` command to change which TCP/IP stacks are configured as NSS clients, as follows:

Deleting an NSS client

If it is determined after a refresh that an `NssStackConfig` statement was removed, then the connection associated with the removed `NssStackConfig` statement is closed.

Adding NSS client

If it is determined after a refresh that a new `NssStackConfig` statement was added, then the connection for the new stack is opened.

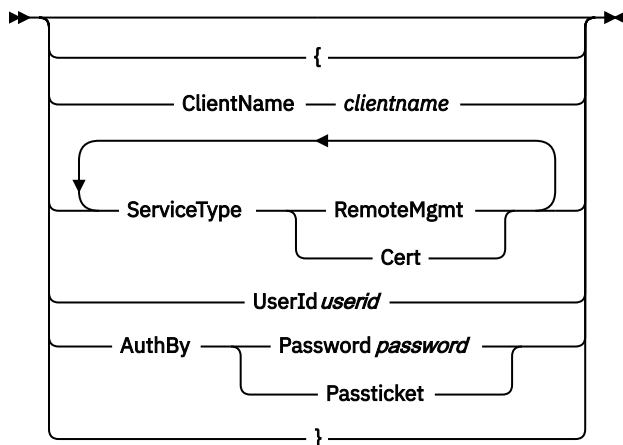

Changing internal NssStackConfig values

Any change to an internal parameter of the `NssStackConfig` statement results in a disconnect followed by a reconnect.

Syntax

➤ NssStackConfig — *stackname* — Braces & Params on Separate Lines ➤

Braces & Params on Separate Lines

Parameters

stackname

The name of the NSS client TCP/IP stack. This is a required parameter. There is no default value.

ClientName *clientname*

The NSS client name for the stack. By default, client names have the form *sysname_stackname*, where the *sysname* value is the MVS system name, and the *stackname* value is the TCP/IP stack name. This name must match the clientname portion of the associated SERVAUTH profile (EZB.NSS.sysname.clientname.IPSEC.CERT and EZB.NSS.sysname.clientname.IPSEC.NETMGMT) and can be 1 - 24 characters in length.

Restriction: Only alphanumeric characters (a-z, A-Z, 0-9), the hyphen (-), and the underscore (_) are valid for the ClientName parameter. Embedded spaces are also not permitted in the ClientName parameter; only trailing spaces are permitted.

If no client name is configured, then the IKE daemon generates this parameter based on the system's host name and the associated TCP/IP stack name.

For example, if the system host name is MVSIBM and the TCP/IP stack name is TCPCS, then the generated client name is MVSIBM_TCPCS.

ServiceType

The ServiceType parameter should be specified once for each network security service that is to be enabled for the stack. The following service types are supported:

RemoteMgmt

Indicates that this stack is eligible for remote management.

Cert

Indicates that this stack uses centralized certificate management.

Requirement: There must be at least one ServiceType statement in the NssStackConfig statement.

UserId *userid*

The RACF user ID that the NSS server uses to authenticate the NSS client and to verify its access to the SERVAUTH profiles that protect the certificate and remote management resources on the NSS server. User IDs can be 1 - 8 characters in length.

AuthBy

Authorization of the client TCP/IP stack to the NSS server can be accomplished either by the use of a password or by a Pass Ticket.

Password *password*

The *password* value is the RACF password for the user ID specified for the user. There is no default value for the *password* value; a valid password is required if password authentication is being used. Passwords can be 1 - 8 characters in length.

Passticket

The Pass Ticket option causes the client to generate a one-time session key. See the information about the secured signon function in [z/OS Security Server RACF Security Administrator's Guide](#).

Authby is a required parameter and there is no default value. Either the Password option or Passticket option (but not both), must be specified.

During the installation, ensure that you prevent access to the IKE configuration file by unauthorized users to protect this sensitive data. The most secure approach to protecting this information is to use Pass Tickets, which store the application keys in the RACF database.

IKE daemon configuration file sample

```
#
# IBM Communications Server for z/OS
# SMP/E distribution path: /usr/lpp/tcpip/samples/IBM/EZAIKCFG
#
# 5650-ZOS Copyright IBM Corp. 2007 - 2021.
# Licensed Materials - Property of IBM
# "Restricted Materials of IBM"
# Status = ZCSV2R5
#
# /etc/security/iked.conf (IKE daemon configuration)
#
# This file contains sample IKE daemon configuration parameters.
# The search order used by the IKE daemon to locate the initial
# configuration file is (highest priority listed first):
#
# 1) The name of a file or MVS data set specified by the IKED_FILE
#    environment variable.
# 2) /etc/security/iked.conf
#
# Some parameters may be dynamically modified after the
# IKE daemon has been started. The parameters that are
# dynamically modifiable are noted below.
#
# One way of dynamically modifying parameters is to edit
# the iked.conf file after the IKE daemon has been started and then
# issue a modify command to cause the IKE daemon to re-read the file.
#
# Example: MODIFY IKED,REFRESH
# Note: IKED is the IKE daemon procedure name.
#
# After the IKE daemon has been started, a different configuration
# file can be specified by using the Modify command with the FILE
# parameter. This allows modifiable parameters to be
# dynamically altered while the IKE daemon is running. Note that
# the parameter values modified in this fashion are not
# persistent. To make the changes persistent, edit the iked.conf
# file that is located at IKE initialization time according to the
# search order described previously.
#
# Example: MODIFY IKED,REFRESH,FILE='/etc/security/iked.conf2'
# Note: IKED is the IKE daemon procedure name.
#
# See the IP System Administrator's Commands book for more information
# about the modify command.
#
# See the IP Configuration Reference book for more information about
# the IkeConfig and NssConfig statements and their individual
# parameters.

IkeConfig
{
# IkeSyslogLevel    0-255                (dynamically modifiable)
# Specifies the level of logging to obtain from the IKE daemon.
# To specify a combination of log levels, add the level numbers.
# The supported levels are:
#   0 - IKE_SYSLOG_LEVEL_NONE            - Disable IKE daemon syslog messages
#   1 - IKE_SYSLOG_LEVEL_MINIMUM         - Minimal IKE daemon syslog output
```

```

# 2 - IKE_SYSLOG_LEVEL_SADETAIL - Always output detailed Security
#                               Association (SA) information when
#                               available
# 4 - IKE_SYSLOG_LEVEL_DEBUGSA - Include additional debug
#                               information for SA negotiations
# 8 - IKE_SYSLOG_LEVEL_FMPKTTTRC - Formatted IKE message trace
# 16 - IKE_SYSLOG_LEVEL_UNFMPKTTTRC - Unformatted IKE message trace
# 32 - IKE_SYSLOG_LEVEL_VERBOSE - Show cascaded error messages
# 64 - IKE_SYSLOG_LEVEL_CERTINFO - Show certificates in CA cache when
#                               cache is initially built or
#                               rebuilt
# 128 - IKE_SYSLOG_LEVEL_DEBUGPTP - Include additional information
#                               on the Primary Thread Pool
# Default: 1
# IkeSysLogLevel 1

# PageantSysLogLevel 0-255 (dynamically modifiable)
# Specifies the level of logging to obtain from pageant through the PAPI.
# To specify a combination of log levels, add the level numbers.
# The supported levels are:
# 1 - PAGENT_SYSLOG_LEVEL_EMERG - A panic condition
# 2 - PAGENT_SYSLOG_LEVEL_ALERT - Requires immediate action
# 4 - PAGENT_SYSLOG_LEVEL_CRIT - Critical condition
# 8 - PAGENT_SYSLOG_LEVEL_ERR - Error messages
# 16 - PAGENT_SYSLOG_LEVEL_WARNING - Warning messages
# 32 - PAGENT_SYSLOG_LEVEL_NOTICE - Notice messages
# 64 - PAGENT_SYSLOG_LEVEL_INFO - Informational messages
# 128 - PAGENT_SYSLOG_LEVEL_DEBUG - Debug messages
# Default: 0
# PageantSysLogLevel 0

# Keyring userid/ringname (not dynamically modifiable)
# The owning userid and ringname used by the IKE server when performing
# RSA Signature Mode of authentication. The userid must be the userid
# of the process under which IKE will run.
# Mutually exclusive with NoKeyring.
# Default: iked/keyring
# Keyring iked/keyring

# NoKeyring (not dynamically modifiable)
# Indicates that there is no IKED key ring.
# Mutually exclusive with Keyring.
# Default: None.
# NoKeyring

# IkeRetries 1-8 (dynamically modifiable)
# Specifies the number of times that an unanswered IKE negotiation
# message is retransmitted before the negotiation is cancelled.
# Default: 6
# IkeRetries 6

# IkeInitWait 1-15 (dynamically modifiable)
# Specifies the number of seconds to wait before the first
# retransmission of an unanswered IKE message
# Default: 2
# IkeInitWait 2

# FIPS140 yes,no (not dynamically modifiable)
# Specifies whether the IKE daemon should perform cryptographic
# operations by invoking cryptographic modules that are compliant with
# Federal Information Processing Standard (FIPS) publication 140-2's
# Level 1 security requirements.
# Default: no
# FIPS140 no

# Echo yes,no (dynamically modifiable)
# Echoes the message body of all IKE daemon log messages enabled by
# IkeSysLogLevel parameter to the job output file, specified by the
# SYSPRINT DD (JCL) statement.
# Default: no
# Echo no

# PageantWait 0-9999 (not dynamically modifiable)
# The time limit in seconds to wait for connection to the policy agent.
# A value of 0 means retry forever.
# Default: 0
# PageantWait 0

# SupportedCertAuth label (dynamically modifiable)
# Specifies the label of a Certificate Authority(CA) certificate on the
# IKE server's keyring. Use multiple instances of this keyword to
# specify multiple CA certificates.

```

```

# Default:          <none>

# NetworkSecurityServer address Port 4159 Identity IpAddr 1.2.3.4
# Default: none          #(dynamically modifiable)
# NetworkSecurityServerBackup address Port 4159 Identity IpAddr 2.2.3.4
# Default: none          #(dynamically modifiable)

# NssWaitLimit      1-300          (dynamically modifiable)
# Specifies the number of seconds that a Network Security client
# will wait between connection attempts when trying to establish a
# connection with a Network Security Server.
# Default: 60
NssWaitLimit 60

# NssWaitRetries    1-10          (dynamically modifiable)
# Specifies the number of times that a Network Security client will
# attempt to establish a connection with the primary Network Security
# Server before attempting to establish a connection with the backup
# server.
# Default: 3
NssWaitRetries 3

# SMF119            None, IKETunnel, DynTunnel, IKEAll (dynamically
#                                                            modifiable)
# Specifies the level of logging to send to the SMF facility.
# IKEAll is equivalent to specifying SMF119 IKETunnel and
# SMF119 DynTunnel on two separate lines.
# The supported levels are:
# None              No SMF records
# IKETunnel          Phase 1 related SMF records
# DynTunnel          Phase 2 related SMF records
# IKEAll             Phase 1 and Phase 2 related SMF records
# Default:           None
SMF119              None
}

# NssStackConfig    stackname      (dynamically modifiable)
# Used to configure a stack as a Network Security client.
# Use one NssStackConfig statement for each TCPIP stack that you wish
# to configure as a Network Security client. TCPIP stacks that do not
# have a corresponding NssStackConfig statement will be serviced by
# local IKE resources only.
#
# NssStackConfig    TCPCS
# {
# Clientname        clientname      (dynamically modifiable)
# Specifies the Network Security client name for the stack. Client
# names for stacks typically have the form sysname_stackname, where
# sysname is the MVS system name, and stackname is the TCP/IP stack
# name. This name must match the clientname portion of the associated
# SERVAUTH profiles:
#   - EZB.NSS.sysname.clientname.IPSEC.CERT
#   - EZB.NSS.sysname.clientname.IPSEC.NETMGMT
# The client name may be from 1 to 24 characters long.
# Default: <systemname>_<stackname>
# ClientName        MYSYSTEM_TCPCS
#
# ServiceType        RemoteMgmt, Cert (dynamically modifiable)
# Specifies that the stack is requesting a type of centralized
# management via a Network Security Server. This statement will occur
# once for each type of service that the stack is requesting. Supported
# service types are:
#   - RemoteMgmt
#   - Cert
# Defaults: None
# ServiceType        RemoteMgmt
# ServiceType        Cert
#
# Userid             userid          (dynamically modifiable)
# Specifies the RACF userid that will be used to verify access for this
# stack to the services provided by the Network Security Server. Userid
# may be from 1-8 characters long.
# Defaults: None.
# UserId             SMITHXYZ
#
# Authby             Password password (dynamically modifiable)
#                   Passticket (dynamically modifiable)
# Specifies the mechanism by which the Network Security Server should
# authenticate the client TCPIP stack. Supported mechanisms are RACF
# password or RACF passticket.
#
# Password           password

```

```
#      password is the RACF password for the userid specified for the
#      UserId.
#
#      Passticket
#      A RACF Passticket is generated for authorization.
#
# Default: none. One (and only one) of Password or Passticket must be
#      specified.
# Authby Password secretxyz
# }
```

Figure 14. Sample IKE daemon configuration file

Chapter 9. Network security services server

This topic contains the following information about the Network security services (NSS) server:

- [“Starting Network security services server using z/OS UNIX” on page 405](#)
- [“Network security services server cataloged procedure” on page 405](#)
- [“Network security services server environment variables” on page 406](#)
- [“Network security services server configuration file statements” on page 408](#)

Starting Network security services server using z/OS UNIX

Start NSS server from the z/OS shell using the following syntax:

➡ nssd ➡

Tip: When you are starting the NSS server from the z/OS UNIX shell, set the environment variable `_BPX_JOBNAME`. This enables a specific job name to be used when reserving ports for the NSS server. You can also use this name with the STOP or MODIFY console commands. For more information about `_BPX_JOBNAME`, see [z/OS UNIX System Services Planning](#).

Network security services server cataloged procedure

Update the cataloged procedure, NSSD, by copying the sample in SEZAINST(NSSD), to your system or recognized PROCLIB. Specify the NSS server parameters and change the data set names to suit your local configuration. See SEZAINST(EZARACF) for external security manager considerations for started procedures. After the NSSD procedure has been started, you can specify a different NSSD configuration file by using the Modify command with the FILE parameter. For example:

```
MODIFY NSSD,REFRESH,FILE='/etc/security/nssd.conf2'
```

```

//NSSD PROC
//*
//* IBM Communications Server for z/OS
//* SMP/E distribution name: EZBIMPRC
//*
//* 5650-ZOS Copyright IBM Corp. 2007, 2013
//* Licensed Materials - Property of IBM
//* "Restricted Materials of IBM"
//* Status = CSV2R1
//*
//*
//NSSD EXEC PGM=NSSD,REGION=0K,TIME=NOLIMIT,
// PARM='ENVAR("_CEE_ENVFILE_S=DD:STDENV")/'
//*
//* Provide environment variables to run with the desired
//* configuration. As an example, the data set or file specified by
//* STDENV could contain:
//*
//* NSSD_FILE=/etc/security/nssd.conf
//* NSSD_CTRACE_MEMBER=CTINSS01
//* NSSD_CODEPAGE=IBM-1047
//*
//* If you want to include comments in the data set or
//* z/OS UNIX file, specify the _CEE_ENVFILE_COMMENT
//* environment variable as the first environment variable
//* in the data set or file. The value specified for
//* the _CEE_ENVFILE_COMMENT variable is the comment character.
//* For example, if you want to use the pound sign, #, as
//* the comment character, specify this as the first
//* statement:
//* _CEE_ENVFILE_COMMENT=#
//*
//* For information on the above environment variables, refer to the
//* IP Configuration Reference.
//*
//STDENV DD DUMMY
//* Sample MVS data set containing environment variables:
//*STDENV DD DSN=TCPIP.NSSD.ENV(NSSD),DISP=SHR
//* Sample file containing environment variables:
//*STDENV DD PATH='/etc/security/nssd.env',PATHOPTS=(ORDONLY)
//*
//* Output written to stdout and stderr goes to the data set or
//* file specified with SYSPRINT or SYSOUT, respectively.
//SYSPRINT DD SYSOUT=*
//SYSOUT DD SYSOUT=*

```

Figure 15. NSSD cataloged procedure

Network security services server environment variables

Table 23 on page 407 provides a list of environment variables used by the NSS server that you can alter for a particular installation.

Table 23. NSS server environment variables

Environment variable	Description	Any specific coding rules
NSSD_CODEPAGE	Used by the NSS server to specify the EBCDIC codepage to be used for the configuration file. The default codepage is IBM-1047.	<p>The following codepages are supported:</p> <ul style="list-style-type: none"> • IBM-037 • IBM-273 • IBM-274 • IBM-275 • IBM-277 • IBM-278 • IBM-280 • IBM-281 • IBM-282 • IBM-284 • IBM-285 • IBM-297 • IBM-500 • IBM-871 • IBM-1047 • IBM-1140 • IBM-1141 • IBM-1142 • IBM-1143 • IBM-1144 • IBM-1145 • IBM-1146 • IBM-1147 • IBM-1148 • IBM-1149 <p>Example:</p> <pre>NSSD_CODEPAGE=IBM-1141</pre>
NSSD_FILE	Used by the NSS server in the search order for the NSS server configuration file. For details on the search order used for locating this configuration file, see “TCP/IP configuration data sets” on page 1 .	<p>If this environment variable is not defined, the default value used by the NSS server is <code>/etc/security/nssd.conf</code>.</p> <p>Examples:</p> <pre>NSSD_FILE=/etc/security/nssd.conf</pre> <pre>NSSD_FILE=// 'SYS1.TCPPARMS(NSSCONF) '</pre>

Table 23. NSS server environment variables (continued)		
Environment variable	Description	Any specific coding rules
NSSD_PIDFILE	Used by the NSS server in the search order for the NSS server PID file. The search order for the NSS server PID file is as follows: <ol style="list-style-type: none"> 1. NSSD_PIDFILE environment variable 2. /etc/nssd.pid 	If this environment variable is not defined, the default value used by the NSS server is /etc/nssd.pid. Example: <pre>NSSD_PIDFILE=/etc/nssd.pid</pre>
NSSD_CTRACE_MEMBER	Used by the NSS server to specify the name of a parmlib member that contains default CTRACE settings. The NSSD_CTRACE_MEMBER environment variable is read by the NSS server only during initialization. Changes to the NSSD_CTRACE_MEMBER after NSS server initialization have no effect.	If this environment variable is not defined, the default value used by the NSS server is CTINSS00. Example: <pre>NSSD_CTRACE_MEMBER=CTINSS00</pre>

Network security services server configuration file statements

The configuration of the NSS server contains parameters that define the behavior of the daemon. If any parameter is omitted from the configuration file, then default values are provided for parameters that support a default. If a configuration file is not specified, then default values are provided for all parameters.

If a configuration error is detected during startup, then the NSS server logs the error and exits. If a configuration error is detected during a dynamic refresh, then the entire refresh is rejected, the error is logged, and the NSS server continues running with the old configuration values.

The NSS server uses the following search order to locate the configuration file (highest priority is listed first):

1. The name of a file or MVS data set specified by the NSSD_FILE environment variable.
2. /etc/security/nssd.conf

Tip: You can use the IBM Configuration Assistant for z/OS Communications Server to establish NSS server settings. Establish the settings using the NSS perspective of the IBM Configuration Assistant for z/OS Communications Server, and then click **Install Configuration File** on the **Image Information** tab to store the generated NSS server configuration file on the z/OS system.

NSS server configuration file sample

This topic shows the NSS server configuration file sample.

```
#
# IBM Communications Server for z/OS
# SMP/E distribution path: /usr/lpp/tcpip/samples/IBM/EZANSCFG
#
# Licensed Materials - Property of IBM
# 5694-A01 Copyright IBM Corp. 2007, 2010
# Status = CSV1R12
#
# /etc/security/nssd.conf (network security services (NSS) server
# configuration)
```

```

#
# This file contains sample configuration parameters for the NSS server.
# The search order used by the NSS server to locate the initial
# configuration file is (highest priority listed first):
#
# 1) The name of a file or MVS data set specified by the NSSD_FILE
# environment variable.
# 2) /etc/security/nssd.conf
#
# Some parameters may be dynamically modified after the
# NSS server has been started. The parameters that are
# dynamically modifiable are noted below.
#
# To dynamically modify the NSS server's configuration parameters
# first edit the configuration file and then issue the modify command
# (while the NSS server is running). This causes the NSS server to
# re-read the configuration file.
#
# Example: MODIFY NSSD,REFRESH
# Note: NSSD is the NSS server procedure name.
#
# After the NSS server has been started, a different configuration
# file can be specified by using the modify command with the FILE
# parameter. This allows modifiable parameters to be
# dynamically altered while the NSS server is running. Note that
# the parameter values modified in this fashion are not
# persistent. To make the changes persistent, edit the configuration
# file that is located at NSS server initialization time according
# to the search order described previously.
#
# Example: MODIFY NSSD,REFRESH,FILE='/etc/security/nssd.conf2'
# Note: NSSD is the NSS server procedure name.
#
# See the IP System Administrator's Commands book for more information
# about the modify command.
#
# See the IP Configuration Reference book for more information about
# the individual parameters.
#
# Blank lines, empty lines and lines beginning with the '#' char as the
# first non-space character are ignored.
# -----
#
# The NssConfig statement contains parameters that apply globally
# across all supported disciplines.

NssConfig
{
# Port portNumber                                (dynamically modifiable)
# This is the TCP port to which the NSS server will bind.
# Default: 4159
Port 4159

# SyslogLevel 0-255                                (dynamically modifiable)
# Specifies the level of logging to obtain from the NSS server.
# To specify a combination of log levels, add the level numbers.
# The supported levels are:
# 0 - NSS_SYSLOG_LEVEL_NONE - Disable NSS server syslog messages
# 1 - NSS_SYSLOG_LEVEL_MINIMUM - Minimal NSS server syslog messages
# 2 - NSS_SYSLOG_LEVEL_VERBOSE - Include cascaded internal error
#                               messages (for IBM service)
# 4 - NSS_SYSLOG_LEVEL_CERTINFO - Include info about certificate
#                               cache
# 8 - NSS_SYSLOG_LEVEL_CLIENTLIFECYCLE - Include info about client
#                               lifecycle
# 16 - NSS_SYSLOG_LEVEL_SAF_ACCESS_INFO - Include info about SAF
#                               access operations

# KeyRing userid/ringname                        (dynamically modifiable)
# The NSS server attempts to open the configured key ring during
# startup. The key ring is used throughout the IPSec and XMLAppliance
# disciplines to locate certificates and/or private keys to be used for
# centralized cryptographic services.
# When using a key ring owned by the NSS server, specify only the
# ringname value. When using a key ring owned by another user, specify
# the ring name as a userid/ringname value.
# There is no default value. If KeyRing is not specified, then the

```

```

# NSS server cannot supply certificate services.
# KeyRing nssd/keyring

# Discipline disciplineName Enable | Disable      (dynamically modifiable)
# Specifies a discipline that is enabled or disabled by the NSS server.
# Supported disciplines are:
#   IPSec -
#     Includes the IPSec certificate service and IPSec network
#     management service. The default for the IPSec discipline is
#     'Enable'.
#   XMLAppliance -
#     Includes the XMLAppliance SAF access service, XMLAppliance private
#     key service, and XMLAppliance certificate service. The default for
#     the XMLAppliance discipline is 'Enable'.
# Default: IPSec Enable
# Default: XMLAppliance Enable
Discipline IPSec Enable
Discipline XMLAppliance Enable
}

# The IPSecDisciplineConfig statement contains parameters that apply
# to only the IPSec discipline.

IPSecDisciplineConfig
{
# FIPS140 Yes | No                                (non-refreshable)
# Specifies whether the NSS server should perform cryptographic
# operations for the IPSec Discipline by invoking cryptographic modules
# that are compliant with Federal Information Processing Standard (FIPS)
# publication 140-2's Level 1 security requirements.
# Default: No
FIPS140 No

# URLLCacheInterval minutes                        (dynamically modifiable)
# Specifies the maximum amount of time in minutes that data retrieved
# from an HTTP server will be cached before an attempt to reload the
# data is made. If minutes is specified as 0 then data retrieved from
# HTTP servers will not be cached.
# Default: 10080
URLCacheInterval 10080

# CertificateURL certlabel url                     (dynamically modifiable)
# Maps a certificate (specified by certlabel) to a URL which identifies
# a file on an HTTP server that contains a DER-encoded representation
# of the certificate. Zero or more of these mappings may be specified.
# Note that this keyword only applies to network security clients that
# are using the IPSec certificate service in support of IKE version 2
# Phase 1 SA negotiations.
# There is no default value.
# CertificateURL CACert1 http://mycompany.com/ca_cert1.der

# CertificateBundleURL certlabel url               (dynamically modifiable)
# Maps a certificate (specified by certlabel) to a URL which identifies
# a file on an HTTP server that contains an x509 certificate bundle
# pertaining to the certificate. Zero or more of these mappings may be
# specified. Note that this keyword only applies to network security
# clients that are using the IPSec certificate service in support of IKE
# version 2 Phase 1 SA negotiations.
# There is no default value.
# CertificateBundleURL CACert2 http://mycompany.com/certbundle2.bnd1
}

```

Figure 16. NSS server configuration file sample

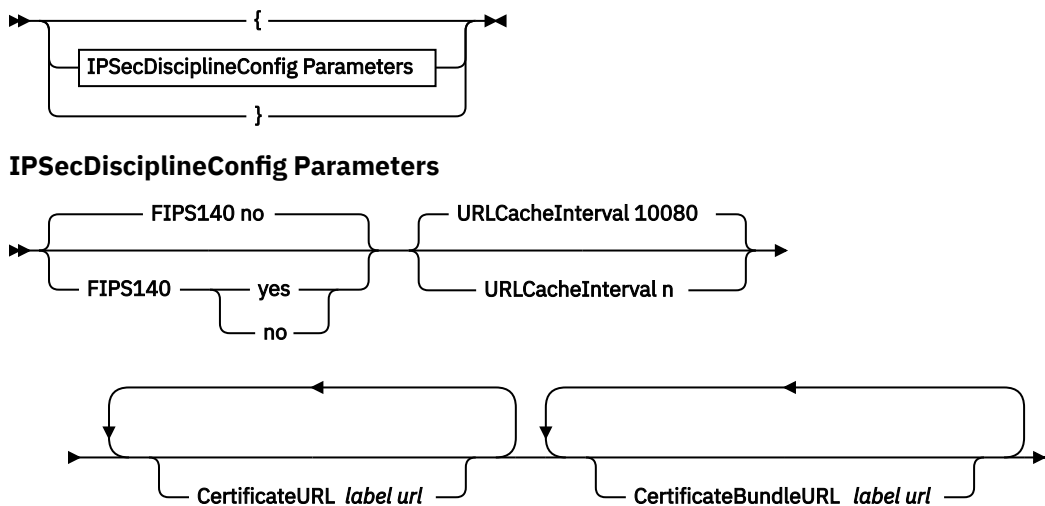

IPSecDisciplineConfig statement

The IPSecDisciplineConfig statement contains parameters that apply to the IPSec discipline only. If more than one IPSecDisciplineConfig statement is coded, the last one is used. If a parameter within the IPSecDisciplineConfig statement is specified more than once, the value from the last one is used.

Syntax

➡ IPSecDisciplineConfig — Braces & Parms on Separate Lines ➡

Braces & Parms on Separate Lines

Parameters

FIPS140 Yes | No

Specifies whether the NSS server should perform cryptographic operations by invoking cryptographic modules that are designed to meet the Level 1 security requirements documented in the Federal Information Processing Standard (FIPS) publication 140 (FIPS 140).

yes

Perform all IPSec discipline cryptographic operations using cryptographic modules that are designed to meet FIPS 140 requirements. When the value of yes is specified, the NSS server is running in FIPS 140 mode.

no

NSS server might perform some cryptographic operations using cryptographic modules that do not adhere to the FIPS 140 requirements. When the value of no is specified, the NSS server is not running in FIPS 140 mode.

Requirement: ICSF must be active before starting the NSS server when FIPS140 YES is specified. For information about configuring ICSF to support FIPS 140-2, see [Operating in compliance with FIPS 140-2 in z/OS Cryptographic Services ICSF Writing PKCS #11 Applications](#).

Rule: If the FIPS140 parameter is modified while the NSS server is running it will not take effect until the NSSD is restarted. Attempts to modify the value while the NSS server is running are ignored and a warning message is issued.

Tip: Enabling FIPS 140 mode provides a higher degree of assurance of the integrity of the cryptographic modules that the NSS server uses, including ICSF and System SSL. However, enabling FIPS 140 mode might require additional setup and configuration, it will restrict the available set of cryptographic algorithms, and it might result in a reduction in performance. See [Cryptographic standards and FIPS 140 in z/OS Communications Server: IP Configuration Guide](#) for more information.

URLCacheInterval *minutes*

Specifies the maximum amount of time in minutes that data retrieved from an HTTP server is not cached before an attempt to reload the data is made. If 0 is specified for the *minutes* value, then data retrieved from an HTTP server is not cached. The default value is 10080 which is one week. Valid values are 0-999999.

Tip: [Table 24 on page 412](#) shows when cached data must be reloaded.

Table 24. Cached data events that cause a reload

Cached data	Events that cause a reload
Certificate Data	<p>The following events cause a reload:</p> <ul style="list-style-type: none"> • The Validity notAfter time in the certificate is reached • The URLCacheInterval is reached • The NSSD MODIFY REFRESH command is issued
Certificate Bundle Data	<p>The following events cause a reload:</p> <ul style="list-style-type: none"> • The Validity notAfter time in any certificate in the bundle is reached • The nextUpdate time in any CRL in the bundle is reached • The URLCacheInterval is reached • The NSSD MODIFY REFRESH command is issued
Certificate Revocation Data	<p>The following events cause a reload:</p> <ul style="list-style-type: none"> • The nextUpdate time in the CRL is reached • The URLCacheInterval is reached • The NSSD MODIFY REFRESH command is issued

CertificateURL *label url*

The *label* is the label of a certificate on the key ring specified by the KeyRing parameter. If this label value contains imbedded blanks, then the value must be enclosed in double quote characters ("). Empty ("") and blank (" ") label names are not allowed. Any leading or trailing blanks within the double quotes will be ignored (for example, " label name " is treated as "label name"). If the string also contains a double quote character, then the imbedded double quote character must be coded as a sequence of two such characters (""). For example, the label in the following statement contains both imbedded blanks and imbedded double quotes:

```
CertificateURL    "my ""new"" certificate"    http://xyz.edu/cert51
```

The *url* is an HTTP based URL identifying a file on an HTTP server that contains the DER encoded representation of the certificate identified by *label*. The file should not contain the private key associated with the certificate. See [Creating certificate bundles in z/OS Communications Server: IP Configuration Guide](#) for additional details.

Rule: If the same label is specified on multiple CertificateURL statements only the last CertificateURL statement for that label is used.

Tip: This keyword is applicable only to network security clients utilizing certificate services during an IKE version 2 Phase 1 SA negotiation.

CertificateBundleURL *label url*

The *label* value is the label of a certificate on the key ring specified by the KeyRing parameter. If this label value contains imbedded blanks, then the value must be enclosed in double quote characters ("). Empty ("") and blank (" ") label names are not allowed. Any leading or trailing blanks within the double quotes will be ignored (for example, " label name " is treated as "label name"). If the string also contains a double quote character, then the imbedded double quote character must be coded

as a sequence of two such characters ("""). For example, the label in the following statement contains both imbedded blanks and imbedded double quotes:

```
CertificateBundleURL    "my ""new"" certificates"    http://xyz.edu/certbundle
```

The *url* is an HTTP based URL identifying a file on an HTTP server that contains an x509 certificate bundle pertaining to the certificate identified by *label*. The z/OS UNIX certbundle command may be used to create an x509 certificate bundle. See [Creating certificate bundles in z/OS Communications Server: IP Configuration Guide](#) for additional details.

Rules:

- If the same label is specified on multiple CertificateBundleURL statements, only the last CertificateBundeURL statement for that label is used.
- If the same label is specified on both a CertificateURL statement and CertificateBundleURL statement, the statement specified last is used.

Tip: This keyword is applicable only to network security clients utilizing certificate services during an IKE version 2 Phase 1 SA negotiation.

NssConfig statement

The NssConfig statement contains parameters that apply globally to the NSS server and all supported disciplines. If more than one NssConfig statement is coded, the parameters coded within all the statements are combined as if they had all been coded under one NssConfig statement. If a parameter within the NssConfig statement is specified more than once, the value from the last one is used.

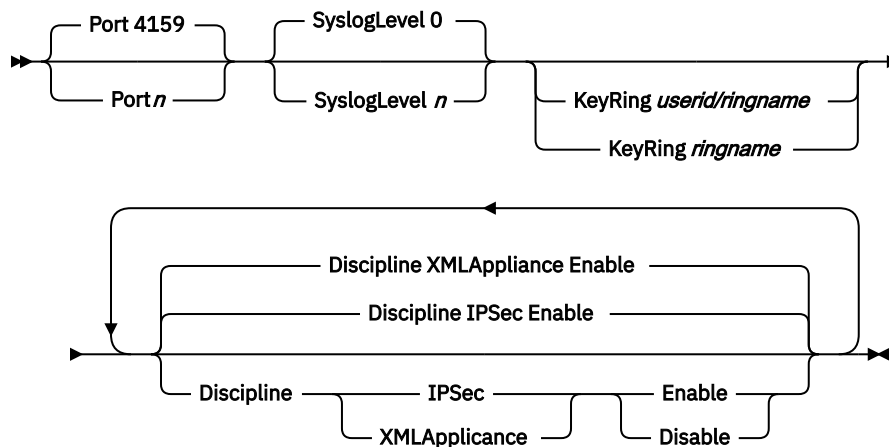

Syntax

➤ NssConfig — Braces & Parmns on Separate Lines ➤

Braces & Parmns on Separate Lines

NSSConfig Parameters

Parameters

Port *n*

The TCP port that the NSS server binds to. All NSS clients must connect to the server through this port.

The default value is 4159. Valid values are in the range 1 - 65535. Use the MODIFY NSSD,REFRESH command to change the value of this parameter. When the TCP port is changed, existing connections remain open, but all new client connections must come through the new port.

Tip: The NSS server binds to INADDR_ANY. Configuring NSS clients to connect to the NSS server on a dynamic VIPA might increase availability of the NSS server. See [NSS server failover considerations in z/OS Communications Server: IP Configuration Guide](#) for more information.

SyslogLevel *level*

Specifies the level of logging to be obtained from the NSS server. The following levels are supported:

0 - NSS_SYSLOG_LEVEL_NONE

Disable NSS server syslog messages.

1 - NSS_SYSLOG_LEVEL_MINIMUM

Minimal NSS daemon syslog output.

2 - NSS_SYSLOG_LEVEL_VERBOSE

Include cascaded internal error messages (for IBM service).

4 - NSS_SYSLOG_LEVEL_CERTINFO

Include information about certificate cache.

8 - NSS_SYSLOG_LEVEL_CLIENTLIFECYCLE

Include information about client lifecycle (connect, update, and disconnect).

16 - NSS_SYSLOG_LEVEL_SAF_ACCESS_INFO

Include information about SAF access operations.

32

Reserved

64

Reserved

128

Reserved

These levels can be added together to create a cumulative logging effect.

Use the MODIFY NSSD,REFRESH command to change this value. The default value is 1.

Rules:

- The default SyslogLevel is in effect until the parameter is read from the configuration file.
- Any level higher than 1 automatically includes 1.

KeyRing *ringname* | *userid/ringname*

The owning user ID and ring name used by the NSS server when you are creating and verifying signatures on behalf of a NSS client. When using a key ring owned by a user ID other than the NSS server user ID, *userid* must be specified. However, even if the keyring is owned by the NSS server's user ID, it is still helpful to specify *userid* to simplify certificate-related problem diagnosis. There is no default value. If KeyRing is not specified, then the NSS server cannot supply certificate services.

Restriction: The NSS server does not support PKCS #11 Tokens for the KeyRing parameter.

Use the MODIFY NSSD,REFRESH command to change this value.

Discipline *discipline* Enable | Disable

Specifies that a discipline is enabled or disabled by the NSS server. Valid disciplines are:

IPSec

Includes the IPSec certificate service and IPSec remote management service. The default for the IPSec discipline is Enable.

XMLAppliance

Includes the XMLAppliance SAF access service, the XMLAppliance certificate service, and the XMLAppliance private key service. The default for the XMLAppliance discipline is Enable.

Use the MODIFY NSSD, REFRESH command to change which disciplines are enabled or disabled, as follows:

Enabling a discipline

If, during refresh processing, the NSS server detects a Discipline statement that has been added or modified with the Enable keyword, the NSS server enables the required services to allow NSS clients to connect to the indicated discipline.

Disabling a discipline

If, after a refresh, a Discipline statement was modified with the Disable keyword, then connections for all NSS clients of the indicated discipline are removed and services for the indicated discipline are disabled. The NSS server prevents new clients from connecting to the indicated discipline.

Chapter 10. Defense Manager daemon

The Defense Manager daemon (DMD) is an integral part of defensive filtering. The z/OS UNIX **ipsec** command provides the user interface to add, update, delete, and display defensive filters. The DMD sits between the z/OS UNIX **ipsec** command and the TCP/IP stacks. The DMD manages the installation of defensive filters into the TCP/IP stacks. One instance of the DMD manages all stacks on the z/OS image. The DMD must be active for defensive filters to be added, updated, or deleted. For more information about defensive filtering, see [z/OS Communications Server: IP Configuration Guide](#). For more information about the z/OS UNIX **ipsec** command, see [z/OS Communications Server: IP System Administrator's Commands](#).

This topic contains the following information about the DMD:

- [“Starting the DMD using z/OS UNIX \(optional\)” on page 417](#)
- [“The Defense Manager daemon cataloged procedure \(optional\)” on page 417](#)
- [“DMD environment variables” on page 418](#)
- [“DMD configuration file statements” on page 420](#)

Starting the DMD using z/OS UNIX (optional)

If the DMD is to be started from the z/OS UNIX shell, use the following syntax:

➡ dmd ➡

Tip: When you are starting the DMD from the z/OS UNIX shell, set the environment variable `_BPX_JOBNAME` so that you can use a specific job name with the STOP or MODIFY console commands. For more information about `_BPX_JOBNAME`, see [z/OS UNIX System Services Planning](#).

The Defense Manager daemon cataloged procedure (optional)

If the DMD is to be started by a procedure, update the cataloged procedure, DMD, by copying the sample in SEZAINST(DMD) to your system or recognized PROCLIB. Specify the DMD parameters and change the data set names that are appropriate for your local configuration. See SEZAINST(EZARACF) for external security manager considerations for started procedures. After you have started the DMD procedure, you can specify a different DMD configuration file by using the MODIFY command with the FILE parameter. For example:

```
MODIFY DMD,REFRESH,FILE='/etc/security/dm.conf2'
```

```

//DMD PROC
//*
//* IBM Communications Server for z/OS
//* SMP/E distribution name: EZADMD
//*
//* 5650-ZOS Copyright IBM Corp. 2008, 2013
//* Licensed Materials - Property of IBM
//* Status = CSV2R1
//*
//*
//DMD EXEC PGM=DMD,REGION=0K,TIME=NOLIMIT,
// PARM='ENVAR("_CEE_ENVFILE_S=DD:STDENV")/'
//*
//* Provide environment variables to run with the desired
//* configuration. As an example, the data set or file specified by
//* STDENV could contain:
//*
//* DMD_FILE=/etc/security/dmd.conf
//* DMD_CTRACE_MEMBER=CTIDMD00
//* DMD_PIDFILE=/var/dm/dmd.pid
//* DMD_CODEPAGE=IBM-1047
//*
//* If you want to include comments in the data set or
//* z/OS UNIX file, specify the _CEE_ENVFILE_COMMENT
//* environment variable as the first environment variable
//* in the data set or file. The value specified for
//* the _CEE_ENVFILE_COMMENT variable is the comment character.
//* For example, if you want to use the pound sign, #, as
//* the comment character, specify this as the first
//* statement:
//* _CEE_ENVFILE_COMMENT=#
//*
//* For information on the above environment variables, refer to the
//* IP Configuration Reference.
//*
//STDENV DD DUMMY
//* Sample MVS data set containing environment variables:
//*STDENV DD DSN=TCPIP.DMD.ENV(DMD),DISP=SHR
//* Sample file containing environment variables:
//*STDENV DD PATH='/etc/security/dmd.env',PATHOPTS=(ORDONLY)
//*
//* Output written to stdout and stderr goes to the data set or
//* file specified with SYSPRINT or SYSOUT, respectively.
//SYSPRINT DD SYSOUT=*
//SYSOUT DD SYSOUT=*

```

Figure 17. DMD cataloged procedure

DMD environment variables

Table 25 on page 419 provides a list of environment variables used by the DMD that can be tailored to a particular installation.

Table 25. Defense Manager daemon (DMD) environment variables

Environment variable	Description	Any specific coding rules
DMD_CODEPAGE	Used by the DMD to specify the EBCDIC code page to be used for the configuration file. The default code page is IBM-1047.	<p>The following code pages are supported:</p> <ul style="list-style-type: none"> • IBM-037 • IBM-273 • IBM-274 • IBM-275 • IBM-277 • IBM-278 • IBM-280 • IBM-281 • IBM-282 • IBM-284 • IBM-285 • IBM-297 • IBM-500 • IBM-871 • IBM-1047 • IBM-1140 • IBM-1141 • IBM-1142 • IBM-1143 • IBM-1144 • IBM-1145 • IBM-1146 • IBM-1147 • IBM-1148 • IBM-1149 <p>Example:</p> <pre>DMD_CODEPAGE=IBM-1141</pre>
DMD_FILE	Used by the DMD in the search order for the DMD configuration file. For details about the search order used for locating this configuration file, see “TCP/IP configuration data sets” on page 1.	<p>Examples:</p> <pre>DMD_FILE=/etc/security/dmd.conf</pre> <pre>DMD_FILE=// 'SYS1.TCPPARMS(DMDCONF) '</pre>

Table 25. Defense Manager daemon (DMD) environment variables (continued)		
Environment variable	Description	Any specific coding rules
DMD_PIDFILE	Used by the DMD in the search order for the DMD PID file. The search order for the DMD PID file is as follows: <ol style="list-style-type: none"> 1. DMD_PIDFILE environment variable 2. /var/dm/dmd.pid 	Example: <pre>DMD_PIDFILE=/var/dm/dmd.pid</pre>
DMD_CTRACE_MEMBER	Used by the DMD to specify the name of a parmlib member that contains default CTRACE settings. The DMD_CTRACE_MEMBER environment variable is read by the DMD only during initialization. Changes to the DMD_CTRACE_MEMBER after DMD initialization have no effect.	If not defined, the default value used by the DMD is CTIDMD00. Example: <pre>DMD_CTRACE_MEMBER=CTIDMD00</pre>

DMD configuration file statements

The DMD configuration file contains parameters that define the behavior of the daemon. These parameters are contained in two statement types, DMConfig and DmStackConfig.

If a configuration error is detected during startup, the DMD logs the error and exits. If a configuration error is detected during a dynamic refresh, the entire refresh is rejected, the error is logged, and the DMD continues to run with the old configuration values.

The DMD uses the following search order to locate the configuration file:

1. The name of a file or MVS data set specified by the DMD_FILE environment variable
2. /etc/security/dmd.conf

All DMD configuration file statements are optional. An empty configuration file is permitted, but if no DmStackConfig statements are defined, no stacks are supported.

DmConfig statement

This statement contains configuration information for the DMD. Only one instance of the DmConfig statement can be included in the configuration file. If there are multiple instances of the DmConfig statement, an error is generated.

Syntax

►► DmConfig — Braces & Params on Separate Lines ►►

Braces & Params on Separate Lines

```

►► {
  DmConfig Parameters
}

```

DmConfig Parameters

Parameters

SyslogLevel *n*

Specifies the level of logging to obtain from the Defense Manager daemon. The following levels are supported:

0 - DM_SYSLOG_LEVEL_NONE

Disable Defense Manager syslog messages.

1 - DM_SYSLOG_LEVEL_MINIMUM

Minimal Defense Manager syslog output.

2 - DM_SYSLOG_LEVEL_LIFECYCLE_CLIENT

Include information about client connections and disconnections.

4 - DM_SYSLOG_LEVEL_LIFECYCLE_STACK

Include information about the cycling of stacks and the installation, deletion, or modification of defensive filters in a stack.

8 - DM_SYSLOG_LEVEL_VERBOSE

Include cascaded internal error messages (for IBM service).

16

Reserved

32

Reserved

64

Reserved

128

Reserved

You can add these levels to create a cumulative logging effect.

Use the MODIFY DMD,REFRESH command to change the SyslogLevel value.

The default value is 7.

Rules:

- The default SyslogLevel value is in effect until the parameter is read from the configuration file.
- Any level higher than 1 automatically includes 1.

DefensiveFilterDirectory *dirname*

The name of the directory in which the DMD creates a file for each stack using a copy of that stack's active defensive filters. These are binary files managed by the DMD; you must not manually modify them. This directory must exist when the DMD starts, and the DMD must have authority to create, delete, read, and write files in this directory.

This is not a refreshable parameter. Any refresh attempt fails if the new DefensiveFilterDirectory parameter value differs from the value that was used at server startup.

The default value is /var/dm/filters.

Rules:

- The binary files that DMD creates are persistent. If the DMD is restarted, the files are expected to reflect the active defensive filters in the TCP/IP stacks.

- Each stack can have a file that contains the persisted form of its active defensive filters. This file, if present, is named *active.stackname*. The name of the file that contains global defensive filters is *active._globals_*. This is a binary file managed by the DMD; do not manually modify it.
- When the DMD starts, each *active.stackname* file in the defensive filter directory is checked both for internal consistency and for consistency with the installed defensive filters in its corresponding stack (if that stack is active). If an inconsistency is detected, the file is considered to be corrupted or untrustworthy and message EZD1731I is written to syslog.
- When a defensive filter file is found to be untrustworthy, it is renamed by the DMD from *active.stackname* to *untrusted.stackname.tttttt*, where *tttttt* is the hexadecimal value of the current system timestamp as reported by the LE *time()* function. If the stack is active, any defensive filters currently in the stack are individually unaddressable by the DMD and can be referenced only by **ipsec** commands that accept or imply the ALL notation for addressing a stack's defensive filters.
- When defensive filtering is set to inactive for a stack, and if there is an *active.stackname* file for the stack, the file is renamed by the DMD from *active.stackname* to *inactive.stackname.tttttt* where *tttttt* is the hexadecimal value of the current system timestamp as reported by the language environment *time()* function. You can set defensive filtering to inactive by changing the mode of the stack on the *DmStackConfig* statement or by issuing the *MODIFY FORCE_INACTIVE* command.

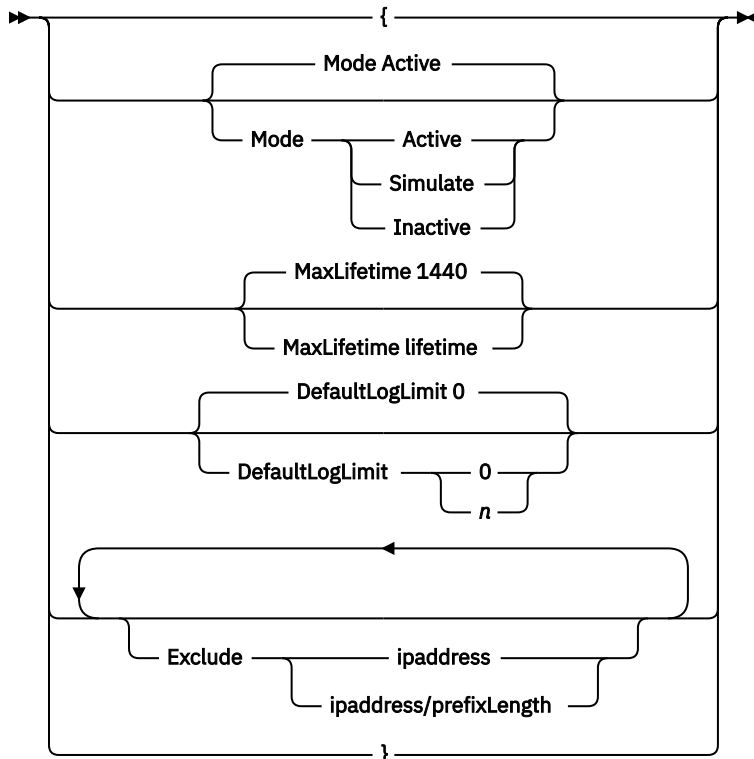

DmStackConfig statement

This statement contains the Defense Manager daemon configuration information for a single TCP/IP stack.

Syntax

➤ **DmStackConfig** — *stackname* — Braces & Params on Separate Lines ➤

Braces & Params on Separate Lines

Parameters

stackname

The name of the TCP/IP stack that is being configured for defensive filter support. This is a required parameter, and there is no default value.

Mode Active | Simulate | Inactive

Specifies the defensive filter mode for the TCP/IP stack. Possible values are:

Active

When the stack specified by the *stackname* value is active and configured for IP security, it is managed by the DMD. Each defensive filter applied to that stack operates in the mode specified for the individual defensive filter, either block or simulate. Blocking mode discards packets that match the defensive filter. Simulate mode simulates a block for packets that match the defensive filter. When a packet matches a defensive filter with a simulate mode, a message is logged to indicate that the packet would have been discarded. However, the packet is not discarded and processing continues with IP filtering. For more information about simulate block behavior, see the [z/OS Communications Server: IP Configuration Guide](#). This is the default.

Simulate

When the stack specified by the *stackname* value is active and configured for IP security, it is managed by the DMD. All defensive filters applied to that stack operate in simulate mode, overriding the mode specified for the individual filters. Simulate mode simulates a block. When a packet matches a defensive filter and the mode is simulate, a message is logged to indicate that the packet would have been discarded. However, the packet is not discarded and processing continues with IP filtering. For more information about simulate block behavior, see the [z/OS Communications Server: IP Configuration Guide](#).

Tip: Simulate mode would typically be used in a test environment.

Inactive

If the stack specified by the *stackname* value is active and configured for IP security when the DMD starts, all defensive filters are removed from that stack and also from the DMD memory. No new defensive filters are installed in the stack while the mode is set to Inactive.

Tip: Use inactive mode to disable defensive filtering for the stack. If you remove the DmStackConfig statement for the stack from the DMD configuration file, the defensive filters currently installed in the stack are not removed. Without the DmStackConfig statement, you cannot use the z/OS UNIX **ipsec** command to delete defensive filters from the stack.

Use the MODIFY DMD,REFRESH command to change this value. You can also use the MODIFY DMD,FORCE_INACTIVE,*stackname* command to change the mode to Inactive without refreshing the configuration.

Exclude

Specifies an IP address or subnet to exclude from the effects of defensive filters installed in the stack specified by the *stackname* value. Inbound packets originating from an IP address in the exclusion list are excluded from defensive filter processing. Outbound packets destined to an IP address in the exclusion list are excluded from defensive filter processing.

Tip: Defensive filters are checked before IP security filters. To ensure that an administrator is not blocked by a defensive filter, you can exclude the administrator's IP address from defensive filter processing by specifying the administrator's address on the Exclude statement.

ipaddress

Specifies a single IP address to be excluded from the effects of defensive filters. This value can be an IPv4 or IPv6 address.

ipaddress/prefixLength

Specifies a prefix address specification that indicates the applicable IP addresses to be excluded from the effects of defensive filters. The *prefixLength* value is the number of unmasked leading bits in the *ipaddress* value. The *prefixLength* value can be in the range 0 - 32 for IPv4 addresses and 0 - 128 for IPv6 addresses. An IP address matches this exclusion if its unmasked bits are identical to the defined unmasked bits.

There is a limit of 10 Exclude keywords on the DmStackConfig statement.

Use the MODIFY DMD,REFRESH command to change this value. In case of a successful refresh, the new list of exclusion addresses completely replaces the prior list of exclusion addresses.

This is an optional parameter, and there is no default value.

MaxLifetime

Specifies the maximum lifetime of a defensive filter in minutes. This value limits a defensive filter's lifetime when the defensive filter is first added or later updated. Lifetime values that exceed the MaxLifetime value are truncated to MaxLifetime minutes. Existing filters are not affected by a change to the MaxLifetime value that results from a MODIFY DMD,REFRESH operation.

lifetime

Specifies the maximum number of minutes that are allowed for a defensive filter's lifetime. Valid values are in the range 1 - 20160 (2 weeks). The default is 1440 (1 day).

DefaultLogLimit

Specifies the default log limit for defensive filters that are added to this TCP/IP stack. When a defensive filter is added and the loglimit parameter is not specified on the z/OS UNIX ipsec add command, the DefaultLogLimit value will be used. The log limit value is used to enable or disable the limiting of defensive filter match messages (EZD1721I and EZD1722I). See [filter-match logging](#) in [z/OS Communications Server: IP Configuration Guide](#) for more information.

0

Disables the limiting of defensive filter match messages. If logging is being done for this defensive filter, a message is generated for each packet that matches the defensive filter. 0 is the default.

n

Enables the limiting of defensive filter match messages. Valid values are in the range 1 - 9999. The value limits the average rate of filter-match messages generated in a 5-minute interval for a defensive filter. For example, a value of 100 limits the average rate of filter-match messages to 100 messages per 5-minute interval. A burst of up to 100 messages is allowed while maintaining the long-term average of 100 messages per 5-minute interval.

Result: The DMD installs and manages defensive filters only in TCP/IP stacks that are configured with a DmStackConfig statement in the DMD configuration file.

DMD configuration file sample

This topic shows the Defense Manager daemon configuration file sample.

```
#
# IBM Communications Server for z/OS
# SMP/E distribution path: /usr/lpp/tcpip/samples/dmd.conf
#
# 5650-ZOS Copyright IBM Corp. 2013.
# Licensed Materials - Property of IBM
# Status = CSV2R1
#
# /etc/security/dmd.conf (Defense Manager daemon configuration)
#
# This file contains sample Defense Manager daemon configuration
# parameters. The search order used by the Defense Manager daemon to
# locate the initial configuration file is (highest priority listed
# first):
#
# 1) The name of a z/OS UNIX file or z/OS dataset specified by the
#    DMD_FILE environment variable.
# 2) /etc/security/dmd.conf
#
# Some parameters are dynamically modifiable after the
# Defense Manager daemon has been started. The parameters that are
# dynamically modifiable are noted below.
#
# One way of dynamically modifying parameters is to edit
# the Defense Manager daemon configuration file after the Defense
# Manager daemon has been started and then issue a MODIFY command
# to cause the Defense Manager daemon to re-read the configuration file.
#
```

```

# Example: MODIFY DMD,REFRESH
# Note: DMD is the Defense Manager daemon procedure name.
#
# After the Defense Manager daemon has been started, a different
# configuration file can be specified by using the Modify command with
# the FILE parameter. This allows modifiable parameters to be
# dynamically altered while the Defense Manager daemon is running. Note
# that the parameter values modified in this fashion are not
# persistent. To make the changes persistent, edit the dmd.conf
# file that is located at the Defense Manager daemon initialization
# time according to the search order described previously.
#
# Example: MODIFY DMD,REFRESH,FILE='/etc/security/dmd.conf2'
# Note: DMD is the Defense Manager daemon procedure name.
#
# See the IP System Administrator's Commands book for more information
# about the modify command.
#
# See the IP Configuration Reference book for more information about
# the individual parameters.
#
# Blank lines, empty lines and lines beginning with the '#' char as the
# first non-space character are ignored.
# -----
#
DMConfig
{
# SyslogLevel 0-255 (dynamically modifiable)
#
# Specifies the level of logging to obtain from the Defense Manager
# daemon. To specify a combination of log levels, add the level numbers.
# The supported levels are:
# 0 - DM_SYSLOG_LEVEL_NONE - Disable the Defense Manager daemon syslog
#   messages
# 1 - DM_SYSLOG_LEVEL_MINIMUM - Minimal Defense Manager daemon syslog
#   output
# 2 - DM_SYSLOG_LEVEL_LIFECYCLE_CLIENT - Include info about the connect
#   and disconnect of clients.
# 4 - DM_SYSLOG_LEVEL_LIFECYCLE_STACK - Include info about the cycling
#   of stacks and the installation, deletion or modification of
#   defensive filters to the stack.
# 8 - DM_SYSLOG_LEVEL_VERBOSE - Include cascaded internal error messages
#   (for IBM service)
# 16 - reserved
# 32 - reserved
# 64 - reserved
# 128 - reserved
# Default: 7
SyslogLevel 7
#
# DefensiveFilterDirectory dirname (not dynamically modifiable)
#
# The name of the directory where the Defense Manager daemon will
# create a file for each stack with a copy of that stack's
# active defensive filters. These are binary files managed
# by the Defense Manager daemon and must not be manually modified.
# This directory must exist when the Defense Manager daemon starts and
# the Defense Manager daemon must have authority to create, delete,
# read and write files in this directory.
#
# This is not a refreshable parameter. Any REFRESH attempt
# will fail if the new value of the DefensiveFilterDirectory
# parameter differs from the value used at server startup.
# Default: /var/dm/filters
DefensiveFilterDirectory /var/dm/filters
}

#DmStackConfig TCP
{
# Mode Active|Simulate|Inactive (dynamically modifiable)
#
# This specifies the defensive filter mode for the TCP/IP stack.
#
# Valid options are:
#
# Active When stackname is active and configured for IP security,
# it will be managed by the DMD. Each defensive filter
# applied to stackname will operate in the mode specified
# for the individual defensive filter, block or simulate.
# Blocking mode will discard packets that match the defensive
# filter. Simulate mode will simulate a block for packets
# that match the defensive filter. When a packet matches a

```

```

#      defensive filter with a mode of simulate, a message will
#      be logged indicating that the packet would have been
#      discarded. However, the packet will not be discarded and
#      IP filtering will continue. For more information on
#      simulate block behavior see the IP Configuration Guide.
#      Simulate  When stackname is active and configured for IP security,
#      it will be managed by the DMD. All defensive filters
#      applied to stackname will operate in simulate mode,
#      overriding the mode specified for the individual filters.
#      Simulate mode simulates a block. When a packet matches a
#      defensive filter and the mode is simulate, a message will
#      be logged indicating that the packet would have been
#      discarded. However, the packet will not be discarded
#      and IP filtering will continue. For more information on
#      simulate block behavior see the IP Configuration Guide.
#      Tip: Simulate mode would typically be used in a test
#      environment.
#      Inactive  If stackname is active and configured for IP security
#      when the DMD starts, then all defensive filters will be
#      removed from stackname and also from the DMD memory. No
#      new defensive filters will be installed in stackname
#      while the mode is Inactive.
#      Tip: Use Inactive mode to disable defensive filtering for
#      stackname. Removing the DmStackConfig statement for
#      stackname from the DMD configuration file does not
#      remove defensive filters currently installed in
#      stackname, and without the DmStackConfig statement,
#      the z/OS UNIX ipsec command cannot delete defensive
#      filters from stackname.
#      Default: Active
#      Mode Active
#
#      MaxLifetime  lifetime (dynamically modifiable)
#
#      Valid values are 1-20160 minutes.
#
#      Maximum number of minutes allowed for a defensive filter's lifetime.
#      This value limits a defensive filter's lifetime when the defensive
#      filter is first added or later updated. Lifetime values that exceed
#      MaxLifetime are truncated to MaxLifetime minutes. Existing filters
#      are not affected by a change to MaxLifetime resulting from a
#      MODIFY DMD,REFRESH operation.
#
#      Default: 1440 minutes (one day)
#      MaxLifetime 1440
#
#      DefaultLogLimit  loglimit (dynamically modifiable)
#
#      Valid values are 0-9999.
#
#      Default log limit for defensive filters added to this TCP/IP stack.
#      When a defensive filter is added and the loglimit parameter is not
#      specified on the add command, the DefaultLogLimit value will be used.
#      The log limit value is used to enable or disable limiting of
#      defensive filter match messages (EZD1721I and EZD1722I).
#
#      Valid values are:
#
#      0 - Disables limiting of defensive filter match messages. If logging
#      is being done for this defensive filter, a message is generated
#      for each packet that matches the defensive filter.
#      1-9999 - Enables limiting of defensive filter match messages. The
#      value limits the average rate of defensive filter match
#      messages generated in a 5-minute interval. For example, a
#      value of 100 would limit the average rate of defensive
#      filter match messages to 100 messages per 5 minutes,
#      allowing up to 100 messages to be issued in a burst, while
#      maintaining the long-term average.
#
#      Default: 0
#      DefaultLogLimit 0
#
#      Exclude ipaddress | ipaddress/prefixLength (dynamically modifiable)
#
#      Specifies an IP address or subnet to exclude from the effects of
#      defensive filters. The ipaddress can be an IPv4 address or an IPv6
#      address. Hostnames are not supported.
#
#      There is a limit of 10 Exclude keywords on the DmStackConfig
#      statement.
#
#      In the case of a successful REFRESH, the new list of exclusion

```

```
# addresses will completely replace the prior list of exclusion
# addresses.
#
# Default: None.
#Exclude 9.29.4.25
#Exclude 9.29.4.26
#}
```

Figure 18. DMD configuration file sample

Chapter 11. OMPROUTE

This topic includes the following information:

- “Starting OMPROUTE using z/OS UNIX (optional)” on page 429
- “OMPROUTE cataloged procedure (optional)” on page 429
- “OMPROUTE parameters” on page 430
- “OMPROUTE environment variables” on page 431
- “OMPROUTE configuration file statements” on page 433

Starting OMPROUTE using z/OS UNIX (optional)

If OMPROUTE is to be started from the z/OS shell, use the following syntax:

➤ **omproute** 

OMPROUTE cataloged procedure (optional)

If OMPROUTE is to be started by a procedure, update the cataloged procedure OMPROUTE by copying the sample in SEZAINST(OMPROUTE) to your system or recognized PROCLIB. Specify OMPROUTE parameters and change the data set names to suit your local configuration.

```
/*
/* TCP/IP for MVS
/* SMP/E Distribution Name: EZBORPRC
/* /*      5650-ZOS Copyright IBM Corp. 1998, 2015
/*      Licensed Materials - Property of IBM
/*      This product contains "Restricted Materials of IBM"
/*      All rights reserved.
/*      US Government Users Restricted Rights -
/*      Use, duplication or disclosure restricted by
/*      GSA ADP Schedule Contract with IBM Corp.
/*      See IBM Copyright Instructions.
/*
/*OMPROUTE PROC
/*OMPROUTE EXEC PGM=OMPROUTE,REGION=10M,TIME=NOLIMIT,
/* PARM=('ENVAR("_CEE_ENVFILE_S=DD:STDENV")/')
/*
/* Example of start parameters to OMPROUTE:
/*
/* PARM=('ENVAR("_CEE_ENVFILE_S=DD:STDENV")/-t1 -6t1')
/*
/*      Provide environment variables to run with the desired
/*      stack and configuration. As an example, the file
/*      specified by STDENV could have these lines in it:
/*
/*      RESOLVER_CONFIG='SYS1.TCPPARMS(TCPDATA2)'
/*      OMPROUTE_FILE=/u/usernnn/config.tcpcs2
/*      OMPROUTE_DEBUG_FILE=/tmp/logs/omproute.debug
/*      OMPROUTE_IPV6_DEBUG_FILE=/tmp/logs/omprout6.debug
/*      OMPROUTE_DEBUG_FILE_CONTROL=1000,5
/*
/*      For information on the above environment variables,
/*      refer to the IP CONFIGURATION GUIDE.
/*
/*      When using _CEE_ENVFILE with an MVS data set, the data set
/*      must be allocated with RECFM=V. To use a RECFM=F data set, _CEE_ENVFILE_S
/*      should be used to prevent the environment variable values from being padded
/*      with blanks.
/*      If you want to include comments in the data set or
/*      z/OS UNIX file, specify the _CEE_ENVFILE_COMMENT
/*      environment variable as the first environment variable
/*      in the data set or file. The value specified for the
```

```

/*      _CEE_ENVFILE_COMMENT variable is the comment character.
/*      For example, if you want to use the semicolon sign, ;,
/*      as the comment character, specify this as the first
/*      statement:
/*      _CEE_ENVFILE_COMMENT=;
/*
//STDENV DD PATH='/u/usernnn/envcs2',
//      PATHOPTS=(ORDONLY)
/*
/*      The stdout stream may be redirected to a HFS file as
/*      shown below.
/*      The PATHOPTS OTRUNC option will clear the stdout file
/*      every time OMPROUTE is started. If you want to retain
/*      previous stdout information, change it to OAPPEND.
/*
//SYSPRINT DD SYSOUT=*
/**SYSPRINT DD PATH='/tmp/omproute.stdout',
/*      PATHOPTS=(OWRONLY,OCREAT,OTRUNC),
/*      PATHMODE=(SIRUSR,SIWUSR,SIRGRP,SIWGRP)
/*
/*      The stderr stream may be redirected to a HFS file as
/*      shown below.
/*      The PATHOPTS OTRUNC option will clear the stderr file
/*      every time OMPROUTE is started. If you want to retain
/*      previous stderr information, change it to OAPPEND.
/*
//SYSOUT DD SYSOUT=*
/**SYSOUT DD PATH='/tmp/omproute.stderr',
/*      PATHOPTS=(OWRONLY,OCREAT,OTRUNC),
/*      PATHMODE=(SIRUSR,SIWUSR,SIRGRP,SIWGRP)
/*
//CEEDUMP DD SYSOUT=*,DCB=(RECFM=FB,LRECL=132,BLKSIZE=132)

```

Figure 19. OMPROUTE cataloged procedure

Restriction: When using `_CEE_ENVFILE` with an MVS data set, the data set must be allocated with `RECFM=V`. To use a `RECFM=F` data set, `_CEE_ENVFILE_S` should be used to prevent the environment variable values from being padded with blanks.

OMPROUTE parameters

-tn

External tracing level for OMPROUTE initialization and IPv4 routing protocols, where *n* is a supported trace level. The following values are supported:

1. Informational messages
2. Formatted packet trace and informational messages

-dn

Internal debugging level for OMPROUTE initialization and IPv4 routing protocols, where *n* is a supported debug level. This parameter is intended for service, as it provides information needed for debugging problems.

-sn

Internal subagent debugging level, where *n* is a supported debug level. This parameter is intended for service, as it provides information needed for debugging problems.

-6tn

External tracing level for IPv6 routing protocols, where *n* is a supported trace level. The following values are supported:

1. Informational messages
2. Formatted packet trace and informational messages

-6dn

Internal debugging level for IPv6 routing protocols, where *n* is a supported debug level. This parameter is intended for service, as it provides information needed for debugging problems.

For more information about the `-dn`, `-6dn`, and `-sn` parameters, see [z/OS Communications Server: IP Diagnosis Guide](#).

IBM Health Checker for z/OS can be used to check whether the total number of indirect routes in a TCP/IP stack routing table exceeds a maximum threshold. When this threshold is exceeded, OMPROUTE and the TCP/IP stack may potentially experience high CPU consumption from routing changes. A large routing table is considered to be inefficient in network design and operation. For more details about IBM Health Checker for z/OS, see [z/OS Communications Server: IP Diagnosis Guide](#) and [IBM Health Checker for z/OS User's Guide](#).

OMPROUTE environment variables

Table 26 on page 431 provides a list of environment variables used by OMPROUTE and that be tailored to a particular installation:

Table 26. OMPROUTE environment variables		
Environment variable	Description	Any specific coding rules (or a link to syntax)
RESOLVER_CONFIG	The RESOLVER_CONFIG variable is used by OMPROUTE to locate the resolver configuration file.	For more information about OMPROUTE's use of the resolver configuration file, see z/OS Communications Server: IP Configuration Guide . For more information about the RESOLVER_CONFIG environment variable, see z/OS UNIX System Services Planning .
OMPROUTE_CTRACE_MEMBER	The OMPROUTE_CTRACE_MEMBER variable is used by OMPROUTE to specify the name of the parmlib member containing CTRACE default settings. Use this environment variable to set different CTRACE options and buffer sizes for multiple OMPROUTE instances.	If not defined, the default value is CTIORA00.
OMPROUTE_DEBUG_FILE	The OMPROUTE_DEBUG_FILE variable is used by OMPROUTE to override the debug output destination for IPv4 dynamic routing protocols and for processing common to both IPv4 and IPv6 routing protocols. For more information about using this environment variable, see z/OS Communications Server: IP Configuration Guide .	Restriction: Ensure that the two debug file names are not identical in the characters up to the first period (.). This prevents problems when the initial debug files fill up and OMPROUTE tries to rename them, using the name up to the first period (.) with a sequence number substituted for the rest of the name. For more information about using this environment variable, see z/OS Communications Server: IP Configuration Guide .

Table 26. OMPROUTE environment variables (continued)

Environment variable	Description	Any specific coding rules (or a link to syntax)
OMPROUTE_IPV6_DEBUG_FILE	The OMPROUTE_IPV6_DEBUG_FILE variable is used by OMPROUTE to override the debug output destination for IPv6 routing protocols.	<p>Restriction: Ensure that the two debug file names are not identical in the characters up to the first period (.). This prevents problems when the initial debug files fill up and OMPROUTE tries to rename them, using the name up to the first period (.) with a sequence number substituted for the rest of the name.</p> <p>For more information about using this environment variable, see z/OS Communications Server: IP Configuration Guide.</p>
OMPROUTE_DEBUG_FILE_CONTROL	The OMPROUTE_DEBUG_FILE_CONTROL variable is used to specify the size and quantity of the files produced as a result of the OMPROUTE_DEBUG_FILE and OMPROUTE_IPV6_DEBUG_FILE environment variable.	For more information about using this environment variable, see z/OS Communications Server: IP Configuration Guide .
OMPROUTE_FILE	Used by OMPROUTE in the search order for the OMPROUTE configuration file. It uses the value as the name of an MVS data set or z/OS UNIX file to access the configuration data.	For more information about using this environment variable, see z/OS Communications Server: IP Configuration Guide .
OMPROUTE_OPTIONS	The OMPROUTE_OPTIONS variable is ignored and will be retired in a future release.	<p>The only supported parameter is hello_hi, which is ignored and will be retired in a future release.</p> <p>The behavior, which is previously provided only when hello_hi is coded, is now always enabled. The hello_hi option is used to enforce OMPROUTE to process the hello packets at a higher priority than other updates. The hello_hi option also helps prevent adjacencies from failing when OMPROUTE is being flooded with protocol packets.</p>
SNMP_PORT	Specifies the port to which a DPI subagent directs a connection query. The default is 161 (the default port on which the SNMP agent listens for queries).	None

Table 26. OMPROUTE environment variables (continued)		
Environment variable	Description	Any specific coding rules (or a link to syntax)
TMPDIR	Holds the name of a directory where shell commands are free to create temporary working files. If TMPDIR is not defined, the default directory is /tmp.	For more information about using this environment variable, see z/OS UNIX System Services Command Reference .

OMPROUTE configuration file statements

Statements in the OMPROUTE configuration file have the following syntax:

```
type tag=value tag=value.. .. .;
where:
type           Specifies what is to be configured
tag=value      Specifies a parameter and its associated value.
type=value     Used for statements that have only a single parameter.
```

Rules: The following list shows the syntax rules for the OMPROUTE configuration statements:

- Types, tags, and values can be specified in mixed case.
- Every configuration statement, with the exception of the INCLUDE statement, must end with a semicolon (;).
- Blanks and comments are supported. Comments are identified by a semicolon in any column. Comments cannot appear within a configuration statement.
- Statements can begin in any column.
- There must be no sequence numbers in the data set or file.
- Statements with only optional operands must have at least one operand coded, even if all operands have defaults.
- You can use static system symbols in OMPROUTE configuration file statements.

A sample OMPROUTE configuration file is provided in SEZAINST(EZAORCFG).

INCLUDE statement

This statement causes configuration statements from the specified data set to be included at the point at which the INCLUDE statement is encountered in the configuration file.

Rules:

- The INCLUDE statement must be the only configuration statement on the line.
- The INCLUDE statement must not end with semicolon.
- There must be no more than 10 nested INCLUDE statements.
- You can specify static system symbols as part of the data set name.

Syntax

```
➤ INCLUDE ——— //'fully qualified MVS dataset name' —➤
              |
              | /file system absolute pathname —➤
```

Parameters

//'fully qualified MVS dataset name'

The complete name of the MVS data set that contains the OMPROUTE configuration statements. The data set can be a sequential data set or a PDS with the member name.

Requirement: The double slash (//) and beginning and ending quotation marks are required.

/file system absolute pathname

The complete name of the file system that contains the OMPROUTE configuration statements. The z/OS UNIX path name is case sensitive.

Requirement: The beginning slash (/) is required.

Guideline: If a syntax error is encountered in the final version of the configuration file after one or more INCLUDE files were processed, use debug level d1 to print a copy of the expanded configuration file to your OMPROUTE trace. This helps to identify the correct line number where the syntax error was found, as reported from the error message. For more information about [OMPROUTE traces and debug information](#), see [z/OS Communications Server: IP Diagnosis Guide](#).

OSPF configuration statements

This topic contains descriptions of the following OSPF configuration statements:

- AREA
- AS_BOUNDARY_ROUTING
- COMPARISON
- DEMAND_CIRCUIT
- OSPF
- OSPF_INTERFACE
- RANGE
- ROUTERID
- VIRTUAL_LINK

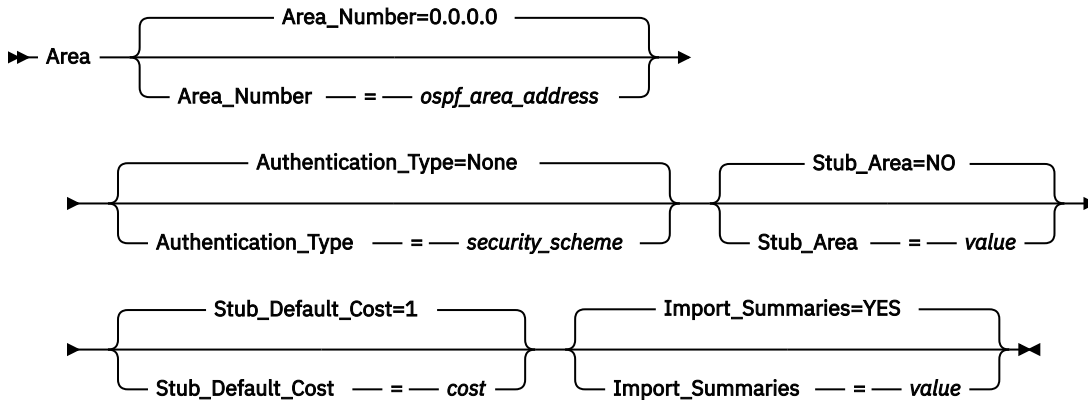

Use these statements to configure the OSPF environment for IPv4. For information about the statements used to configure IPv6 OSPF, see [“IPv6 OSPF configuration statements” on page 461](#).

See [z/OS Communications Server: IP System Administrator's Commands](#) for information about how to display configuration information.

AREA statement

Use the AREA statement to set the parameters for an OSPF area. If no areas are defined, OMPROUTE assumes that all directly attached networks belong to the backbone area (area ID 0.0.0.0).

Syntax

Parameters

Area_Number

The OSPF area number in dotted decimal.

Authentication_Type

The default security scheme to be used in the area. Valid values for authentication types are MD5, which indicates MD5 cryptographic authentication as described in Appendix D of RFC 2328; PASSWORD, which indicates a simple password; or NONE, which indicates that no authentication is necessary to pass packets. The area's default security scheme can be overridden on an interface basis by specifying the Authentication_Type keyword on OSPF_INTERFACE or VIRTUAL_LINK statements.

Stub_Area

Specifies whether this area is a stub area or not. Valid values are YES or NO.

If you specify Stub_area = YES, the area does not receive any AS external link advertisements, reducing the size of your database and decreasing memory usage for routers in the stub area. You cannot configure virtual links through a stub area. You cannot configure a router within the stub area as an AS boundary router.

You cannot configure the backbone as a stub area. External routing in stub areas is based on a default route. Each border area router attaching to a stub area originates a default route for this purpose. The cost of this default route is also configurable with the AREA statement.

Stub_Default_Cost

The cost that an OMPROUTE area border router associates with the default route that it generates into the stub area. Valid values are in the range 1 - 16 777 215.

Import_Summaries

Determines whether this stub area imports a routing summary from a neighbor area. Valid values are YES or NO.

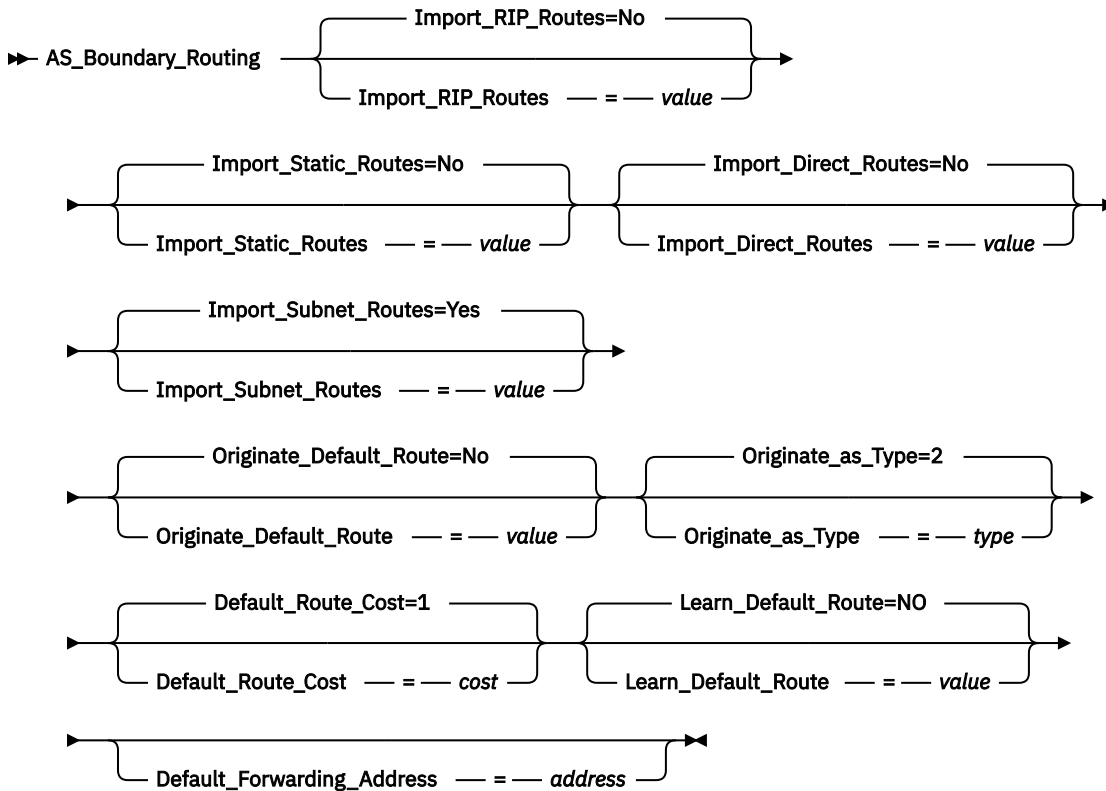

AS_BOUNDARY_ROUTING statement

Use the AS_BOUNDARY_ROUTING statement to enable the AS boundary routing capability, which allows you to import routes learned from other methods (RIP, statically configured, and direct routes) into the OSPF domain. All routes are imported as either Type 1 or Type 2 external routes, depending on what was coded on the Comparison statement. The metric type used when importing routes determines how the imported cost is viewed by the OSPF domain. When comparing Type 2 metrics, only the external cost is considered in picking the best route. When comparing Type 1 metrics, the external and internal costs of the route are combined before making the comparison.

Rules:

- This statement must be coded even if the only route you want to import is the default route (destination 0.0.0.0).
- You can import into the OSPF domain only static routes that are configured in the main route table. You cannot import static routes that are configured in a policy-based route table.

Syntax

Parameters

Import_RIP_Routes

Specifies whether routes learned by RIP are imported into the OSPF routing domain. Valid values are YES or NO.

Import_Static_Routes

Specifies whether static routes (routes defined to the TCP/IP stack using the BEGINROUTES statement) are imported into the OSPF routing domain. Valid values are YES or NO.

Import_Direct_Routes

Specifies whether direct routes are imported into the OSPF routing domain. Valid values are YES or NO.

Import_Subnet_Routes

Independent of the RIP, static, and direct routes you can choose to import, you can also configure whether or not to import subnet routes into the OSPF domain. Valid values are YES or NO.

Originate_Default_Route

Specifies whether or not this router originates an AS External default route into the OSPF domain. If YES and Default_Forwarding_Address is not also coded (or is coded to 0.0.0.0), this router advertises itself as a default router. Valid values are YES or NO.

Originate_as_Type

Specifies the external type assigned to the default route. Valid values are 1 or 2.

Default_Route_Cost

Specifies the cost that OSPF associates with the default route. Valid values are in the range 0 - 16 777 215.

Learn_Default_Route

Specifies whether OSPF learns default routes from inbound RIP or OSPF external packets when their cost is equal to or higher than the default route originated by this host. Valid values are YES or NO.

Default_Forwarding_Address

If Originate_Default_Route is YES, this optional parameter can be used to specify that this router should originate a default route on behalf of a different router. This parameter is not needed if this router is to advertise itself as the default router. It should be used only when the default router is another router that this router can route to, which is not capable of advertising an OSPF default route on its own behalf. In that case, this parameter should be set to a reachable interface IP address on the other router.

Restriction: This address must be reachable using an OSPF intra-area or inter-area route (labelled as SPF or SPIA in the RTTABLE display, or labelled as DIR but using an OSPF interface). This route could be a host, subnet, network, or default route. If no eligible route is found, the forwarding address is not included in the advertisements generated by this statement.

COMPARISON statement

Use the COMPARISON statement as an alternate method for specifying the Comparison parameter on the OSPF configuration statement. See [“OSPF statement” on page 438](#) for a description of this statement.

For additional information about the COMPARISON configuration statement, see [z/OS Communications Server: IP Configuration Guide](#).

Syntax

Parameters

Comparison

Compare to type 1 or 2 externals. Valid values are Type1 (or 1) or Type2 (or 2).

DEMAND_CIRCUIT statement

Use the DEMAND_CIRCUIT statement as an alternate method for specifying the DEMAND_CIRCUIT parameter on the OSPF configuration statement. See [“OSPF statement” on page 438](#) for a description of this statement.

Syntax

Parameters

Demand_Circuit

Valid values are YES or NO.

OSPF statement

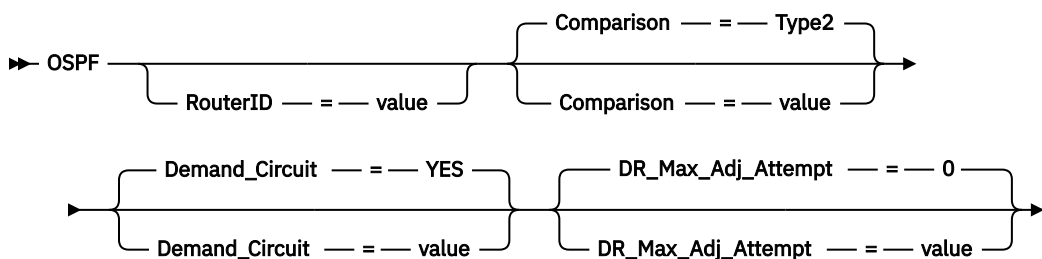

Use the OSPF statement to specify parameters that apply globally to IPv4 OSPF, either to all interfaces or to the overall OSPF autonomous system.

The following parameters can also be specified as stand-alone configuration statements:

- DEMAND_CIRCUIT
- ROUTERID
- COMPARISON

Guideline: You should use the OSPF statement for defining these parameters. If both the OSPF statement and the standalone statements are coded, the last one coded in the configuration file takes precedence.

Syntax

Parameters

RouterID

Every router in an IPv4 OSPF routing domain must be assigned a unique 32-bit router ID.

The value used for the OSPF router ID is chosen as follows:

- If this RouterID statement is specified, the value configured is used as the OSPF router ID. This value must be one of the OSPF interface IP addresses that is configured for the stack.

Rule: Loopback and reserved 0.0.0.0 addresses are not valid IP interface addresses.

- If the router ID is not configured, one of the OSPF interface addresses will be used as the OSPF router ID, provided that the interface exists in the TCPIP profile and matches the corresponding OSPF interface statement in the OMPROUTE configuration file at startup.

Result: When OMPROUTE has to assign the router ID, it does not use dynamic VIPA IP addresses. This avoidance of dynamic VIPA IP addresses cannot be guaranteed; for example, if dynamic VIPAs are the only active OSPF interfaces when OMPROUTE chooses the router ID, then one of them will be chosen.

Guideline: Because dynamic VIPAs (DVIPAs) can move between z/OS hosts, the router ID should be a physical interface or a static VIPA, not a dynamic VIPA address. To ensure an appropriate router ID, specify the router ID to OMPROUTE.

Valid values are any IPv4 dotted-decimal address that matches a configured OSPF interface.

Comparison

Tells OMPROUTE where external routes fit in the IPv4 OSPF hierarchy. OSPF supports two types of external metrics. Type 1 external metrics are equivalent to the link state metric. Type 2 external

metrics are greater than the cost of any path internal to the autonomous system. Use of type 2 external metrics assumes that routing between autonomous systems is the major cost of routing a packet, and eliminates the need for conversion of external costs to internal link state metrics. For more information about the COMPARISON configuration parameter, see [z/OS Communications Server: IP Configuration Guide](#). Valid values are Type1 (or 1) or Type2 (or 2).

Demand_Circuit

This value determines the global demand circuit setting. Coding YES enables demand circuits. Demand circuit parameters can then be coded on the OSPF_Interface statement. Valid values are Yes or No.

DR_Max_Adj_Attempt

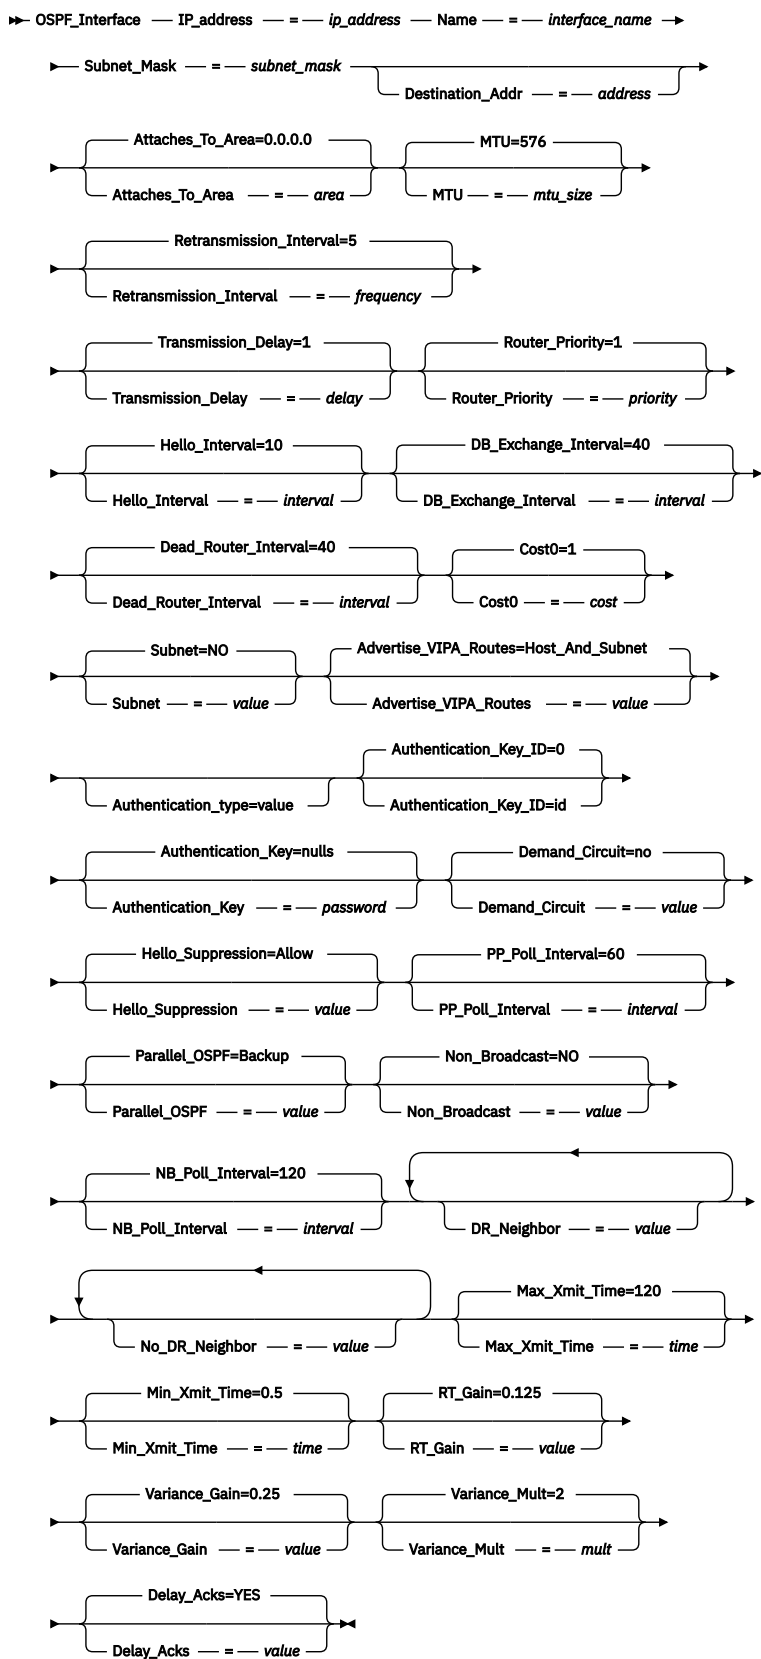

Specifies the maximum number of adjacency attempts to be used for reporting and controlling futile neighbor state loops. After the adjacency attempt count for a neighboring designated router reaches the threshold, an informational message is issued to report the problem. If a redundant interface is available that can reach the neighbor, adjacency formation is attempted over that interface. An informational message is issued to report the interface switch and adjacency formation attempt. Valid values are in the range 0 - 100. The value 0 specifies infinite retries.

For information about futile neighbor state loops, see the [Minimizing the routing responsibility of z/OS Communications Server](#) in [z/OS Communications Server: IP Configuration Guide](#). For the types of interfaces that support the futile neighbor state loop detection for OSPF, see [“Interfaces supported by OMPROUTE”](#) on page 489.

OSPF_INTERFACE statement

Use the OSPF_INTERFACE statement to set the OSPF parameters for interfaces. Replicate this statement in the configuration file for each IP interface over which OSPF operates.

Syntax

Parameters

IP_address

IP address of the local interface to be configured for OSPF.

The IP address can be a valid IP address that is configured on the system, or it can be specified with asterisks (*) as wildcards. The valid wildcard specifications are shown in the following example. The result of coding a wildcard value is that all configured interfaces whose IP address matches the wildcard are configured as OSPF interfaces. Configured interface IP addresses and names are matched against possible wildcards in the order they appear in the following example with the name and any matching wildcard being the best match, x.y.z.* being second best, and so on.

```
interface name and any matching wildcard
x.y.z.*
x.y.*.*
x.*.*.*
*.*.*.* - Same as ALL
ALL - Same as *.*.*.*
```

Tip: For more information about how wildcard interfaces are parsed, see this [Method of assigning interface definitions to stack interfaces \(wildcard and explicit\)](#): in [z/OS Communications Server: IP Configuration Guide](#).

Because a stack could have a large number of Dynamic VIPAs (DVIPAs) defined, as well as DVIPA ranges, an additional wildcard capability exists on the OSPF_INTERFACE statement for use only with DVIPAs. Ranges of DVIPA interfaces can be defined using the subnet mask parameter on the OSPF_INTERFACE statement. This mode of definition applies to Dynamic VIPAs defined in the stack with VIPADEFINE, VIPABACKUP, or VIPARANGE. The range defined in this way are all the IP addresses that fall within the subnet defined by the mask and the IP address. When this type of wildcarding is being used, the value of the IP_ADDRESS parameter must be the subnet number of the range. Note that this subnet number is not equivalent to a DVIPA address as defined in VIPADEFINE or VIPABACKUP parameter of the VIPADYNAMIC statement in the TCP/IP profile. If VIPARANGE is defined, you should code DVIPA subnet address for the subnet number. For example, the following code defines a range of six addresses (9.67.101.9 to 9.67.101.14) that can be used for DVIPA addresses and matches any DVIPA interface that falls into the 9.67.101.8/29 subnet:

```
IP_ADDRESS = 9.67.101.8
SUBNET_MASK = 255.255.255.248
```

Alternatively, the following code does not because 9.67.101.17 is an address within the subnet range, not the subnet number itself (that would be 9.67.101.16). This second definition matches only an interface whose home address is 9.67.101.17.

```
IP_ADDRESS= 9.67.101.17
SUBNET_MASK=255.255.255.248
```

Name

The name of the interface. A valid value is any string 1 - 16 characters in length.

Rules:

- If this is not a wildcard interface definition, the name must match the link name that is coded for the corresponding IP address on the HOME statement or the interface name coded for the corresponding IPv4 INTERFACE statement in the TCP/IP profile.
- If this is a wildcard interface definition, then this parameter is used in conjunction with the defined wildcard IP address when searching for definitions to match a stack interface. For more details about this process, see [Method of assigning interface definitions to stack interfaces \(wildcard and explicit\)](#): in [z/OS Communications Server: IP Configuration Guide](#).

Subnet_Mask

The subnet mask of the subnet to which this interface attaches. This value must be the same for all routers attached to a common network. For more information, see [z/OS Communications Server: IP Configuration Guide](#). If you configure this interface in the TCP/IP profile using the IPv4 INTERFACE

statement and you configure a subnet mask on that statement that does not match the value that you specify on this parameter, OMROUTE issues message EZZ8164I and uses this subnet mask.

Destination_Addr

IP address of the host at the remote end of this interface. This parameter is valid only for point-to-point links. If this parameter is not specified for a point-to-point link, a route to the host at the remote end of the interface is not added to the appropriate TCP/IP route tables (main and policy-based tables) until OSPF communication is established with that host. A subnet route for the interface is added when OMROUTE is initialized whether or not this parameter is specified.

Attaches_To_Area

OSPF area to which this interface attaches. Valid values are 0.0.0.0 (the backbone), or any area defined by the AREA statement.

MTU

The maximum transmission unit size that OSPF adds to the appropriate routing tables (main and policy-based tables) for routes that use this interface. Valid values are in the range 0 - 65535. If you configure this interface in the TCP/IP profile using the IPv4 INTERFACE statement and you configure an MTU on that statement and the MTU that you configure on that statement does not match the MTU (the configured value or the default value) on this statement, OMROUTE issues message EZZ8163I and uses the MTU value on this statement.

Tip: See [z/OS Communications Server: IP Configuration Guide](#), in section Maximum transmission unit considerations, for additional information about how TCP/IP uses the MTU to determine the largest size frame to send.

Retransmission_Interval

Sets the frequency (in seconds) of retransmitting link-state update packets, link-state request packets, and database description packets. Valid values are in the range 1 - 65535 seconds.

If this parameter is set too low, needless retransmissions occur that could affect performance and interfere with neighbor adjacency establishment. It should be set to a higher value for a slower machine.

Transmission_Delay

This parameter is an estimate of the number of seconds that it takes to transmit link-state information over the interface. Each link-state advertisement has a finite lifetime of 1 hour. As each link-state advertisement is sent out from this interface, it is aged by this configured transmission delay. Valid values are in the range 1 - 65535 seconds.

Router_Priority

This value is used for broadcast and nonbroadcast multiaccess networks to elect the designated router, with the highest priority router being elected. Valid values are in the range 0 - 255.

A value of 0 indicates that OMROUTE never becomes the designated router. A value of 1 indicates the lowest possible eligible priority and a value of 255 indicates the highest possible priority.

Hello_Interval

This parameter defines the number of seconds between OSPF Hello packets being sent out on this interface. This value must be the same for all routers attached to a common network. Valid values are in the range 1 - 255 seconds.

DB_Exchange_Interval

The interval in seconds that the database exchange process cannot exceed. If the interval elapses, the procedure is restarted. This value must be larger than the Hello_Interval. If no value is specified, the DB_Exchange_Interval is set to the Dead_Router_Interval. Valid values are 2 through 65535.

Dead_Router_Interval

The interval in seconds, after not having received an OSPF Hello, that the neighbor is declared to be down. This value must be larger than the Hello_Interval. Setting this value too close to the Hello_Interval can result in the collapse of adjacencies. A value of 4*Hello_Interval is preferred. This value must be the same for all routers attached to a common network. Valid values are 2 - 65535.

Cost0

The OSPF cost for this interface. The cost is used to determine the shortest path to a destination. Valid values are in the range 1 - 65535.

Subnet

The meaning of this parameter depends on the interface type.

For an interface to a point-to-point link, this option enables the advertisement of a stub route to the subnet that represents the link rather than the host route for the other router's address. In effect, this parameter controls whether, for this interface, OMPROUTE implements option 1 (SUBNET=NO) or option 2 (SUBNET=YES) described in RFC 2328 (OSPF version 2) topic 12.4.1.1. For a detailed explanation of this option, see [the IPv4 interface information in z/OS Communications Server: IP Configuration Guide](#).

For a VIPA interface, this option suppresses advertisement of either the VIPA host or subnet route. Normally z/OS Communications Server advertises both a host route and a subnet route for owned VIPA interfaces. With this option set to NOVIPAHOST, the VIPA host route is suppressed and only the VIPA subnet route is advertised. With this option set to NOVIPASUBNET, the VIPA subnet route is suppressed and only the VIPA host route is advertised.

Legal values are:

- YES
- NO
- NOVIPASUBNET
- NOVIPAHOST

Guidelines:

- Using the NOVIPAHOST value has the same effect as setting SUBNET=YES or ADVERTISE_VIPA_ROUTES=SUBNET_ONLY, using the NOVIPASUBNET value is equivalent to setting ADVERTISE_VIPA_ROUTES=HOST_ONLY
- The ADVERTISE_VIPA_ROUTES option is the preferred method to suppress VIPA advertisements.

Rule: Do not use this option for dynamic VIPAs or for any VIPA whose subnet might exist on multiple hosts. If you do, problems can occur routing to all VIPAs that share the subnet.

Tips:

- Specifying SUBNET=YES on a VIPA interface has the same effect as specifying SUBNET=NOVIPAHOST.
- In order to fully suppress the VIPA subnet route, SUBNET=NOVIPASUBNET must be specified on every VIPA OSPF_INTERFACE statement that defines a VIPA in a common subnet.

Advertise_VIPA_Routes

This option is valid only on VIPA interfaces and controls how OMPROUTE advertises the VIPA address. The default value of HOST_AND_SUBNET advertises both the VIPA host and subnet route. With this option set to HOST_ONLY, only the VIPA host route is advertised. With this option set to SUBNET_ONLY, only the VIPA subnet route is advertised.

The value specified on the ADVERTISE_VIPA_ROUTES option overrides any value specified on the SUBNET option. Legal values are:

- HOST_AND_SUBNET
- HOST_ONLY
- SUBNET_ONLY

Rule: Do not specify SUBNET_ONLY for dynamic VIPAs or for any VIPA whose subnet might exist on multiple hosts. Problems can occur routing to all VIPAs that share the subnet when the subnet exists on multiple hosts.

Tip: The HOST_ONLY option must be specified for every VIPA in a common subnet. If the HOST_ONLY option is not specified for every VIPA in a common subnet, OMPROUTE still advertises the VIPA subnet route for the interfaces not specifying HOST_ONLY.

Authentication_Type

The security scheme to be used on the network to which the interface attaches. If parameter is not specified, takes on the default value specified for the area to which the interface is attached. Valid values for authentication types are MD5, which indicates MD5 cryptographic authentication as described in Appendix D of RFC 2328; PASSWORD, which indicates a simple password; or NONE, which indicates that no authentication is necessary to pass packets. All hosts on the network must be configured with the same security scheme.

Authentication_Key_ID

The identifier of the authentication key defined with the AUTHENTICATION_KEY keyword. This is a constant numeric value from 0 - 255, with a default value of 0. It is relevant only when MD5 cryptographic authentication is employed on the interface; otherwise, it is ignored. This field is provided for compatibility with other routers that might require identification of a key identifier with the authentication key.

Authentication_Key

The value of the authentication key for this interface. This value must be the same for all routers attached to a common medium. The coding of this parameter depends on the authentication type being used on this interface.

For authentication type *none*, this parameter is not required and is ignored if coded.

For authentication type *password*, code the password for OSPF routers that are attached to this subnet. Valid values are any characters from EBCDIC code page 1047 up to 8 characters in length coded within double quotation marks or any hexadecimal string up to 8 bytes (16 hexadecimal characters) long that begins with 0x.

For authentication type *MD5*, code the 16-byte MD5 authentication key for OSPF routers attached to this subnet. This value can be coded in one of the following ways:

- The standard method is with a 16-byte hexadecimal string beginning with 0x (0x plus 32 hexadecimal characters). In some cases, pwtokey can be used to generate hexadecimal MD5 keys. See [z/OS Communications Server: IP System Administrator's Commands](#) for more information.
- An additional method, which provides compatibility with Cisco, Extreme, and other vendor routers that use a Cisco-compatible CLI interface is to code the MD5 key as an ASCII string, specified in double quotation marks prefixed with A. For example, to be compatible with this Cisco key definition, use the following code:

```
ip ospf message-digest-key 4 md5 ABCDEFGHIJKLMNOP
```

This value would be coded in OMPROUTE as follows:

```
AUTHENTICATION_KEY_ID =4  
AUTHENTICATION_KEY = A"ABCDEFGHIJKLMNPO"
```

Demand_Circuit

This parameter, when coded with YES, causes Link State Advertisements (LSAs) to not be periodically refreshed over this interface. Only LSAs with real changes are advertised. In addition, coding this parameter to YES causes LSAs flooded over this interface to never age out. Valid values are YES or NO. For more information about the Demand_Circuit=YES and related topics, such as handling high cost links, see [z/OS Communications Server: IP Configuration Guide](#).

Hello_Suppression

This parameter is used only on point-to-point and point-to-multipoint interfaces that are demand circuits. It allows you to configure the interface for Hello Suppression. Valid values are ALLOW, REQUEST, or DISABLE.

If either or both sides specify DISABLE, Hello_Suppression is disabled. If both specify ALLOW, Hello_Suppression is disabled. If one specifies ALLOW and the other REQUEST, or if both specify REQUEST, Hello_Suppression is enabled.

PP_Poll_Interval

This parameter specifies the interval (in seconds) that OMPROUTE should use when attempting to contact a neighbor to reestablish a neighbor relationship when the relationship has failed, but the interface is still available. This parameter is meaningful only if Demand_Circuit is coded YES and Hello_Suppression has been enabled. Valid values are in the range 0 - 65535.

Parallel_OSPF

This parameter designates whether the OSPF interface is primary or backup when more than one OSPF interface is defined to the same subnet. Only one of these interfaces can be configured as primary, meaning that it is the interface to carry the OSPF protocol traffic between OMPROUTE and the subnet. Failure of the primary interface results in automatic switching of OSPF traffic to one of the backup interfaces. If the primary interface is later reactivated, OSPF traffic is not automatically switched back from the backup interface to the primary interface. If you want to switch OSPF traffic back to the primary interface, stop the backup interface. If none of the interfaces to the common subnet are configured as primary, a primary interface is selected by OMPROUTE. Valid values are BACKUP and PRIMARY.

Non_Broadcast

If the router is connected to a nonbroadcast, multiaccess network (NBMA), such as Frame Relay, coding a Non_Broadcast helps the router discover its neighbors. This can also be coded for a broadcast-capable network when you want OMPROUTE to unicast its packets instead of multicasting them. In addition to coding this parameter, each neighbor must be configured with the DR_NEIGHBOR parameter, for those neighbors that are eligible to become the designated router, or NO_DR_NEIGHBOR for those neighbors that are not eligible to become the designated router. This statement is ignored when this OSPF interface is coded as a wildcard. Valid values are YES or NO.

NB_Poll_Interval

This parameter specifies the frequency (in seconds) of hellos sent to neighbors that are inactive. You must set this poll interval consistently across all interfaces that attach to the same subnetwork for OSPF to function correctly. This statement is valid only when Non_Broadcast is coded as YES. Valid values are in the range 1 - 65535.

DR_Neighbor

Configures the IP interface address of a designated router-eligible neighbor adjacent to the router over this interface. In nonbroadcast multi-access networks, neighbors need to be configured to all OSPF routers on the network. Multiple DR_Neighbor statements can be coded on an OSPF_interface statement as necessary.

Guideline: You should not define neighbors on broadcast-capable or multicast-capable media. If you do define neighbors on these media, OMPROUTE can communicate OSPF information only with those neighbors that are defined (it does not form adjacencies with any additional neighbors).

No_DR_Neighbor

Configures the IP interface address of a nondesignated router-eligible neighbor adjacent to the router over this interface. In nonbroadcast multi-access networks, neighbors need to be configured to all OSPF routers on the network. Multiple No_DR_Neighbor statements can be coded on an OSPF_Interface statement as necessary.

Guideline: You should not define neighbors on broadcast-capable or multicast-capable media. If you do define neighbors on these media, OMPROUTE can communicate OSPF information only with those neighbors that are defined (it does not form adjacencies with any additional neighbors).

Retransmit Parameters

The following parameters are used by OMPROUTE to set values in the routes that use this interface; the values are added to the TCP/IP route tables. The values affect the TCP retransmit algorithms. When TCP packets are not acknowledged, TCP begins to retransmit these packets at certain time intervals. If these packets are not acknowledged after a certain number of retransmissions, TCP aborts the connection. The

time interval between retransmissions increases by approximately twice the previous interval until the packets are acknowledged or the connection times out.

The time intervals between retransmissions and the number of times packets are retransmitted before the connection times out differs for initial connection establishment and for data packets. For initial connection establishment, the initial time interval is set at approximately 3 seconds and the SYN packet is retransmitted 5 times before the connection is timed out. Data packets use a smoothed Round Trip Time (RTT) as the initial time interval and are retransmitted 15 times before the connection is timed out. All of the following parameters affect the data packet retransmission algorithm. Only the Min_Xmit_Time parameter affects the initial connection establishment.

Tip: A new route lookup is performed after every two retransmissions for a data packet. For more information about the route lookup process, see [Route selection algorithm in z/OS Communications Server: IP Configuration Guide](#). Be careful when you design networks with firewalls. A firewall in an alternate routing path can generate a RESET packet for the rerouted data packets, which causes TCP to abort the connection.

Max_Xmit_Time

Limits the TCP retransmission interval. Decreasing this value might decrease the total time it takes a connection to time out. Specifying Max_Xmit_Time assures that the interval time never exceeds the specified limit. The minimum value that can be specified for Max_Xmit_Time is 0. The maximum is 999.990. The default is 120 seconds. This parameter affects the initial connection establishment retransmission timeout for all APIs, except the Pascal API (TcpOpen), that are using the socket connect function.

Min_Xmit_Time

Sets a minimum retransmit interval. Increasing this value might increase the amount of time it takes for TCP to time out a connection. The minimum value that can be specified for Min_Xmit_Time is 0. The maximum is 99.990. The default is 0.5 (500 milliseconds).

RT_Gain

This value is the percentage of the latest Round Trip Time (RTT) to be applied to the smoothed RTT average. The higher this value, the more influence the latest packet's RTT has on the average. The minimum value that can be specified for RT_Gain is 0. The maximum value is 1.0. The default is 0.125. This parameter does not affect initial connection retransmission.

Variance_Gain

This value is the percentage of the latest RTT variance from the RTT average to be applied to the RTT variance average. The higher this value, the more influence the latest packet's RTT has on the variance average. The minimum value that can be specified for Variance_Gain is 0. The maximum value is 1.0. The default is 0.25. This parameter does not affect initial connection retransmission.

Variance_Mult

This value is multiplied against the RTT variance in calculating the retransmission interval. The higher this value, the more affect variation in RTT has on calculating the retransmission interval. The minimum value that can be specified for Variance_Mult is 0. The maximum value is 99.990. The default is 2. This parameter does not affect initial connection retransmission.

Delay_Acks

The delay acknowledgments value that is added to the routing tables for routes that use this interface. Specify YES to delay transmission of acknowledgments when a packet is received with the PUSH bit on in the TCP header. Specify NO to return acknowledgments immediately when a packet is received with the PUSH bit on in the TCP header. This parameter affects only connections that use the routes associated with this interface.

Even if you specify YES, you can override the delay acknowledgments behavior can be overridden by specifying the NODELAYACKS parameter on the TCP/IP stack PORT, PORTRANGE, or TCPCONFIG profile statements. The value NO can override the specification the DELAYACKS parameter on the TCP/IP stack PORT, PORTRANGE, and TCPCONFIG profile statements.

Valid values are YES and NO. The default value is YES.

Usage notes

When you configure multiaccess parallel interfaces (primary and secondary interfaces that have IP addresses in the same subnet) for OMPROUTE (OSPF), code the Parallel_OSPF=Primary parameter to set a specific interface as the primary interface. If none of the interfaces on the same subnet are coded as primary, OMPROUTE will select the primary interface from the set of interfaces attached to the subnet. In case of a primary interface failure, OMPROUTE uses the first available secondary interface and marks it as the primary interface.

RANGE statement

Use the RANGE statement to add ranges to OSPF areas. OSPF areas can be defined in terms of address ranges. External to the area, a single route is advertised for each address range. For example, if an OSPF area were to consist of all subnets of the class B network 128.185.0.0, it would be defined as consisting of a single address range. The address range would be specified as an address of 128.185.0.0 together with a mask of 255.255.0.0. Outside of the area, the entire subnetted network would be advertised as a single route to network 128.185.0.0.

Ranges can be defined to control which routes are advertised external to an area.

When OSPF is configured not to advertise the range, no interarea routes are advertised for routes that fall within the range. Ranges cannot be used for areas that serve as transit areas for virtual links. This does not prevent AS-external routes from being advertised if used in conjunction with the AS_BOUNDARY statement.

Syntax

➡ Range — IP_address — = — address — Subnet_Mask — = — mask ➡

Parameters

IP_Address

Common subnet portion of IP addresses in this range. Valid values are valid network and subnetwork addresses.

Subnet_Mask

Subnet mask with respect to the network range defined in IP_Address.

Area_Number

Area number for which to add this range. Valid values are any defined areas.

Advertise

Determines whether this range is advertised to other areas. Valid values are YES or NO.

RouterID statement

Use the RouterID statement as an alternative to specifying the RouterID parameter on the OSPF configuration statement. See [“OSPF statement”](#) on page 438 for the statement descriptions. The following concepts apply to the RouterID statement:

- If the RouterID statement is specified, the value configured is used as the OSPF router ID. This value must be one of the OSPF interface IP addresses that is configured for the stack.

Rule: Loopback and reserved 0.0.0.0 addresses are not valid OSPF interface IP addresses.

- If the router ID is not configured, one of the OSPF interface addresses will be used as the OSPF router ID, provided that the interface exists in the TCPIP profile and matches the corresponding OSPF interface statement in the OMPROUTE configuration file at startup.

Result: When OMPROUTE has to assign the router ID, it does not use dynamic VIPA IP addresses. This avoidance of dynamic VIPA IP addresses cannot be guaranteed; for example, if dynamic VIPAs are the only active OSPF interfaces when OMPROUTE chooses the router ID, then one of them will be chosen.

Guideline: Because dynamic VIPAs (DVIPAs) can move between z/OS hosts, the router ID should be a physical interface or a static VIPA, not a dynamic VIPA address. To ensure an appropriate router ID, specify the router ID to OMPROUTE.

Syntax

➤ RouterID — = — id ➤

Parameters

RouterID

A dotted-decimal value.

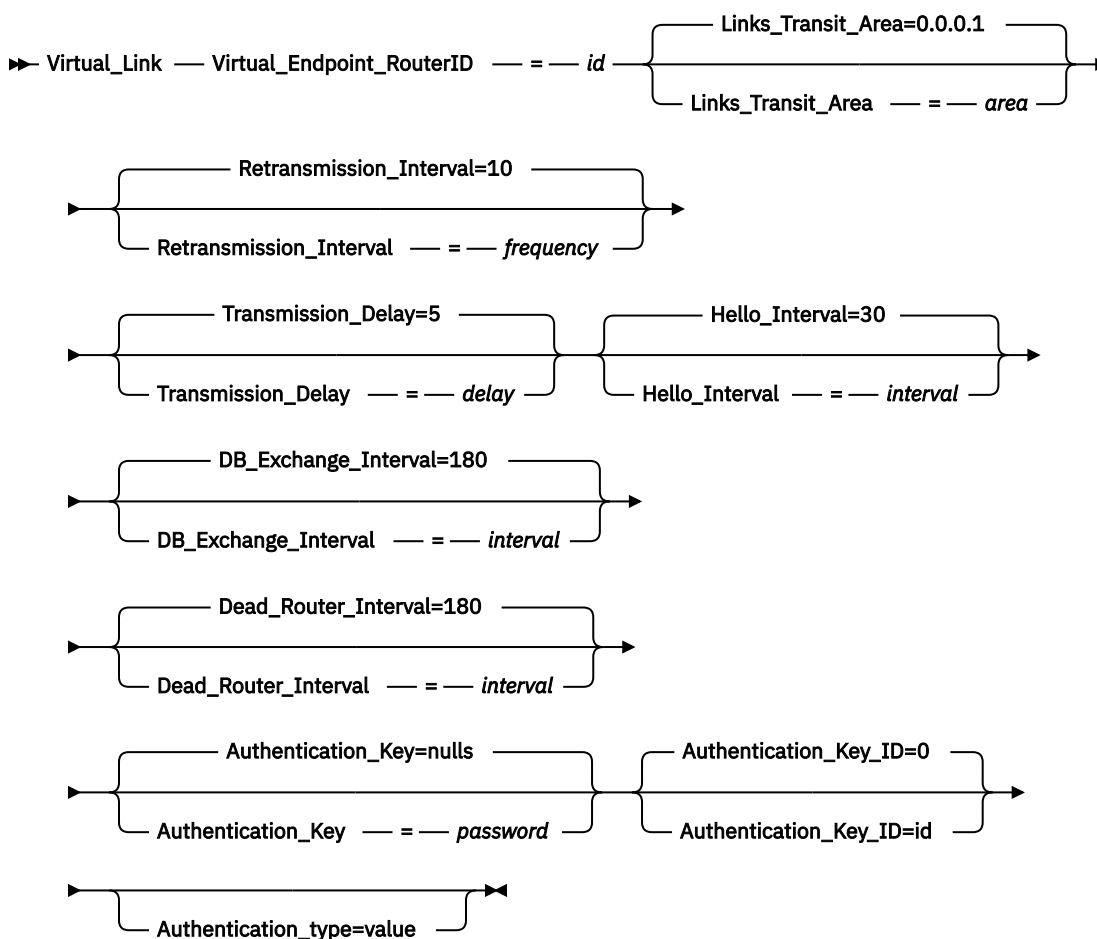

VIRTUAL_LINK statement

Use the VIRTUAL_LINK statement to configure a virtual link between two area border routers. To maintain backbone connectivity you must have all of your backbone routers interconnected either by permanent or virtual links. Virtual links are considered to be separate router interfaces connecting to the backbone area. Therefore, you are asked to specify many of the interface parameters when configuring a virtual link.

Virtual links can be configured between any two backbone routers that have an interface to a common nonbackbone, nonstub area. Virtual links are used to maintain backbone connectivity and must be configured at both endpoints.

Tip: OSPF virtual links are not to be confused with Virtual IP Address support (VIPA).

Syntax

Parameters

Virtual_Endpoint_RouterID

Router ID of the virtual neighbor (other endpoint). Router IDs are entered in the same form as IP addresses.

Links_Transit_Area

This is the nonbackbone, nonstub area through which the virtual link is configured. Virtual links can be configured between any two area border routers that have an interface to a common nonbackbone and nonstub area. Virtual links must be configured in each of the link's two endpoints. Valid values are any area defined by the AREA statement, except 0.0.0.0.

Retransmission_Interval

Sets the frequency (in seconds) of retransmitting link-state update packets, link-state request packets, and database description packets. Valid values are from 1 - 65 535 seconds.

Guideline: If this parameter is set too low, needless retransmissions occur that could affect performance and interfere with neighbor adjacency establishment. It should be set to a higher value for a slower machine.

Transmission_Delay

This parameter is an estimate of the number of seconds that it takes to transmit link-state information over the virtual link. Each link-state advertisement has a finite lifetime of 1 hour. As each link-state advertisement is sent out from this virtual link, it is aged by this configured transmission delay. Valid values are in the range 1 - 65 535 seconds.

Hello_Interval

This parameter defines the number of seconds between OSPF Hello packets being sent out from this virtual link. Valid values are in the range 1 - 255 seconds. The Hello_Interval should be set higher than the same value used on the intervening, actual OSPF interfaces.

DB_Exchange_Interval

The interval in seconds that the database exchange process cannot exceed. If the interval elapses, the procedure is restarted. This value must be larger than the Hello_Interval. If no value is specified, the DB_Exchange_Interval is set to the Dead_Router_Interval. Valid values are 2 - 65 535.

Dead_Router_Interval

The interval in seconds, after not having received an OSPF Hello, that the neighbor is declared to be down. This value must be larger than the Hello_Interval. Valid values are 2 - 65 535. The dead router interval should be set higher than the same value used on the intervening, actual, OSPF interfaces.

Authentication_Key

The value of the authentication key for this interface. This value must be the same for all routers attached to a common medium. The coding of this parameter depends on the authentication type being used on this interface.

For authentication type *none*, this parameter is not required and is ignored if coded.

For authentication type *password*, code the password for OSPF routers that are attached to this subnet. Valid values are any characters from EBCDIC code page 1047 up to 8 characters in length coded within double quotation marks or any hexadecimal string up to 8 bytes (16 hex characters) long that begins with 0x.

For authentication type *MD5*, code the 16-byte MD5 authentication key for OSPF routers attached to this subnet. This value can be coded in one of the following ways:

- The standard method is with a 16-byte hexadecimal string beginning with 0x (0x plus 32 hexadecimal characters). In some cases, pwtokey can be used to generate hexadecimal MD5 keys. See [z/OS Communications Server: IP System Administrator's Commands](#) for more information.
- An additional method, which provides compatibility with Cisco, Extreme, and other vendor routers that use a Cisco-compatible CLI interface is to code the MD5 key as an ASCII string, specified in double quotation marks prefixed with A. For example, to be compatible with this Cisco key definition, use the following code:

```
ip ospf message-digest-key 4 md5 ABCDEFGHIJKLMNOP
```

This value would be coded in OMPROUTE as follows:

```
AUTHENTICATION_KEY_ID =4  
AUTHENTICATION_KEY = A"ABCDEFGHIJKLMNPO"
```

Authentication_Key_ID

The identifier of the authentication key defined with the AUTHENTICATION_KEY keyword. This is a constant numeric value from 0 - 255, with a default value of 0. It is only relevant when MD5 cryptographic authentication is employed on the virtual link; otherwise, it is ignored. This field is provided for compatibility with other routers which might require identification of a key identifier with the authentication key.

Authentication_Type

The security scheme to be used over the virtual link. If not specified, the statement takes on the default value specified for the backbone area. Valid values for authentication types are MD5, which indicates MD5 cryptographic authentication as described in Appendix D of RFC 2328; PASSWORD, which indicates a simple password; or NONE, which indicates that no authentication is necessary to pass packets. Both hosts attached to the virtual link must be configured with the same security scheme.

RIP configuration statements

This topic contains descriptions of the following RIP configuration statements:

- ACCEPT_RIP_ROUTE
- FILTER
- IGNORE_RIP_NEIGHBOR
- ORIGINATE_RIP_DEFAULT
- RIP_INTERFACE
- SEND_ONLY

These statements are for configuring the RIP environment for IPv4. For information about the statements to be used for configuring IPv6 RIP, see [“IPv6 RIP configuration statements” on page 472.](#)

ACCEPT_RIP_ROUTE statement

Use the ACCEPT_RIP_ROUTE statement to allow a network, subnet, or host route to be accepted independent of whether the interface it was received on has the corresponding reception parameter enabled (network, subnet, or host). Routes added in this manner can be thought of as a list of exception conditions.

Restriction: Coding this statement does not enable updates for this destination to be received on RIP interfaces with RECEIVE_RIP=NO coded. Also, this does not override RIP version filters coded using the RECEIVE_RIP parameter on RIP_INTERFACE statements. For example, on a RIP_INTERFACE with RECEIVE_RIP=RIP2, a RIPV1 route that would otherwise be allowed by this statement is not received.

Syntax

➤ Accept_RIP_Route — IP_address — = — address ➤

Parameters

IP_address

Destination route to be unconditionally accepted.

FILTER statement

Use the FILTER statement can be coded stand-alone in the OMPROUTE configuration file (nosend and noreceive only) to apply to all configured RIP interfaces.

Syntax

➤ filter — = — (filter_type,dest_route,filter_mask) ➤

Parameters

filter_type

The *filter_type* can be any of the following values:

nosend

Specifies that routes matching the dest_route and filter_mask are not to be broadcast over RIP interfaces. This option serves as an RIP output filter.

noreceive

Specifies that routes matching the dest_route and filter_mask are to be ignored in broadcasts received over RIP interfaces. This option serves as a RIP input filter.

dest_route

The *dest_route* specifies the destination route in network, subnetwork, or host format in dotted decimal form. Alternatively, an asterisk (*), which matches *any* destination, can be coded to filter out all routes sent or received over an interface. The use of the asterisk is also referred to as a blackhole filter. This should be used in conjunction with either additional send or receive filters to allow only certain routes to be received, or advertised over an interface or set of interfaces.

Tip: When the Originate_RIP_Default statement is configured, the blackhole nosend filter does not prevent sending of the default route.

filter_mask

The *filter_mask* specifies the filter mask in dotted decimal form. If this value is not coded, the default filter mask is 255.255.255.255, meaning apply the filter to the *dest_route* as coded. Coding the filter mask has no meaning and is not valid if the *dest_route* is coded as an asterisk (*) for a *blackhole* filter.

IGNORE_RIP_NEIGHBOR statement

Use the IGNORE_RIP_NEIGHBOR statement to specify that RIP routing table broadcasts from the specified gateway are to be ignored. This option can be a RIP input filter.

Syntax

➤ Ignore_Rip_Neighbor — IP_address — = — address ➤

Parameters

IP_address

Specifies the IP address of the gateway from which routing table broadcasts are ignored. For multiple IP addresses, you must repeat the statement for each IP address.

ORIGINATE_RIP_DEFAULT statement

Use the ORIGINATE_RIP_DEFAULT statement to indicate under what conditions RIP supports Default route (destination/mask 0.0.0.0/0.0.0.0) generation.

This statement determines whether or not a default route is considered available by OMPROUTE RIP. The SEND_DEFAULT_ROUTES parameter on the RIP_INTERFACE statement determines whether or not an available default route is advertised by a particular RIP interface.

Syntax

Parameters

Condition

Condition for when RIP is to advertise this router as a default router. Valid values are:

Always

Always originate RIP default. This is the default value.

OSPF

Originate RIP default if OSPF routes are available.

Never

Never advertise this router as a default router.

Cost

Specifies the cost that RIP advertises with the default route that it originates. Valid values are in the range 1 - 16. The default value is 1.

Accept_Default

Specifies whether or not OMPROUTE RIP accepts default routes from inbound RIP packets whose cost is higher than default routes originated by the host.

Tip: OMPROUTE RIP always accept default routes from inbound RIP packets whose cost is lower than default routes originated by the host.

A value of **YES** indicates that OMPROUTE RIP replaces this router's originated default route with a default route learned from inbound RIP packets, even if that learned default route has a higher cost than this router's originated default route.

Results:

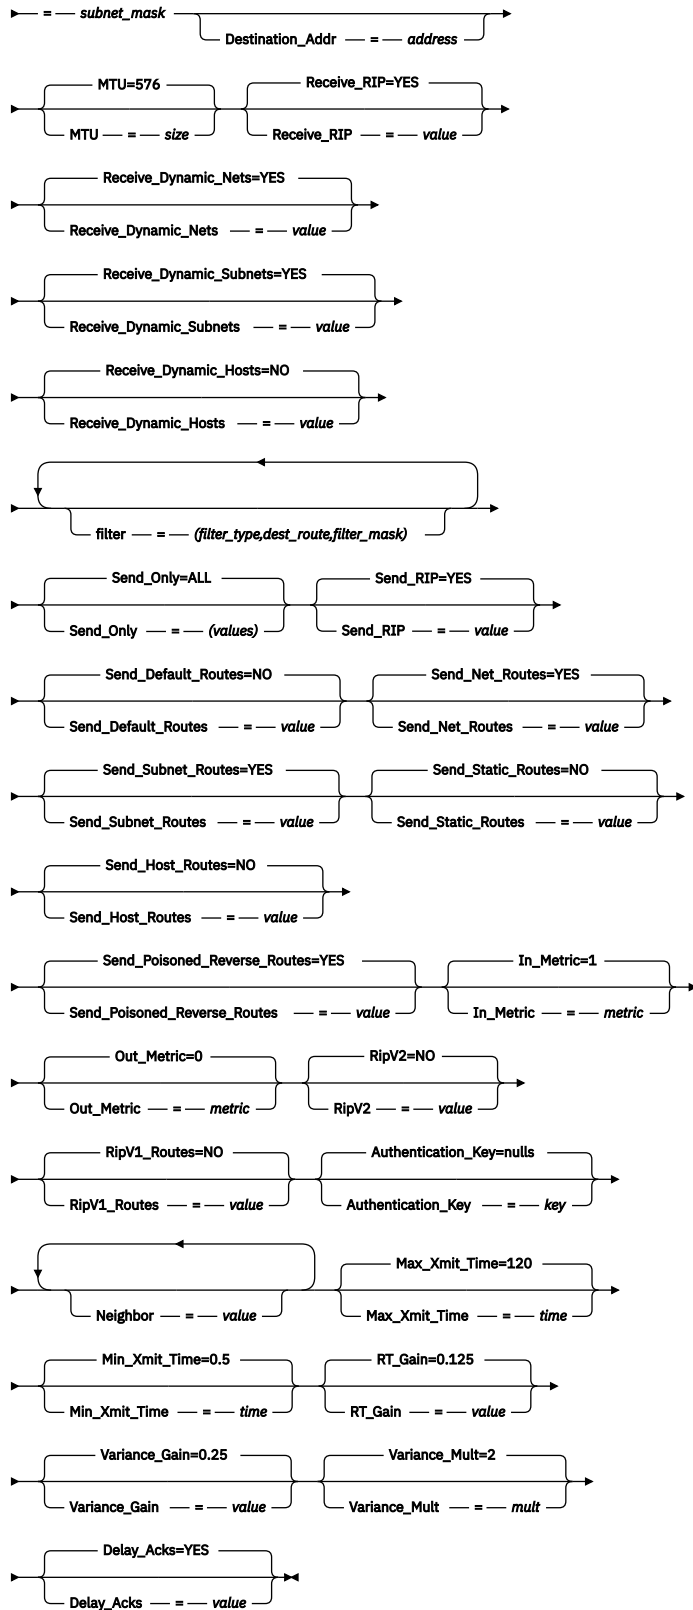

- When **YES** is coded, this router's originated default route is only used if no other default routes are learned from inbound RIP packets. A value of **NO** indicates that OMPROUTE RIP replaces this router's originated default route with a default route learned from inbound RIP packets only when the learned RIP route has a lower cost than this router's originated default route. This is the default value.
- When this parameter value is NO (either coded or by default), and the other parameters in this statement take their default values (CONDITION=ALWAYS and COST=1), OMPROUTE RIP never accepts default routes learned from RIP packets because it is not possible to learn a RIP route whose cost is less than 1.

RIP_INTERFACE statement

Use the RIP_INTERFACE statement to configure the RIP parameters for each IP interface. Replicated this statement in the configuration file for each IP interface over which RIP operates.

Syntax

➔ RIP_Interface — IP_address — — address — Name — — interface_name — Subnet_mask —➔

Parameters

IP_address

IP address of interface to be configured for RIP.

The IP address can be a valid IP address that is configured on the system or it can be specified with asterisks (*) as wildcards. The valid wildcard specifications are below. The result of coding a wildcard value are that all configured interfaces whose IP address matches the wildcard are configured as RIP interfaces. Configured interface IP addresses and names are matched against possible wildcards in the order they are in the following example with the name and any matching wildcard being the best match, x.y.z.* being second best, and so on.

```
interface name and any matching wildcard
x.y.z.*
x.y.*.*
x.*.*.*
*.*.*.* - Same as ALL
ALL - Same as *.*.*.*
```

Tip: For more information about how wildcard interfaces are parsed, see this [Method of assigning interface definitions to stack interfaces \(wildcard and explicit\)](#): in [z/OS Communications Server: IP Configuration Guide](#).

Because a stack could have a large number of Dynamic VIPAs (DVIPAs) defined, as well as DVIPA ranges, an additional wildcard capability exists on the RIP_INTERFACE statement for use only with DVIPAs. Ranges of DVIPA interfaces can be defined using the subnet mask parameter on the RIP_INTERFACE statement. This mode of definition applies to Dynamic VIPAs defined in the stack with VIPADEFINE, VIPABACKUP, or VIPARANGE. The range defined in this way is all the IP addresses that fall within the subnet defined by the mask and the IP address. When this type of wildcard search is being used, the value of the IP_ADDRESS parameter must be the subnet number of the range. For example, the following defines a range of 6 addresses (9.67.101.9 to 9.67.101.14) that can be used for DVIPA addresses and match any DVIPA interface that falls into the 9.67.101.8/29 subnet:

```
IP_ADDRESS = 9.67.101.8
SUBNET_MASK = 255.255.255.248
```

Alternatively, the following code does not because 9.67.101.17 is an address within the subnet range, not the subnet number itself (that would be 9.67.101.16). This second definition only matches an interface whose home address is 9.67.101.17.

```
IP_ADDRESS= 9.67.101.17
SUBNET_MASK=255.255.255.248
```

Name

The name of the interface. A valid value is any string 1 - 16 characters in length.

Rules:

- If this is not a wildcard interface definition, the name must match the link name that is coded for the corresponding IP address on the HOME statement or the interface name coded for the corresponding IPv4 INTERFACE statement in the TCP/IP profile.
- If this is a wildcard interface definition, then this parameter is used in conjunction with the defined wildcard IP address when searching for definitions to match a stack interface. For more details about this process, see [Method of assigning interface definitions to stack interfaces \(wildcard and explicit\)](#): in [z/OS Communications Server: IP Configuration Guide](#).

For Dynamic VIPA (DVIPA), link names are assigned programmatically by the stack when the DVIPA is created; therefore, the name field set on the RIP_INTERFACE statement is ignored by OMROUTE for DVIPAs.

Subnet_Mask

Subnet mask for the associated interface IP address. For more information, see [z/OS Communications Server: IP Configuration Guide](#). If you configure this interface in the TCP/IP profile using the IPv4 INTERFACE statement and you configure a subnet mask on that statement that does not match the

value that you specify on this parameter, OMPROUTE issues message EZZ8164I and uses this subnet mask.

Destination_Addr

IP address of the host at the remote-end of this interface. This parameter is valid only for point-to-point links; it is a required parameter for point-to-point links that cannot receive RIP2 packets (see the description of the RECEIVE_RIP parameter for more information about the level of RIP packets that an interface can receive). If this parameter is not specified for a point-to-point link that can receive RIP2 packets, a route to the host at the remote end of the interface is not added to the appropriate TCP/IP route tables (main and policy-based tables) until RIP communication is established with that host. A subnet route for the interface is added when OMPROUTE is initialized, whether or not this parameter is specified.

MTU

The maximum transmission unit size that RIP adds to the appropriate routing tables (main and policy-based tables) for routes that use this interface. Valid values are in the range 0 - 65535. If you configure this interface in the TCP/IP profile using the IPv4 INTERFACE statement and you configure an MTU on that statement and the MTU that you configure on that statement does not match the MTU (the configured value or the default value) on this statement, OMPROUTE issues message EZZ8163I and uses the MTU value on this statement.

Tip: See *z/OS Communications Server: IP Configuration Guide*, in section Maximum transmission unit considerations, for additional information about how TCP/IP uses the MTU to determine the largest size frame to send.

Receive_RIP

Specifies what type of RIP updates are accepted over this interface. Valid values are:

RIP1

Accept only RIP version 1 updates over this interface.

RIP2

Accept only RIP version 2 updates over this interface.

ANY

Accept RIP Version 1 and RIP Version 2 updates over this interface.

Rule: If RIP2 authentication is required and this value is coded, unauthenticated RIP1 packets are received over this interface. Also, if RIP2 authentication is not required, authenticated RIP2 packets are *not* be received over this interface, regardless of the value of RIPV2.

YES

If RIPV2=YES, then receive only RIP Version 2 updates over this interface. If RIPV2=No, then receive only RIP Version 1 updates over this interface. This is the default value.

NO

No RIP packets are received over this interface, regardless of any other filters.

Receive_Dynamic_Nets

Specifies whether or not to learn routes for networks over this interface. If this is not set, only nets explicitly allowed using the Accept_RIP_Route configuration statement is accepted on this interface. Valid values are YES or NO.

Receive_Dynamic_Subnets

Specifies whether or not to learn routes for subnets over this interface. If this is not set, only subnets explicitly allowed using the Accept_RIP_Route configuration statement is accepted on this interface. Valid values are YES or NO.

Receive_Dynamic_Hosts

Specifies whether or not to learn routes for hosts over this interface. If this is not set, only hosts explicitly allowed using the Accept_RIP_Route configuration statement is accepted on this interface. Valid values are YES or NO.

filter

Multiple filter parameters can be coded on a RIP_Interface statement. When specified on the RIP_Interface statement, the filter parameter applies only to the corresponding RIP interface. The

filter statement can also be coded stand-alone in the OMPROUTE configuration file (nosend and noreceive only) to apply to all configured RIP interfaces.

The *filter_type* can be any of the following values:

Value	Description
nosend	Specifies that routes matching the <i>dest_route</i> and <i>filter_mask</i> are not to be broadcast over this interface. This option serves as an RIP output filter.
noreceive	Specifies that routes matching the <i>dest_route</i> and <i>filter_mask</i> are to be ignored in broadcasts received over this interface. This option serves as an RIP input filter.
send	Specifies that routes matching the <i>dest_route</i> and <i>filter_mask</i> are to be broadcast over only this interface (or any other RIP interface with an equivalent filter). This option serves as an RIP output filter and can be used for inbound and outbound traffic splitting.
send_cond	Specifies that routes matching the <i>dest_route</i> and <i>filter_mask</i> are to be broadcast over only this interface when this interface is active (or any other active RIP interface with an equivalent filter). If this interface is inactive, the routes can be broadcast over other interfaces. This option serves as an RIP output filter and can be used for inbound and outbound traffic splitting.
receive	Specifies that routes matching the <i>dest_route</i> and <i>filter_mask</i> are to be received over only this interface (or any other RIP interface with an equivalent filter). If received over other RIP interfaces, the routes are discarded. This option serves as an RIP input filter.
receive_cond	Specifies that routes matching the <i>dest_route</i> and <i>filter_mask</i> are to be received over only this interface when this interface is active (or any other active RIP interface with an equivalent filter). If this interface is inactive, the routes can be received over all other active RIP interfaces. This option serves as an RIP input filter.

The *dest_route* specifies the destination route in network, subnetwork, or host format in dotted decimal form. Alternatively, an asterisk (*) can be coded in conjunction with the nosend and noreceive filter types. This serves as a *blackhole* filter that can be used to filter out all routes broadcast or received over an interface. This should be used in conjunction with either additional send or receive filters to allow only certain routes to be received, or advertised over an interface or set of interfaces.

Tip: If the blackhole nosend filter is used, it does not filter out the sending of the default route when the Originate_RIP_Default statement is also configured.

The *filter_mask* specifies the filter mask in dotted decimal form. If not coded, the default filter mask is 255.255.255.255, meaning apply the filter to the *dest route* as coded. Coding the filter mask has no meaning and is not valid if the *dest route* is coded as an asterisk (*) for a *blackhole* filter.

Send_Only

Specifies broadcast restrictions. Multiple values can be coded by separating the values with commas, unless ALL is coded. The valid values are:

ALL

Specifies no broadcast restrictions.

VIRTUAL

Broadcasts virtual IP addresses.

DEFAULT

Broadcasts the default route.

DIRECT

Broadcasts direct routes.

TRIGGERED

Only broadcasts routes when requested or when a route becomes inactive (metric 16).

VIRTUAL, DEFAULT, and DIRECT are Or'd together to determine what should be broadcast. Thus, coding SEND_ONLY=(VIRTUAL, DEFAULT) broadcasts virtual IP addresses and the default route.

Restriction: When ALL is coded it must not be enclosed within parentheses. When any of the other possible values are coded, they must be enclosed within parentheses.

When specified on the RIP_Interface statement, the Send_Only parameter applies only to the corresponding RIP interface. The Send_Only statement can also be coded stand-alone in the OMPROUTE configuration file to apply to all RIP interfaces.

Send_RIP

Specifies whether or not RIP advertisements are broadcast over this interface. Valid values are YES or NO.

Send_Default_Routes

Advertise the default route (destination 0.0.0.0), if it is available, in RIP responses sent from this IP source address. Valid values are YES or NO.

Restriction: If DEFAULT is coded on the Send_Only parameter or the stand-alone Send_Only statement, the Send_Default_Routes parameter is ignored and is set to YES.

Send_Net_Routes

Advertise all network level routes in RIP responses sent from this IP address. Valid values are YES or NO.

Send_Subnet_Routes

Advertise appropriate subnet-level routes in RIP responses sent from this IP address. Valid values are YES or NO.

In this context an appropriate subnet is one that meets RFC 1058 subnet advertisement constraints as follows:

- Natural Net must be the same as the IP source's natural net.
- Subnet mask must be the same.

Send_Static_Routes

Advertise static and direct routes in RIP responses sent from this IP source address. Split horizon is applied; that is, static routes configured over an interface are not included in RIP responses sent from that interface. Valid values are YES or NO.

Send_Host_Routes

Advertise host routes in RIP responses sent from this IP source address. In this context, a host route is one with a mask of 255.255.255.255. Valid values are YES or NO.

Send_Poisoned_Reverse_Routes

Advertise poisoned reverse routes over the interface corresponding to the next hop. A poison reverse route is one with an infinite metric (16). Valid values are YES or NO. If NO is specified, OMPROUTE still uses split horizon.

In_Metric

Specifies the value of the metric to be added to RIP routes that are received over this interface before the routes are installed in the appropriate routing tables (main and policy-based tables). Valid values are in the range 1 - 15.

Out_Metric

Specifies the value of the metric to be added to RIP routes advertised over this interface. Valid values are in the range 0 - 15.

RipV2

Enables RIP V2 packets to be sent on this link. Valid values are YES or NO. If YES, all RIP packets sent on this link are RIPV2. If NO, all RIP packets sent on this link are RIPV1. See the RECEIVE_RIP description in this list for information about configuring the level of RIP packets that can be received on this link.

RipV1_Routes

Specifies whether RIP V1 routes should be advertised on this RIP V2 link. Valid values are YES or NO.

Authentication_Key

RIP V2 authentication key. Only used for RIP V2 packets. Coding this key does not prevent reception of unauthenticated RIP V1 packets. To ensure that only authenticated RIP packets can be received over this interface, code RECEIVE_RIP=RIP2 in addition to this parameter. Valid values are any alphanumeric string from code page 1047 up to 16 characters in length coded within double quotation marks, or any hexadecimal string which begins with 0x.

Rules:

- If the value is entered in characters (rather than the hexadecimal string), that value is case sensitive.
- If an authentication key is not provided, authenticated RIP V2 packets are not received, even if RECEIVE_RIP=ANY.

Neighbor

Specifies the IP address of a single neighboring router. Multiple Neighbor parameters can be coded on a RIP_Interface statement to specify each adjacent RIP router. Use the Neighbor parameter when the interface is not point-to-point, does not support broadcast, and either does not support multicast or is using RIP version 1. For example, if you are using RIP version 1, use the Neighbor parameter for OSA interfaces that do not have the IPBCAST parameter specified on the LINK or INTERFACE statement in the TCPIP PROFILE.

Guideline: Do not define neighbors on multicast-capable media if this interface supports RIP V2, or broadcast-capable media for interfaces that support RIP V1 or RIP V2. If you define neighbors on these media, OMPROUTE is able to communicate RIP information *only* with those neighbors that are defined (it does not learn about any additional neighbors).

Retransmit Parameters

The following parameters are used by OMPROUTE to set values in the routes that use this interface; the values are added to the TCP/IP route tables. The values affect the TCP retransmit algorithms. When TCP packets are not acknowledged, TCP begins to retransmit these packets at certain time intervals. If these packets are not acknowledged after a certain number of retransmits, TCP aborts the connection. The time interval between retransmissions increases by approximately twice the previous interval until the packets are acknowledged or the connection times out.

The time intervals between retransmissions and the number of times packets are retransmitted before the connection times out differs for initial connection establishment and for data packets. For initial connection establishment, the initial time interval is set at approximately 3 seconds, and the SYN packet is retransmitted 5 times before the connection is timed out. Data packets use a smoothed Round Trip Time (RTT) as the initial time interval and are retransmitted 15 times before the connection is timed out. All of the following parameters affect the data packet retransmission algorithm. Only the Min_Xmit_Time parameter affects the initial connection establishment.

Tip: A new route lookup is performed after every two retransmissions for a data packet. For more information about the route lookup process, see [Route selection algorithm in z/OS Communications Server: IP Configuration Guide](#). Be careful when you design networks with firewalls. A firewall in an alternate routing path can generate a RESET packet for the rerouted data packets, which causes TCP to abort the connection.

Max_Xmit_Time

Limits the TCP retransmission interval. Decreasing this value might decrease the total time it takes a connection to time out. Specifying Max_Xmit_Time assures that the interval time never exceeds the specified limit. The minimum value that can be specified for Max_Xmit_Time is 0. The maximum is 999.990. The default is 120 seconds. This parameter affects the initial connection establishment retransmission timeout for all APIs, except the Pascal API (TcpOpen), that are using the socket connect function.

Min_Xmit_Time

Sets a minimum retransmit interval. Increasing this value might increase the amount of time it takes for TCP to time out a connection. The minimum value that can be specified for Min_Xmit_Time is 0. The maximum is 99.990. The default is 0.5 (500 milliseconds).

RT_Gain

This value is the percentage of the latest Round Trip Time (RTT) to be applied to the smoothed RTT average. The higher this value, the more influence the latest packet's RTT has on the average. The minimum value that can be specified for RT_Gain is 0. The maximum value is 1.0. The default is 0.125. This parameter does not affect initial connection retransmission.

Variance_Gain

This value is the percentage of the latest RTT variance from the RTT average to be applied to the RTT variance average. The higher this value, the more influence the latest packet's RTT has on the variance average. The minimum value that can be specified for Variance_Gain is 0. The maximum value is 1.0. The default is 0.25. This parameter does not affect initial connection retransmission.

Variance_Mult

This value is multiplied against the RTT variance in calculating the retransmission interval. The higher this value, the more affect variation in RTT has on calculating the retransmission interval. The minimum value that can be specified for Variance_Mult is 0. The maximum value is 999.990. The default is 2. This parameter does not affect initial connection retransmission.

Delay_Acks

The delay acknowledgments value that is added to the routing tables for routes that use this interface. Specify YES to delay transmission of acknowledgments when a packet is received with the PUSH bit on in the TCP header. Specify NO to return acknowledgments immediately when a packet is received with the PUSH bit on in the TCP header. This parameter affects only connections that use the routes associated with this interface.

Even if you specify YES, you can override the delay acknowledgments behavior by specifying the NODELAYACKS parameter on the TCP/IP stack PORT, PORTRANGE, or TCPCONFIG profile statements. A value of NO can override the specification of the DELAYACKS parameter on the TCP/IP stack PORT, PORTRANGE, and TCPCONFIG profile statements.

Valid values are YES and NO. The default value is YES.

SEND_ONLY statement

The SEND_ONLY statement can be coded stand-alone in the OMPROUTE configuration file to apply to all RIP interfaces.

Syntax**Parameters****(values)**

Specifies broadcast restrictions. Multiple values can be coded by separating the values with commas, unless ALL is coded. The valid values are:

ALL

Specifies no broadcast restrictions.

VIRTUAL

Broadcasts virtual IP addresses.

DEFAULT

Broadcasts the default route.

DIRECT

Broadcasts direct routes.

TRIGGERED

Only broadcast routes when requested or when a route becomes inactive (metric 16).

VIRTUAL, DEFAULT, and DIRECT are OR'd together to determine what should be broadcast. Thus, coding SEND_ONLY=(VIRTUAL, DEFAULT) broadcasts virtual IP addresses and the default route. When ALL is coded, it must not be enclosed within parentheses. When any of the other possible values are coded, they must be enclosed within parentheses.

When specified on the SEND_ONLY statement in the OMPROUTE configuration file, it applies to all RIP_Interfaces. The SEND_ONLY parameter can also be coded on the RIP_INTERFACE statement. When specified on the RIP_INTERFACE statement, the SEND_ONLY parameter applies only to the corresponding RIP_Interface.

IPv6 OSPF configuration statements

This topic contains descriptions of the following IPv6 OSPF configuration statements:

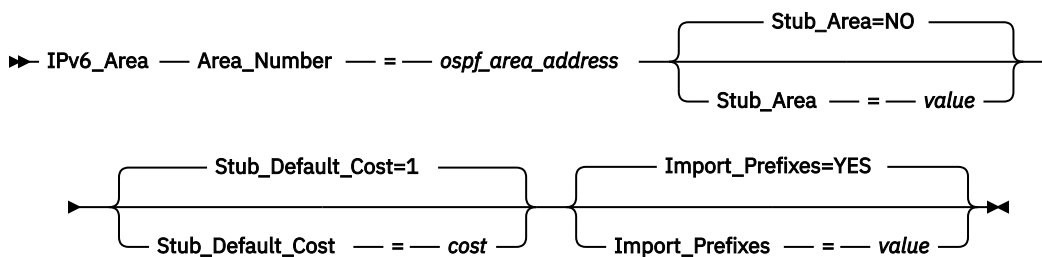

- IPv6_AREA
- IPv6_AS_BOUNDARY_ROUTING
- IPv6_OSPF
- IPv6_OSPF_INTERFACE
- IPv6_RANGE
- IPv6_VIRTUAL_LINK

See [z/OS Communications Server: IP System Administrator's Commands](#) for information about how to display configuration information.

IPv6_AREA statement

Use the IPv6_AREA statement to set the parameters for an IPv6 OSPF area. If no areas are defined, OMPROUTE assumes that all the router's directly attached networks belong to the backbone area (area ID 0.0.0.0).

Syntax

Parameters

Area_Number

The 32-bit OSPF area number in dotted decimal.

Stub_Area

Specifies whether this area is a stub area or not. Valid values are YES or NO.

Restrictions: If you specify Stub_area = YES, the area does not receive any AS external link advertisements, reducing the size of your database and decreasing memory usage for routers in the stub area. The following restrictions apply:

- You cannot configure virtual links through a stub area.
- You cannot configure a router within the stub area as an AS boundary router.
- You cannot configure the backbone as a stub area.

External routing in stub areas is based on a default route. Each area border router attaching to a stub area originates a default route for this purpose. The cost of this default route is also configurable with the IPv6_AREA statement.

Stub_Default_Cost

The cost that an OMPROUTE area border router associates with the default route that it generates into the stub area. Valid values are in the range 1 - 16 777 215.

Import_Prefixes

If this area is a stub area, indicates whether prefixes from neighboring areas are imported. Valid values are YES or NO.

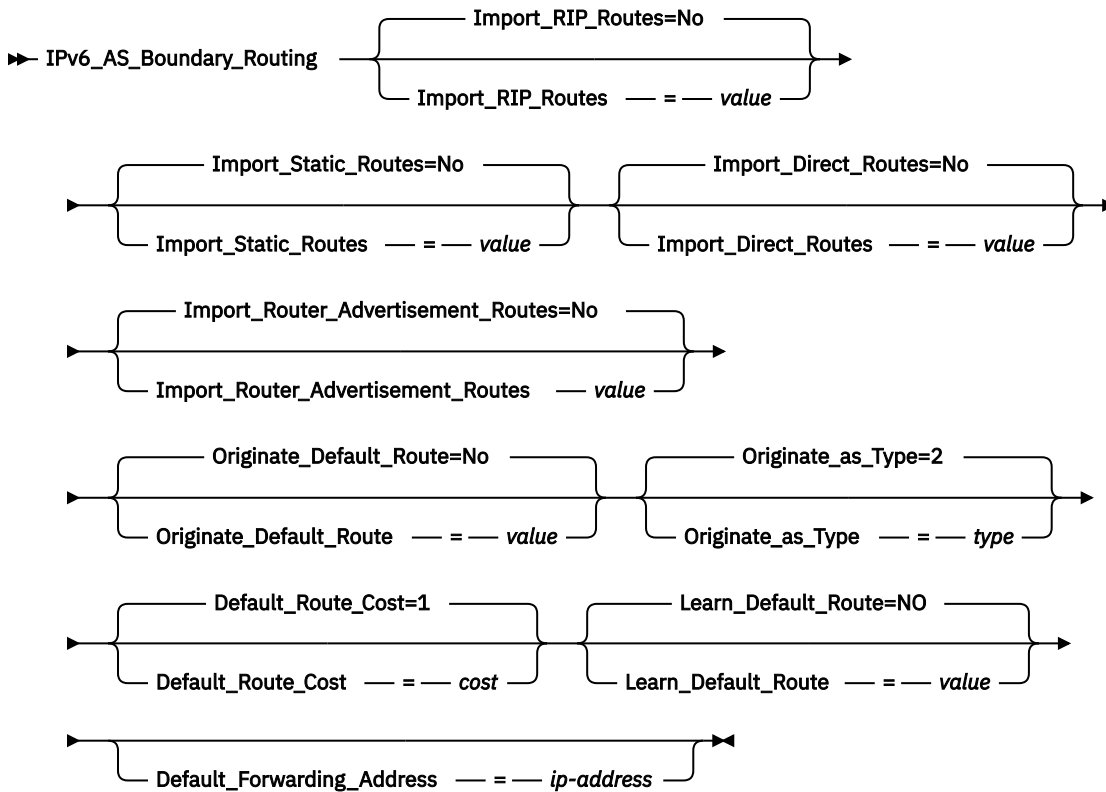

Tip: A stub area with Import_Prefixes set to NO is commonly referred to in RFCs and other standards documentation as a Totally Stubby Area.

IPv6_AS_BOUNDARY_ROUTING statement

Use the IPv6_AS_BOUNDARY_ROUTING statement to enable the AS boundary routing capability, which allows you to import routes learned from other methods (IPv6 RIP, statically configured, or direct routes) into the IPv6 OSPF domain. All routes are imported as either Type 1 or Type 2 external routes, depending on what was coded on the Comparison statement. The metric type used when importing routes determines how the imported cost is viewed by the IPv6 OSPF domain. When comparing Type 2 metrics, only the external cost is considered in selecting the best route. When comparing Type 1 metrics, the external and internal costs of the route are combined before making the comparison.

Requirement: This statement must be coded even if the only route you want to import is the default route (prefix length 0).

Syntax

Parameters

Import_RIP_Routes

Specifies whether routes learned by IPv6 RIP are imported into the IPv6 OSPF routing domain. Valid values are YES or NO.

Import_Static_Routes

Specifies whether static routes (routes defined to the TCP/IP stack using the BEGINROUTES statement) are imported into the IPv6 OSPF routing domain. Valid values are YES or NO.

Import_Direct_Routes

Specifies whether IPv6 direct routes are imported into the IPv6 OSPF routing domain. Valid values are YES or NO.

Import_Router_Advertisement_Routes

Specifies whether routes learned by the TCP/IP stack from IPv6 Router Advertisements are imported into the IPv6 OSPF routing domain. Valid values are YES and NO.

Tip: If a router is advertising a route into the OSPF domain on a link LSA, it is considered an OSPF internal route, regardless of whether or not it is also being advertised in an IPv6 Router Advertisement. Therefore, this parameter only controls routes that are only advertised by routers in IPv6 Router Advertisements.

Originate_Default_Route

Specifies whether or not this host originates an AS External default route into the IPv6 OSPF domain. If YES and Default_Forwarding_Address is not also coded (or is coded to ::), this host advertises itself as a default router. Valid values are YES or NO.

Originate_as_Type

Specifies the external type assigned to the default route originated by this host if Originate_Default_Route is YES. Valid values are 1 or 2.

Tip: See the comparison parameter in [“IPv6_OSPF statement” on page 464](#) for more information about external route types.

Default_Route_Cost

Specifies the cost that IPv6 OSPF associates with the default route originated by this host if Originate_Default_Route is YES. Valid values are in the range 0 - 16 777 215.

Learn_Default_Route

Specifies whether IPv6 OSPF learns default routes from inbound packets when their cost is equal to or higher than the cost of the default route originated by this host. Valid values are YES or NO. If this parameter is set to NO, then only default routes with lower cost than the one originated by this host are learned.

Default_Forwarding_Address

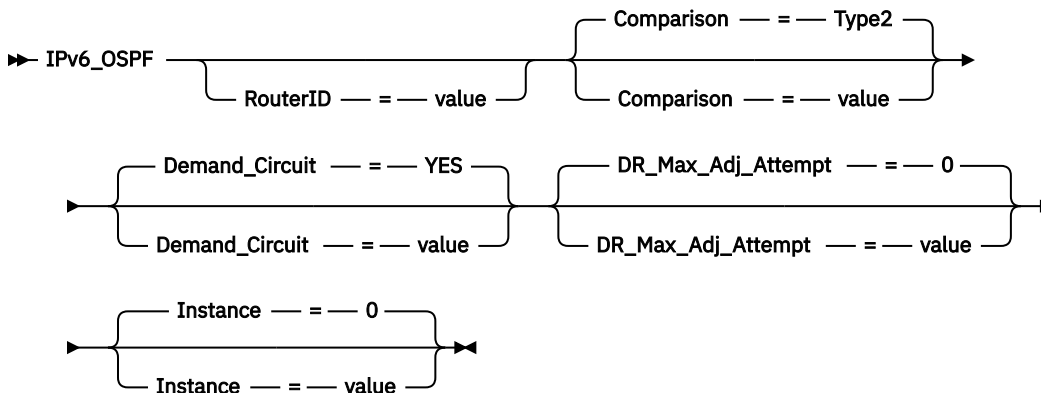

If Originate_Default_Route is YES, this optional parameter can be used to specify that this host should originate a default route on behalf of a different router. This parameter is not needed if this host is to advertise itself as the default router. It should only be used when the default router is another router that this host can route to, which is not capable of advertising an IPv6 OSPF default route on its own behalf. In that case, this parameter should be set to a reachable IP address on the other router.

Restriction: This address must be reachable using an OSPF intra-area or inter-area route (labelled as SPF or SPIA in the RT6TABLE display, or labelled as DIR but using an OSPF interface). This route could be a host, prefix, or default route. If no eligible route is found, the forwarding address is not included in the advertisements generated by this statement.

IPv6_OSPF statement

Use the IPv6_OSPF statement to specify various parameters that apply globally to IPv6 OSPF, either to all interfaces or to the overall IPv6 OSPF autonomous system.

Syntax

Parameters

RouterID

Every router in an IPv6 OSPF routing domain must be assigned a unique 32-bit router ID.

The value used for the IPv6 OSPF router ID is chosen as follows:

- If this router ID is configured, the value configured is used as the IPv6 OSPF router ID.

Rule: The reserved 0.0.0.0 address cannot be used as a router ID.

- If this router ID is not configured and IPv4 OSPF is also active on OMPROUTE, then the IPv4 Router ID value is also be used for IPv6.

Valid values are any 32-bit value, in dotted decimal format (in other words, specified as an IPv4-style IP address).

Restriction: If IPv4 OSPF is NOT active, then RouterID is a required configuration parameter.

Comparison

Tells OMPROUTE where external routes fit in the IPv6 OSPF hierarchy. IPv6 OSPF supports two types of external metrics. Type1 external metrics are equivalent to the link state metric. Type2 external metrics are greater than the cost of any path internal to the AS. Use of Type2 external metrics assumes that routing between autonomous systems is the major cost of routing a packet, and eliminates the need for conversion of external costs to internal link state metrics. Valid values are Type1 (or 1) or Type2 (or 2).

For more information about the COMPARISON configuration parameter, see [z/OS Communications Server: IP Configuration Guide](#).

Demand_Circuit

Global demand circuit setting. Coding YES enables demand circuits for IPv6 OSPF. Demand circuit parameters can then be coded on the IPv6_OSPF_Interface statement. Valid values are Yes or No.

DR_Max_Adj_Attempt

Specifies the maximum number of adjacency attempts to be used for reporting and controlling futile neighbor state loops. After the adjacency attempt count for a neighboring designated router reaches the threshold, an informational message is issued to report the problem. If a redundant interface is available that can reach the neighbor, adjacency formation is attempted over that interface. An informational message is issued to report the interface switch and the adjacency formation attempt. Valid values are in the range 0 - 100. The value 0 indicates infinite retries.

For information about futile neighbor state loops, see the [Minimizing the routing responsibility of z/OS Communications Server](#) in [z/OS Communications Server: IP Configuration Guide](#). For the types of interfaces supporting the futile neighbor state loop detection for OSPF, see [“Interfaces supported by OMPROUTE”](#) on page 489.

Instance

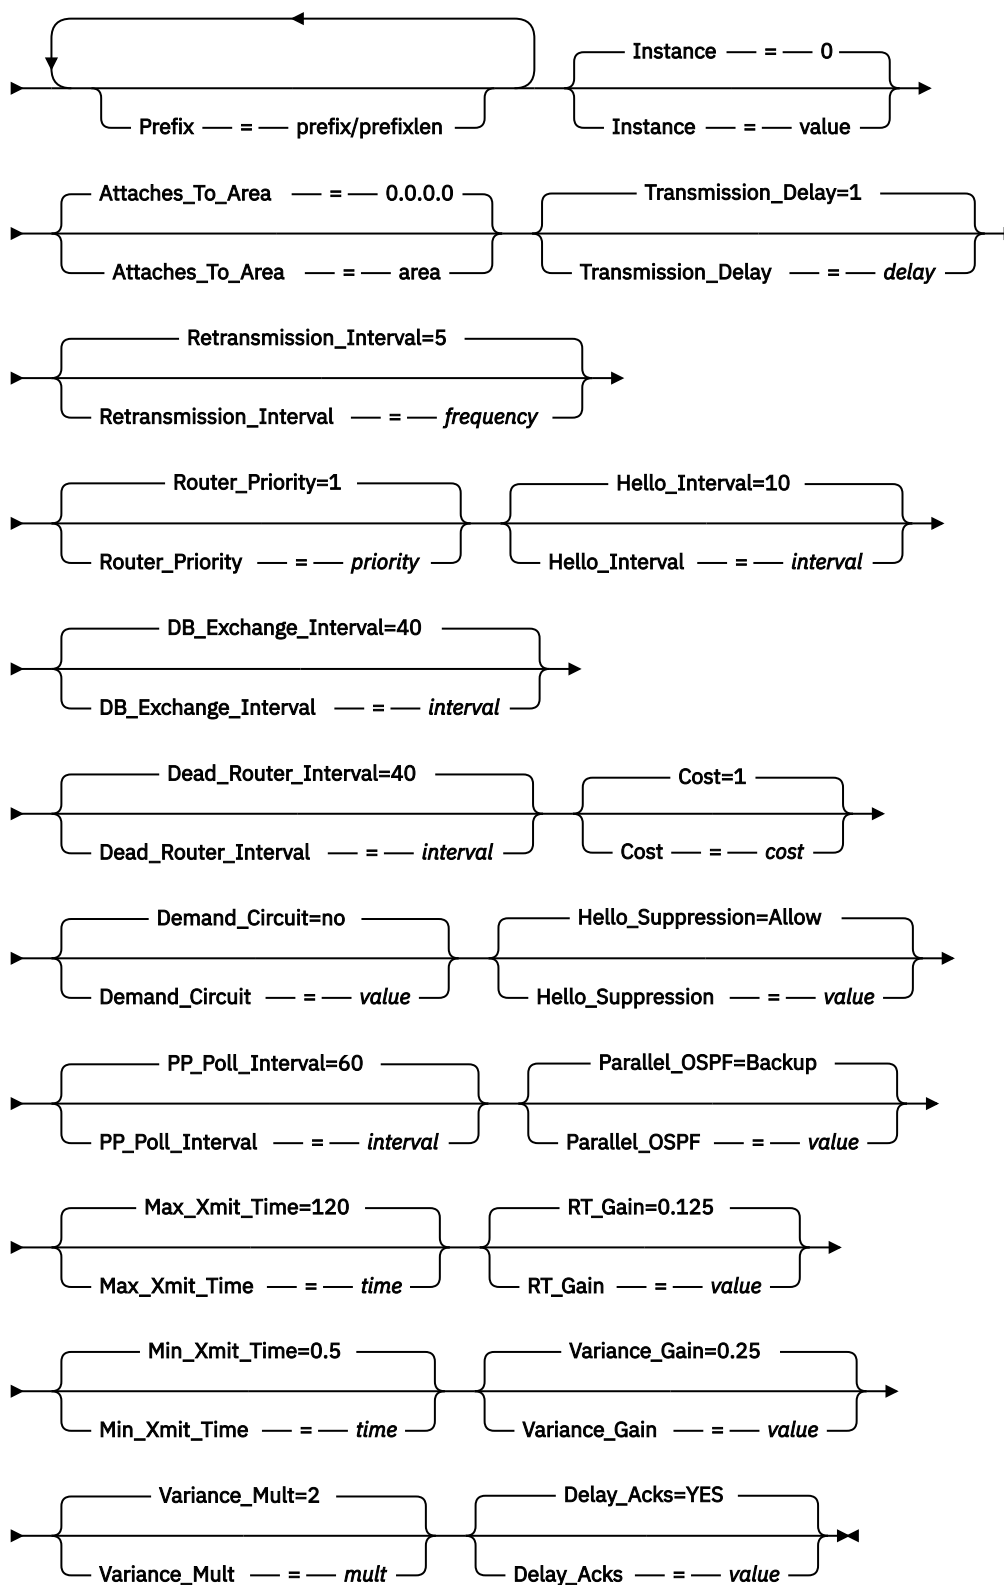

Provides the default instance number for OMPROUTE. OMPROUTE supports only one instance of IPv6 OSPF on a link, and this parameter specifies the default value for all IPv6 OSPF interfaces. This value can be overridden on individual IPv6_OSPF_Interface statements. Valid values are any integer from 0 - 255.

IPv6_OSPF_INTERFACE statement

Use the IPv6_OSPF_INTERFACE statement to set the IPv6 OSPF parameters for the TCP/IP network interfaces. Replicate this statement in the configuration file for each IPv6 interface over which OSPF operates.

Syntax

➤ IPv6_OSPF_Interface — Name — = — *interface_name* ➔

Parameters

Name

The name of the interface.

This name must match the interface name coded on the INTERFACE or VIPADYNAMIC statement in the TCP/IP profile. Valid values are any character string of 1 - 16 characters in length. Wildcard names (terminating in *) can be coded. For example, OSAQDIO* would match stack interfaces named OSAQDIO1, OSAQDIO2, OSAQDIOABC, and so forth.

Tips:

- For more information about how wildcard interfaces are parsed, see the [step about defining IPv6 interfaces in z/OS Communications Server: IP Configuration Guide](#).
- For the names to use when defining IPv6 dynamic XCF interfaces, see the [step about defining IPv6 interfaces in z/OS Communications Server: IP Configuration Guide](#).

Prefix

Specifies a prefix that is on the link to which the interface attaches. For each configured Prefix parameter, OMPROUTE adds a direct route to the prefix identified by the first *prefixlen* bits of *prefix*. Valid values for *prefix* are any colon-hexadecimal IPv6 address. Valid values for *prefixlen* are any integer value from 1 - 127. The prefix identified by the first *prefixlen* bits of *prefix* must not be a multicast prefix, a link-local prefix, or all zeros.

Guideline: If routers on the link are advertising prefixes using either IPv6 OSPF or IPv6 Router Discovery, prefixes being advertised as on-link by the routers should not be configured using this keyword. However, if IPv6 Router Discovery or IPv6 OSPF is not in use by the routers on the link or there is a need to supplement the list of prefixes being advertised as on-link by the routers, this keyword can be used. If the prefix is configured using this keyword and is also advertised by a router as being on-link, the route in the TCPIP stack's route table is the route added by OMPROUTE as a result of this keyword being specified. Any route for the same prefix that is learned from IPv6 OSPF or Router Discovery is ignored as long as the OMPROUTE-configured route exists.

Instance

Specifies the IPv6 protocol instance number for this interface. This value should be the same as the instance value of other IPv6 OSPF hosts or routers that OMPROUTE communicates with on this link. This value is set on all outgoing IPv6 OSPF packets, and all incoming IPv6 OSPF packets whose instance value does not match the value coded for this interface are ignored. This permits multiple instances of OSPF to be run on this link. OMPROUTE supports only one instance per link; however, by coding this parameter, OMPROUTE can interact with other routers that can support multiple instances. This value defaults to the value coded on the Instance parameter of the IPv6_OSPF configuration statement. If that value is not coded, the default is 0. Valid values are in the range 1 - 255.

Attaches_To_Area

IPv6 OSPF area to which this interface attaches. Valid values are 0.0.0.0 (the backbone), or any area defined by the IPv6_AREA statement.

Retransmission_Interval

Sets the frequency (in seconds) of retransmitting link-state update packets, link-state request packets, and database description packets. Valid values are in the range 1 - 65535 seconds.

Guideline: If this parameter is set too low, needless retransmissions occur that could affect performance and interfere with neighbor adjacency establishment. It should be set to a higher value for a slower machine.

Transmission_Delay

This parameter is an estimate of the number of seconds that it takes to transmit link-state information over the interface. Each link-state advertisement has a finite lifetime of 1 hour. As each link-state advertisement is sent out from this interface, it is aged by this configured transmission delay. Valid values are in the range 1 - 65535 seconds.

Router_Priority

This value is used for multiaccess networks to elect the designated router, with the highest priority router being elected. Valid values are in the range 0 - 255. A value of 0 indicates that OMROUTE cannot become designated router.

A value of 1 indicates the lowest possible eligible priority and a value of 255 indicates the highest possible priority. A value of 0 indicates that OMROUTE is not eligible to be a designated router on this link.

Hello_Interval

This parameter defines the number of seconds between IPv6 OSPF Hello packets being sent out this interface. This value must be the same for all routers attached to a common link. Valid values are in the range 1 - 255 seconds.

DB_Exchange_Interval

The interval in seconds that the database exchange process cannot exceed. If the interval elapses, the procedure is restarted. This value must be larger than the Hello_Interval. If no value is specified, the DB_Exchange_Interval is set to the Dead_Router_Interval. Valid values are 2 through 65535.

Dead_Router_Interval

The interval in seconds, after not having received an IPv6 OSPF Hello, that the neighbor is declared to be down. This value must be larger than the Hello_Interval. Setting this value too close to the Hello_Interval can result in the collapse of adjacencies. A value of 4*Hello_Interval is preferred. This value must be the same for all routers attached to a common link. Valid values are 2 to 65535.

Cost

The OSPF cost for this interface. The cost is used to determine the shortest path to a destination. Valid values are in the range 1 - 65535.

Demand_Circuit

This parameter, when coded with YES, causes Link State Advertisements (LSAs) to not be periodically refreshed over this interface. Only LSAs with real changes are advertised. In addition, coding this parameter to YES causes LSAs flooded over this interface to never age out. Valid values are YES or NO. For more information about the Demand_Circuit=YES and related topics, such as handling high cost links, see [z/OS Communications Server: IP Configuration Guide](#).

Hello_Suppression

This parameter is meaningful only for demand circuits. This parameter allows you to configure the interface to request Hello_Suppression. This parameter is used only on point-to-point and point-to-multipoint interfaces. Valid values are ALLOW, REQUEST, or DISABLE.

If either or both sides specify DISABLE, Hello_Suppression is disabled. If both specify ALLOW, Hello_Suppression is disabled. If one specifies ALLOW and the other REQUEST, or if both specify REQUEST, Hello_Suppression is enabled.

PP_Poll_Interval

This parameter specifies the interval (in seconds) that OMROUTE should use when attempting to contact a neighbor to reestablish a neighbor relationship when the relationship has failed, but the interface is still available. This parameter is meaningful only if Demand_Circuit is coded YES and Hello_Suppression has been enabled. Valid values are in the range 0 - 65535.

Parallel_OSPF

This parameter designates whether the IPv6 OSPF interface is primary or backup when more than one IPv6 OSPF interface is defined to the same link. Only one of these interfaces can be configured as primary, meaning that it is the interface to carry the IPv6 OSPF protocol traffic between OMROUTE and the subnet. Failure of the primary interface results in automatic switching of OSPF traffic to one of the backup interfaces. If the primary interface is later reactivated, IPv6 OSPF traffic is not automatically switched back from the backup interface to the primary interface. If you want to switch OSPF traffic back to the primary interface, the backup interface must be stopped. If none of the interfaces to the common subnet are configured as primary, a primary interface is selected by OMROUTE. Valid values are Backup and Primary.

Tip: For IPv6, OMROUTE considers two interfaces to be on the same link if they have any prefixes in common.

Retransmit Parameters

The following parameters are used by OMPROUTE to set values in the routes added to the TCP/IP route table, which use this interface. The values affect the TCP retransmit algorithms. When TCP packets are not acknowledged, TCP begins to retransmit these packets at certain time intervals. If these packets are not acknowledged after a certain number of retransmits, TCP aborts the connection. The time interval between retransmissions increases by approximately twice the previous interval until the packets are acknowledged or the connection times out.

The time intervals between retransmissions and the number of times packets are retransmitted before the connection times out differs for initial connection establishment and for data packets. For initial connection establishment, the initial time interval is set at approximately 3 seconds, and the SYN packet is retransmitted 5 times before the connection is timed out. Data packets use a smoothed Round Trip Time (RTT) as the initial time interval and are retransmitted 15 times before the connection is timed out. All of the following parameters affect the data packet retransmission algorithm. Only the Min_Xmit_time parameter affects the initial connection establishment.

Tip: A new route lookup is performed after every two retransmissions for a data packet. For more information about the route lookup process, see [Route selection algorithm in z/OS Communications Server: IP Configuration Guide](#). Be careful when you design networks with firewalls. A firewall in an alternate routing path can generate a RESET packet for the rerouted data packets, which causes TCP to abort the connection.

Max_Xmit_Time

Limits the TCP retransmission interval. Decreasing this value might decrease the total time it takes a connection to time out. Specifying Max_Xmit_Time assures that the interval time never exceeds the specified limit. The minimum value that can be specified for Max_Xmit_Time is 0. The maximum is 999.990. The default is 120 seconds. This parameter affects the initial connection establishment retransmission timeout for all APIs, except the Pascal API (TcpOpen), that are using the socket connect function.

Min_Xmit_Time

Sets a minimum retransmit interval. Increasing this value might increase the amount of time it takes for TCP to time out a connection. The minimum value that can be specified for Min_Xmit_Time is 0. The maximum is 99.990. The default is 0.5 (500 milliseconds).

RT_Gain

This value is the percentage of the latest Round Trip Time (RTT) to be applied to the smoothed RTT average. The higher this value, the more influence the latest packet's RTT has on the average. The minimum value that can be specified for RT_Gain is 0. The maximum value is 1.0. The default is 0.125. This parameter does not affect initial connection retransmission.

Variance_Gain

This value is the percentage of the latest RTT variance from the RTT average to be applied to the RTT variance average. The higher this value, the more influence the latest packet's RTT has on the variance average. The minimum value that can be specified for Variance_Gain is 0. The maximum value is 1.0. The default is 0.25. This parameter does not affect initial connection retransmission.

Variance_Mult

This value is multiplied against the RTT variance in calculating the retransmission interval. The higher this value, the more affect variation in RTT has on calculating the retransmission interval. The minimum value that can be specified for Variance_Mult is 0. The maximum value is 99.990. The default is 2. This parameter does not affect initial connection retransmission.

Delay_Acks

The delay acknowledgments value that is added to the routing tables for routes that use this interface. Specify YES to delay transmission of acknowledgments when a packet is received with the PUSH bit on in the TCP header. Specify NO to return acknowledgments immediately when a packet is received with the PUSH bit on in the TCP header. This parameter affects only connections that use the routes associated with this interface.

Even if you specify YES, you can override the delay acknowledgments behavior can be overridden by specifying the NODELAYACKS parameter on the TCP/IP stack PORT, PORTRANGE, or TCPCONFIG

Valid values are YES and NO. The default value is YES.

Use the `IPv6_RANGE` statements to ad ranges to IPv6 OSPF areas. External to the area, a single route is advertised for each address range. For example, if an IPv6 OSPF area were to consist of the prefix `2001:0db8:1:2::/64`, all addresses falling within that prefix would be defined as consisting of a single address range. The address range would be specified as an address of `2001:0db8:1:2::` together with a prefix length of 64. Outside of the area, all addresses that fall within that prefix would be advertised as a single route to prefix `2001:0db8:1:2::/64`.

There are two choices:

- Ranges cannot be used for areas that serve as transit areas for virtual links. Also, when ranges are defined for an area, OSPF does not function correctly if the area is partitioned but is connected by the backbone.

Diagram illustrating the structure of the `IPv6_Range` structure:

- `IPv6_Range` is followed by `Prefix`, which is equal to `prefix/prefixlen`.
- A brace groups `Area_Number=0.0.0.0` and `Area_Number`, which is equal to `area`.
- Below this, another brace groups `Advertise=YES` and `Advertise`, which is equal to `value`.

Area Number

Advertise

IPv6_VIRTUAL_LINK statement

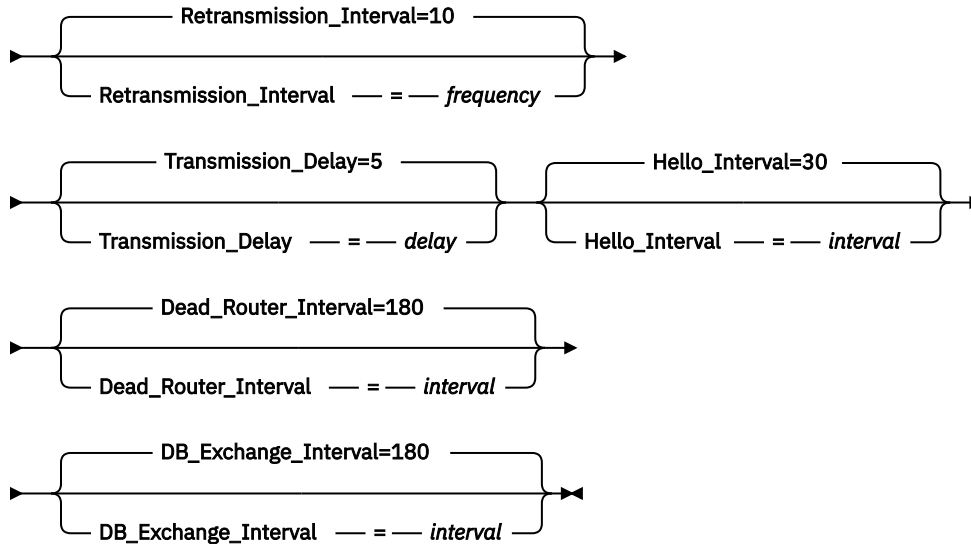

470 z/OS Communications Server: z/OS Communications Server: IP Configuration Reference

Virtual links can be configured between any two backbone routers that have an interface to a common nonbackbone, nonstub area. Virtual links are used to maintain backbone connectivity and must be configured at both endpoints.

Tip: Do not confuse OSPF virtual links with Virtual IP Address support (VIPA).

Syntax

➤➤ IPv6_Virtual_Link — Virtual_Endpoint_RouterID — = — *id* — Links_Transit_Area — = — *area* ➔

Parameters

Virtual_Endpoint_RouterID

32-bit IPv6 OSPF router ID of the virtual neighbor (other endpoint), specified in dotted-decimal notation.

Links_Transit_Area

This is the nonbackbone, nonstub area through which the virtual link is configured. Virtual links can be configured between any two area border routers that have an interface to a common nonbackbone and nonstub area. Virtual links must be configured in each of the link's two endpoints. Valid values are 0.0.0.1 - 255.255.255.255.

Retransmission_Interval

Sets the frequency (in seconds) of retransmitting link-state update packets, link-state request packets, and database description packets. Valid values are from in the range 1 - 65 535 seconds.

Guideline: If this parameter is set too low, needless retransmissions occur that could affect performance and interfere with neighbor adjacency establishment. It should be set to a higher value for a slower machine.

Transmission_Delay

This parameter is an estimate of the number of seconds that it takes to transmit link-state information over the virtual link. Each link-state advertisement has a finite lifetime of one hour. As each link-state advertisement is sent out from this virtual link, it is aged by this configured transmission delay. Valid values are in the range 1 - 65 535 seconds.

Hello_Interval

This parameter defines the number of seconds between OSPF Hello packets being sent out from this virtual link. Valid values are in the range 1 - 255 seconds. The Hello_Interval should be set higher than the same value used on the intervening, actual IPv6 OSPF interfaces.

Dead_Router_Interval

The interval in seconds, after not having received an OSPF Hello, that the neighbor is declared to be down. This value must be larger than the Hello_Interval. Valid values are 2 - 65 535. The dead router interval should be set higher than the same value used on the intervening, actual, IPv6 OSPF interfaces.

DB_Exchange_Interval

The interval in seconds that the database exchange process cannot exceed. If the interval elapses, the procedure is restarted. This value must be larger than the Hello_Interval. If no value is specified, the DB_Exchange_Interval is set to the Dead_Router_Interval. Valid values are 2 - 65 535.

IPv6 RIP configuration statements

This topic contains descriptions of the following IPv6 RIP configuration statements:

- IPV6_ACCEPT_RIP_ROUTE
- IPV6_RIP_FILTER
- IPV6_IGNORE_RIP_NEIGHBOR
- IPV6_ORIGINATE_RIP_DEFAULT
- IPV6_RIP_INTERFACE
- IPV6_RIP_SEND_ONLY

IPv6_ACCEPT_RIP_ROUTE statement

Allows a prefix or host route to be accepted independent of whether the interface it was received on has the corresponding reception parameter enabled (prefix or host). Routes added in this manner can be thought of as a list of exception conditions.

Syntax

➤ IPV6_Accept_RIP_Route — IP-address — = — *address* ➤

Parameters

IP_address

Destination route to be unconditionally accepted, specified in colon-hexadecimal format.

IPv6_RIP_FILTER statement

Use the IPV6_RIP_FILTER statement to allow for the specification of routes that are not to be sent or received over IPv6 RIP interfaces. The IPV6_RIP_Filter statement can be coded stand-alone in the OMROUTE configuration file (nosend and noreceive only) to apply to all configured IPv6 RIP interfaces.

Syntax

➤ IPV6_RIP_Filter= (*type,dest/prefix_len*) ➤

Parameters

type

The type can be any of the following values:

nosend

Specifies that routes matching the `dest` and `prefix_len` are not to be sent over IPv6 RIP interfaces. This option serves as an IPv6 RIP output filter.

noreceive

Specifies that routes matching the `dest` and `prefix_len` are to be ignored in messages received over IPv6 RIP interfaces. This option serves as an IPv6 RIP input filter.

dest

The `dest` specifies the destination route in colon-hexadecimal format. Alternatively, an asterisk (*), which matches *any* IPv6 destination, can be coded to filter out all routes sent or received over an interface. The use of the asterisk is also referred to as a blackhole filter. This should be used in conjunction with either additional `send` or `receive` filters to allow only certain routes to be received, or advertised over an interface or set of interfaces.

Tip: The blackhole `nosend` filter does not filter out the sending of the default route when the `IPv6_Originate_RIP_Default` statement is also configured.

prefix_len

The `prefix_len` specifies the number of significant bits in the destination to be filtered. If not coded, the default `prefix_len` is 128, meaning apply the filter to the `dest` as coded. Coding the `prefix_len` has no meaning and is not valid if the `dest` is coded as an asterisk (*) for a blackhole filter.

IPv6_IGNORE_RIP_NEIGHBOR statement

Use the `IPv6_IGNORE_RIP_NEIGHBOR` statement to specify that IPv6 RIP routing table messages from the specified gateway are to be ignored. This option serves as an IPv6 RIP input filter.

Syntax

➤ `IPv6_Ignore_Rip_Neighbor` — `IP_address= link_local_address` ➤

Parameters**IP_address**

Specifies the link-local IP address, in colon-hexadecimal format, of the gateway from which routing table messages are ignored. For multiple IP addresses, the statement must be repeated for each IP address.

IPv6_ORIGINATE_RIP_DEFAULT statement

Indicates under what conditions IPv6 RIP supports Default route (`destination/prefix_len ::/0`) generation.

Guideline: This statement determines whether or not a default route is considered available by OMPROUTE IPv6 RIP. The `SEND_DEFAULT_ROUTES` parameter on the `IPV6_RIP_INTERFACE` statement determines whether or not an available default route is advertised by a particular IPv6 RIP interface.

Syntax

➤ `IPv6_Originate_RIP_Default` —

Condition=Always

Condition
=
condition

Cost=1

Cost
=
cost

 ➤

Accept_Default=NO

Accept_Default
=
value

 ➤

Parameters

Condition

Condition for when IPv6 RIP is to advertise this router as a default router. Valid values are:

Always

Always originate IPv6 RIP default. This is the default value.

Never

Never advertise this router as a default IPv6 RIP router.

OSPF

Advertise this router as a default IPv6 RIP router if there are any IPv6 OSPF routes available.

Cost

Specifies the cost that IPv6 RIP advertises with the default route that it originates. Valid values are in the range 1 - 16. The default value is 1.

Accept_Default

Specifies whether or not OMPROUTE IPv6 RIP accepts default routes from inbound IPv6 RIP packets whose cost is higher than default routes originated by the host.

Tip: OMPROUTE IPv6 RIP always accepts default routes from inbound IPv6 RIP packets whose cost is lower than default routes originated by the host.

A value of YES indicates that OMPROUTE IPv6 RIP replaces this router's originated default route with a default route learned from inbound IPv6 RIP packets, even if that learned default route has a higher cost than this router's originated default route.

Result: When YES is coded, this router's originated default route is only used if no other default routes are learned from inbound IPv6 RIP packets.

A value of NO indicates that OMPROUTE IPv6 RIP replaces this router's originated default route with a default route learned from inbound IPv6 RIP packets only when the learned IPv6 RIP route has a lower cost than this router's originated default route. This is the default value.

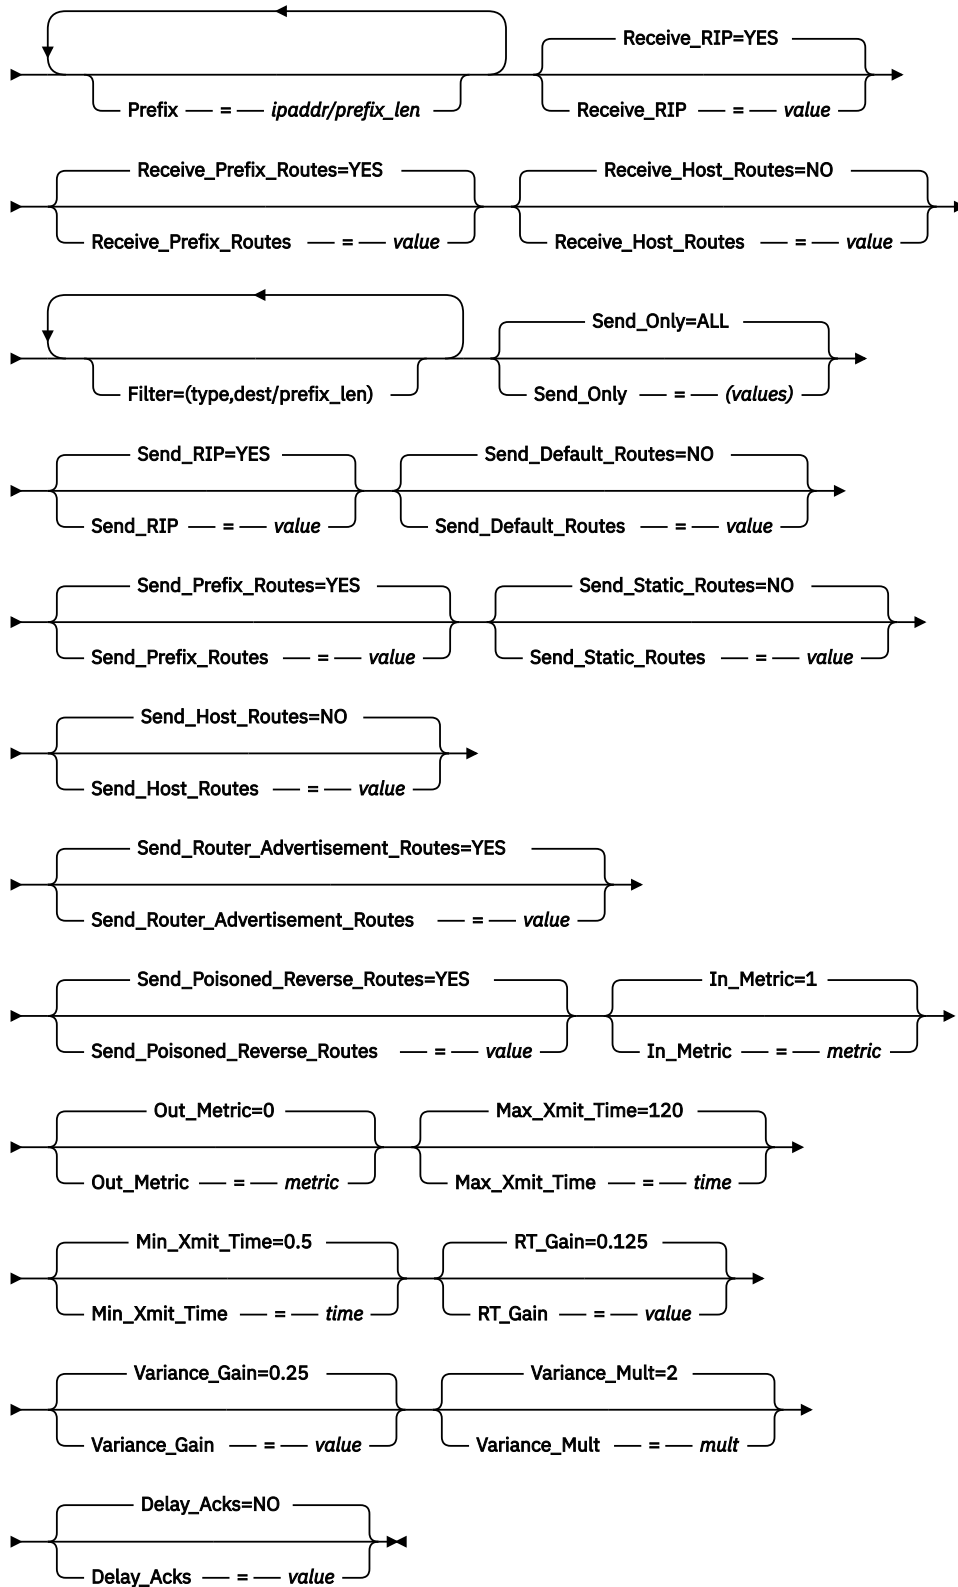

Result: When this parameter value is **NO** (either coded or by default), and the other parameters in this statement take their default values (CONDITION=ALWAYS and COST=1), OMPROUTE IPv6 RIP never accepts default routes learned from IPv6 RIP packets because it is not possible to learn an IPv6 RIP route whose cost is less than 1.

IPv6_RIP_INTERFACE statement

Use the IPv6_RIP_INTERFACE statement to configure the IPv6 RIP parameters for each IP interface. Replicate this statement in the configuration file for each IP interface over which IPv6 RIP operates.

Syntax

➤ IPv6_RIP_Interface — Name — = — *interface_name* ➔

Parameters

Name

The name of the interface. This name must match the interface name coded on the INTERFACE statement in the TCP/IP profile. Valid values are any character string of 1 - 16 characters in length. Wildcard names (terminating in *) can be coded. For example, OSAQDIO* would match stack interfaces named OSAQDIO1, OSAQDIO2, OSAQDIOABC, and so on.

Tips:

- For more information about how wildcard interfaces are parsed, see the [step about defining IPv6 interfaces in z/OS Communications Server: IP Configuration Guide](#).
- For the names to use when defining IPv6 dynamic XCF interfaces, see the routing information in [z/OS Communications Server: IP Configuration Guide](#).

Prefix

Specifies a prefix that is on the link to which the interface attaches. For each configured Prefix parameter, OMPROUTE adds a direct route to the prefix identified by the first *prefixlen* bits of *ipaddr*. Valid values for *ipaddr* are any valid colon-hexadecimal IPv6 address. Valid values for *prefixlen* are in the range 1 - 127. The prefix identified by the first *prefixlen* bits of *ipaddr* must not be a multicast prefix, a link-local prefix, or all zeros.

Guideline: If IPv6 Router Discovery is in use by the routers on the link, prefixes being advertised as on-link by the routers by way of Router Discovery should not be configured using this keyword. However, if IPv6 Router Discovery is not in use by the routers on the link or there is a need to supplement the list of prefixes being advertised as on-link by the routers, this keyword can be used. If the same prefix is configured using this keyword and learned from Router Discovery, the route in the TCP/IP stack's route table is the route added by OMPROUTE as a result of this keyword being specified. Any route for the same prefix that is learned from Router Discovery is ignored as long as the OMPROUTE route exists.

Receive_RIP

Specifies whether IPv6 RIP updates are accepted over this interface. Valid values are:

YES

IPv6 RIP packets are received over this interface, subject to other filters. This is the default value.

NO

No IPv6 RIP packets are received over this interface, regardless of any other filters.

Receive_Prefix_Routes

Specifies whether or not to learn routes for prefixes over this interface. If this is not set, only prefixes explicitly allowed using the IPv6_Accept_RIP_Route configuration statement are accepted on this interface. Valid values are YES or NO.

Receive_Host_Routes

Specifies whether or not to learn routes for hosts over this interface. If this is not set, only hosts explicitly allowed using the IPv6_Accept_RIP_Route configuration statement are accepted on this interface. Valid values are YES or NO.

filter

Multiple filter parameters can be coded on a IPv6_RIP_Interface statement. When specified on the IPv6_RIP_Interface statement, the filter parameter applies only to the corresponding IPv6 RIP interface. The IPv6_RIP_Filter statement can also be coded stand-alone in the OMPROUTE configuration file (nosend and noreceive only) to apply to all configured IPv6 RIP interfaces.

The type can be any of the following values:

Value

Description

nosend

Specifies that routes matching the *dest* and *prefix_len* are not to be sent over this interface. This option serves as an IPv6 RIP output filter.

noreceive

Specifies that routes matching the *dest* and *prefix_len* are to be ignored in messages received over this interface. This option serves as an IPv6 RIP input filter.

send

Specifies that routes matching the *dest* and *prefix_len* are to be sent over only this interface (or any other IPv6 RIP interface with an equivalent filter). This option serves as an IPv6 RIP output filter and can be used for inbound and outbound traffic splitting.

send_cond

Specifies that routes matching the *dest* and *prefix_len* are to be sent over only this interface when this interface is active (or any other active IPv6 RIP interface with an equivalent filter). If this interface is inactive, the routes can be sent over other interfaces. This option serves as an IPv6 RIP output filter and can be used for inbound and outbound traffic splitting.

receive

Specifies that routes matching the *dest* and *prefix_len* are to be received over only this interface (or any other IPv6 RIP interface with an equivalent filter). If received over other IPv6 RIP interfaces, the routes are discarded. This option serves as an IPv6 RIP input filter.

receive_cond

Specifies that routes matching the *dest* and *prefix_len* are to be received over only this interface when this interface is active (or any other active IPv6 RIP interface with an equivalent filter). If this interface is inactive, the routes can be received over all other active IPv6 RIP interfaces. This option serves as an IPv6 RIP input filter.

The *dest* specifies the destination route in colon-hexadecimal format. Alternatively, an asterisk (*) can be coded in conjunction with the *nosend* and *noreceive* filter types. This serves as a blackhole filter that can be used to filter out all routes sent or received over an interface. This should be used in conjunction with either additional *send* or *receive* filters to allow only certain routes to be received, or advertised over an interface or set of interfaces.

Tip: If the blackhole *nosend* filter is used, it does not filter out the sending of the default route when the *Originate_RIP_Default* statement is also configured.

The *prefix_len* specifies the number of significant bits in the destination to be filtered. If not coded, the default *prefix_len* is 128, meaning apply the filter to the *dest* route as coded. Coding the *prefix_len* has no meaning and is not valid if the *dest* is coded as an asterisk (*) for a blackhole filter.

Send_Only

Specifies send restrictions. Multiple values can be coded by separating the values with commas, unless ALL is coded. The valid values are:

ALL

Specifies no send restrictions.

VIRTUAL

Sends virtual IP addresses.

DEFAULT

Sends the default route.

DIRECT

Sends direct routes.

TRIGGERED

Only sends routes when requested or when a route becomes inactive (metric 16).

VIRTUAL, DEFAULT, and DIRECT are OR'd together to determine what should be sent. Thus, coding *SEND_ONLY*=(VIRTUAL, DEFAULT) sends virtual IP addresses and the default route. When ALL is coded, it must not be enclosed within parentheses. When any of the other possible values are coded, they must be enclosed within parentheses.

When specified on the *IPv6_RIP_Interface* statement, the *Send_Only* parameter applies only to the corresponding IPv6 RIP interface. The *IPv6_RIP_Send_Only* statement can also be coded stand-alone in the *OMPROUTE* configuration file to apply to all IPv6 RIP interfaces.

Send_RIP

Determines whether or not IPv6 RIP advertisements are sent over this interface. Valid values are YES or NO.

Send_Default_Routes

Advertise the default route (destination/prefix_len ::/0), if it is available, in IPv6 RIP responses sent from this IP source address. Valid values are YES or NO. If DEFAULT is coded on the Send_Only parameter or the stand-alone IPv6_RIP_Send_Only statement, the Send_Default_Routes parameter is ignored and is set to YES.

Send_Prefix_Routes

Advertise all prefix routes in IPv6 RIP responses sent from this IP address. Valid values are YES or NO.

Send_Static_Routes

Advertise static and direct routes in IPv6 RIP responses sent from this IP source address. Split horizon is applied; that is, static routes configured over an interface are not included in IPv6 RIP responses sent from that interface. Valid values are YES or NO.

Send_Host_Routes

Advertise host routes in IPv6 RIP responses sent from this IP source address. In this context, a host route is one with a prefix length of 128. Valid values are YES or NO.

Send_Router_Advertisement_Routes

Advertise router advertisement routes in IPv6 RIP responses sent from this IP source address. These are routes that have been learned by the stack using IPv6 Router Discovery and that OMPROUTE has learned from the stack. Split horizon is applied; that is, router advertisement routes learned over an interface are not included in IPv6 RIP responses sent from that interface. Valid values are YES or NO.

Send_Poisoned_Reverse_Routes

Advertise poisoned reverse routes over the interface corresponding to the next hop. A poison reverse route is one with an infinite metric (16). Valid values are YES or NO. If NO is specified, OMPROUTE still uses split horizon.

In_Metric

Specifies the value of the metric to be added to IPv6 RIP routes received over this interface prior to installation in the routing table. Valid values are in the range 1 - 15.

Out_Metric

Specifies the value of the metric to be added to IPv6 RIP routes advertised over this interface. Valid values are in the range 0 - 15.

Retransmit Parameters

The following parameters are used by OMPROUTE to set values in the routes added to the TCP/IP route table which use this interface. The values affect the TCP retransmit algorithms. When TCP packets are not acknowledged, TCP begins to retransmit these packets at certain time intervals. If these packets are not acknowledged after a certain number of retransmits, TCP aborts the connection. The time interval between retransmissions increases by approximately twice the previous interval until the packets are acknowledged or the connection times out.

The time intervals between retransmissions and the number of times packets are retransmitted before the connection times out differs for initial connection establishment and for data packets. For initial connection establishment, the initial time interval is set at approximately 3 seconds, and the SYN packet is retransmitted 5 times before the connection is timed out. Data packets use a smoothed Round Trip Time (RTT) as the initial time interval and are retransmitted 15 times before the connection is timed out. All of the following parameters affect the data packet retransmission algorithm. Only the Min_Xmit_Time parameter affects the initial connection establishment.

Tip: A new route lookup is performed after every two retransmissions for a data packet. For more information about the route lookup process, see [Route selection algorithm in z/OS Communications Server: IP Configuration Guide](#). Be careful when you design networks with firewalls. A firewall in an alternate routing path can generate a RESET packet for the rerouted data packets, which causes TCP to abort the connection.

Max_Xmit_Time

Limits the TCP retransmission interval. Decreasing this value might decrease the total time it takes a connection to time out. Specifying Max_Xmit_Time assures that the interval time never exceeds the specified limit. The minimum value that can be specified for Max_Xmit_Time is 0. The maximum is 999.990. The default is 120 seconds. This parameter affects the initial connection establishment retransmission timeout for all APIs, except the Pascal API (TcpOpen), that are using the socket connect function.

Min_Xmit_Time

Sets a minimum retransmit interval. Increasing this value might increase the amount of time it takes for TCP to time out a connection. The minimum value that can be specified for Min_Xmit_Time is 0. The maximum is 99.990. The default is 0.5 (500 milliseconds).

RT_Gain

This value is the percentage of the latest Round Trip Time (RTT) to be applied to the smoothed RTT average. The higher this value, the more influence the latest packet's RTT has on the average. The minimum value that can be specified for RT_Gain is 0. The maximum value is 1.0. The default is 0.125. This parameter does not affect initial connection retransmission.

Variance_Gain

This value is the percentage of the latest RTT variance from the RTT average to be applied to the RTT variance average. The higher this value, the more influence the latest packet's RTT has on the variance average. The minimum value that can be specified for Variance_Gain is 0. The maximum value is 1.0. The default is 0.25. This parameter does not affect initial connection retransmission.

Variance_Mult

This value is multiplied against the RTT variance in calculating the retransmission interval. The higher this value, the more affect variation in RTT has on calculating the retransmission interval. The minimum value that can be specified for Variance_Mult is 0. The maximum value is 99.990. The default is 2. This parameter does not affect initial connection retransmission.

Delay_Acks

The delay acknowledgments value that is added to the routing tables for routes that use this interface. Specify YES to delay transmission of acknowledgments when a packet is received with the PUSH bit on in the TCP header. Specify NO to return acknowledgments immediately when a packet is received with the PUSH bit on in the TCP header. This parameter affects only connections that use the routes associated with this interface.

Even if you specify YES, you can override the delay acknowledgments behavior can be overridden by specifying the NODELAYACKS parameter on the TCP/IP stack PORT, PORTRANGE, or TCPCONFIG profile statements. A value of NO can override the specification of the DELAYACKS parameter on the TCP/IP stack PORT, PORTRANGE, and TCPCONFIG profile statements.

Valid values are YES and NO. The default value is YES.

IPv6_RIP_SEND_ONLY statement

Use the IPv6_RIP_SEND_ONLY statement to allow for the specification of the types of routes that are to be included in advertisements sent over IPv6 RIP interfaces. The IPv6_RIP_Send_Only statement can be coded stand-alone in the OMPROUTE configuration file to apply to all IPv6 RIP interfaces.

Syntax

Parameters

(values)

Specifies send restrictions. Multiple values can be coded by separating the values with commas, unless ALL is coded. The valid values are:

ALL

Specifies no send restrictions.

VIRTUAL

Sends virtual IP addresses.

DEFAULT

Sends the default route.

DIRECT

Sends direct routes.

TRIGGERED

Only sends routes when requested or when a route becomes inactive (metric 16).

VIRTUAL, DEFAULT, and DIRECT are OR'd together to determine what should be sent. Thus, coding SEND_ONLY=(VIRTUAL, DEFAULT) sends virtual IP addresses and the default route. When ALL is coded, it must not be enclosed within parentheses. When any of the other possible values are coded, they must be enclosed within parentheses.

When specified on the IPv6_RIP_Send_Only statement in the OMPROUTE configuration file, this statement applies to all IPv6 RIP interfaces. The SEND_ONLY parameter can also be coded on the IPv6_RIP_Interface statement. When specified on the IPv6_RIP_Interface statement, the SEND_ONLY parameter applies only to the corresponding IPv6 RIP interface.

Common configuration statements for RIP and OSPF

This topic contains descriptions of the common configuration statements:

- DEFAULT_ROUTE
- ROUTESA_CONFIG
- INTERFACE
- GLOBAL_OPTIONS
- IPV6_DEFAULT_ROUTE
- IPV6_INTERFACE

DEFAULT_ROUTE statement

Use the DEFAULT_ROUTE statement to specify IPv4 default routes to OMPROUTE. Default routes are created in the following ways:

- Specify a BEGINROUTES statement in the TCP/IP profile for a default route in the main route table
- Specify a Policy Agent RouteTable statement for a default route in a policy-based route table
- Specify a Default_Route statement
- Let the default route be learned by routing protocol

You can configure up to 16 default routes using the DEFAULT_ROUTE statement. Each default route is added to the main route table. A default route is also added to any policy-based route tables if the interface and next-hop values associated with the default route are compatible with the dynamic routing parameters defined for those route tables. The Send_Default_Routes keyword on the RIP_Interface statement indicates whether the default routes over that interface should be advertised.

Syntax

Parameters

Name

The name of the interface used in the default route. This name must match a link name coded on the HOME statement or the interface name coded on an IPv4 INTERFACE statement in the TCP/IP profile. The name can be any 16 characters.

Restriction: VIPA interfaces cannot be used for the *interface_name* value.

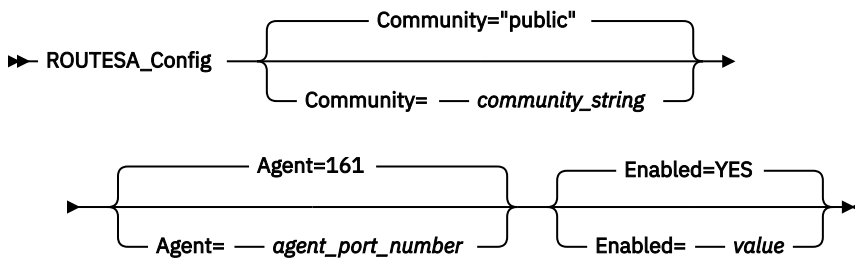

Next_Hop

IP address of the next hop used in the default route.

ROUTESA_CONFIG statement

Use the ROUTESA_CONFIG statement to configure the OMPROUTE OSPF subagent.

Syntax

Parameters

Community

A character string of 1 - 32 characters enclosed in double quotation marks (") used as the community name (or password) in establishing contact with the SNMP agent. For the OMPROUTE subagent to communicate with the z/OS Communications Server SNMP agent, the community name specified on the COMMUNITY keyword must match one that is defined in the PW.SRC or SNMPD.CONF data set configured to the SNMP agent or the -c parameter when the SNMP agent is started.

For more information about how the community name is used to permit access to the SNMP agent, see [Step 1: Configure the SNMP agent \(OSNMPD\)](#), in [z/OS Communications Server: IP Configuration Guide](#). The default value is public.

Tip: The community name is case sensitive.

Agent

A port number in the range 1 - 65 535 used in establishing communication with the SNMP agent. For the OMPROUTE subagent to communicate with the z/OS Communications Server SNMP agent, the port number specified must match the port number specified on the -p parameter when the SNMP agent is started. The default value is 161.

Enabled

A value of YES indicates that the OMPROUTE subagent should be started during OMPROUTE initialization. If there are no active OSPF interfaces, the OMPROUTE subagent returns *noSuchInstance* for all GET and GETNEXT requests. By default, the OMPROUTE subagent is started when OMPROUTE is started.

A value of NO indicates that the OMPROUTE subagent should not be started. Specify this keyword if little or no OSPF SNMP data is requested from this OSPF image. SNMP MIB objects supported by the TCP/IP SNMP agent and TCP/IP subagent (other than the OMPROUTE subagent) are still available. For information about which MIB objects are supported by the SNMP agent and OMPROUTE subagent, see the [z/OS Communications Server: IP User's Guide and Commands](#).

Examples

```
ROUTESA_CONFIG COMMUNITY="USACCESS" AGENT=528  
ROUTESA_CONFIG ENABLED=NO
```

Usage notes

- If ENABLED=NO is specified, the OMPROUTE subagent is *not* started during OMPROUTE initialization. If the ROUTESA_CONFIG statement itself is *not* specified, the OMPROUTE subagent is started (this is the default).
- The community string is case sensitive and must be 1 - 32 characters. It is not converted to uppercase by profile processing.
- A MODIFY command can be used to start or stop the OMPROUTE subagent, but the setting of the parameters cannot be changed unless OMPROUTE is recycled.

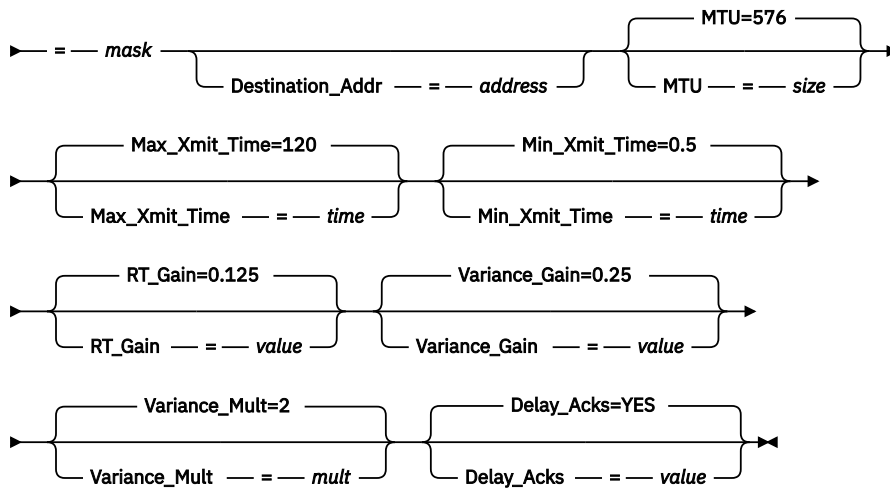

INTERFACE statement

Use the INTERFACE statement to allow certain values to be specified for generic IPv4 interfaces, which are interfaces that are neither OSPF nor RIP interfaces. Each IPv4 interface that is neither an OSPF nor an RIP interface should be configured to OMPROUTE using the INTERFACE statement unless it is a non-point-to-point interface and the default values for Subnet_Mask and MTU are acceptable for that interface.

Tip: To display information about INTERFACES, use the **d tcpip,tcpname, OMP,GENERIC** commands.

Syntax

►► Interface — IP_address — = — *ip_address* — Name — = — *interface_name* — Subnet_Mask —►

Parameters

IP_address

The IP address can be a valid IP address that is configured on the system or it can be specified with asterisks (*) as wildcards. The valid wildcard specifications are below. The result of coding a wildcard value is that all configured interfaces whose IP address matches the wildcard are configured as interfaces. Configured interface IP addresses and names are matched against possible wildcards in the order they appear below with the name and any matching wildcard being the best match, x.y.z.* being second best, and so forth.

```
interface name and any matching wildcard
x.y.z.*
x.y.*.*
x.*.*.*
*.*.*.* - Same as ALL
ALL - Same as *.*.*.*
```

Tip: For more information about how wildcard interfaces are parsed, see this [Method of assigning interface definitions to stack interfaces \(wildcard and explicit\): in z/OS Communications Server: IP Configuration Guide](#).

Because a stack could have a large number of Dynamic VIPAs (DVIPAs) defined, as well as DVIPA ranges, additional wildcard capabilities exist on the INTERFACE statement for use only with DVIPAs. Ranges of DVIPA interfaces can be defined using the subnet mask parameter on the INTERFACE statement. The range defined in this way is all the IP addresses that fall within the subnet defined by the mask and the IP address.

When this type of wildcarding is being used, the value of the IP_ADDRESS parameter must be the subnet number of the range. For example, the following code defines a range of six addresses (9.67.101.9 to 9.67.101.14) that can be used for DVIPA addresses and matches any DVIPA interface that fall into the 9.67.101.8/29 subnet:

```
IP_ADDRESS= 9.67.101.8
SUBNET_MASK= 255.255.255.248
```

Alternatively, the following code is not because 9.67.101.17 is an address within the subnet range, not the subnet number itself (that would be 9.67.101.16). This second definition only matches an interface whose home address is 9.67.101.17.

```
IP_ADDRESS= 9.67.101.17
SUBNET_MASK=255.255.255.248
```

Name

The name of the interface. A valid value is any string 1 - 16 characters in length.

Rules:

- If this is not a wildcard interface definition, the name must match the link name that is coded for the corresponding IP address on the HOME statement or the interface name coded for the corresponding IPv4 INTERFACE statement in the TCP/IP profile.
- If this is a wildcard interface definition, then this parameter is used in conjunction with the defined wildcard IP address when searching for definitions to match a stack interface. For more details about this process, see [Method of assigning interface definitions to stack interfaces \(wildcard and explicit\)](#): in [z/OS Communications Server: IP Configuration Guide](#).

For Dynamic VIPA (DVIPA), link names are assigned programmatically by the stack when the DVIPA is created; therefore, the name field set on the INTERFACE statement is ignored by OMPROUTE for DVIPAs.

Subnet_Mask

Subnet mask for the associated interface's IP address. If you configure this interface in the TCP/IP profile using the IPv4 INTERFACE statement and you configure a subnet mask on that statement that does not match the value that you specify on this parameter, OMPROUTE issues message EZZ8164I and uses this subnet mask.

Destination_Addr

IP address of the host at the remote end of this interface. This parameter is valid only for point-to-point links. If this parameter is not specified for a point-to-point link, a route to the host at the remote end of the interface is not added to the appropriate TCP/IP route tables (main and policy-based tables). A subnet route for the interface is added when OMPROUTE is initialized whether or not this parameter is specified.

MTU

The maximum transmission unit size that OMPROUTE adds to the appropriate routing tables (main and policy-based tables) for routes that use this interface. Valid values are in the range 0 - 65535. If you configure this interface in the TCP/IP profile using the IPv4 INTERFACE statement and you configure an MTU on that statement and the MTU that you configure on that statement does not match the MTU (the configured value or the default value) on this statement, OMPROUTE issues message EZZ8163I and uses the MTU value on this statement.

Tip: See [z/OS Communications Server: IP Configuration Guide](#), in section Maximum transmission unit considerations, for additional information about how TCP/IP uses the MTU to determine the largest size frame to send.

Retransmit Parameters

The following parameters are used by OMPROUTE to set values in the routes which use this interface that are added to the TCP/IP route tables. The values affect the TCP retransmit algorithms. When TCP packets are not acknowledged, TCP begins to retransmit these packets at certain time intervals. If these packets are not acknowledged after a certain number of retransmits, TCP aborts the connection. The time interval between retransmissions increases by approximately twice the previous interval until the packets are acknowledged or the connection times out.

The time intervals between retransmissions and the number of times packets are retransmitted before the connection times out differs for initial connection establishment and for data packets. For initial connection establishment, the initial time interval is set at approximately 3 seconds, and the SYN packet is retransmitted 5 times before the connection is timed out. Data packets use a smoothed Round Trip Time (RTT) as the initial time interval and are retransmitted 15 times before the connection is timed out. All of the following parameters affect the data packet retransmission algorithm. Only the Min_Xmit_Time parameter affects the initial connection establishment.

Tip: A new route lookup is performed after every two retransmissions for a data packet. For more information about the route lookup process, see [Route selection algorithm in z/OS Communications Server: IP Configuration Guide](#). Be careful when you design networks with firewalls. A firewall in an alternate routing path can generate a RESET packet for the rerouted data packets, which causes TCP to abort the connection.

Max_Xmit_Time

Limits the TCP retransmission interval. Decreasing this value might decrease the total time it takes a connection to time out. Specifying Max_Xmit_Time assures that the interval time never exceeds the specified limit. The minimum value that can be specified for Max_Xmit_Time is 0. The maximum is 999.990. The default is 120 seconds. This parameter affects the initial connection establishment retransmission timeout for all APIs, except the Pascal API (TcpOpen), that are using the socket connect function.

Min_Xmit_Time

Sets a minimum retransmit interval. Increasing this value might increase the amount of time it takes for TCP to time out a connection. The minimum value that can be specified for Min_Xmit_Time is 0. The maximum is 99.990. The default is 0.5 (500 milliseconds).

RT_Gain

This value is the percentage of the latest Round Trip Time (RTT) to be applied to the smoothed RTT average. The higher this value, the more influence the latest packet's RTT has on the average. The minimum value that can be specified for RT_Gain is 0. The maximum value is 1.0. The default is 0.125. This parameter does not affect initial connection retransmission.

Variance_Gain

This value is the percentage of the latest RTT variance from the RTT average to be applied to the RTT variance average. The higher this value, the more influence the latest packet's RTT has on the variance average. The minimum value that can be specified for Variance_Gain is 0. The maximum value is 1.0. The default is 0.25. This parameter does not affect initial connection retransmission.

Variance_Mult

This value is multiplied against the RTT variance in calculating the retransmission interval. The higher this value, the more affect variation in RTT has on calculating the retransmission interval. The minimum value that can be specified for Variance_Mult is 0. The maximum value is 99.990. The default is 2. This parameter does not affect initial connection retransmission.

Delay_Acks

The delay acknowledgments value that is added to the routing tables for routes that use this interface. Specify YES to delay transmission of acknowledgments when a packet is received with the PUSH bit on in the TCP header. Specify NO to return acknowledgments immediately when a packet is received with the PUSH bit on in the TCP header. This parameter affects only connections that use the routes associated with this interface.

Even if you specify YES, you can override the delay acknowledgments behavior can be overridden by specifying the NODELAYACKS parameter on the TCP/IP stack PORT, PORTRANGE, or TCPCONFIG profile statements. A value of NO can override the specification of the DELAYACKS parameter on the TCP/IP stack PORT, PORTRANGE, and TCPCONFIG profile statements.

Valid values are YES and NO. The default value is YES.

GLOBAL_OPTIONS statement

Use the GLOBAL_OPTIONS statement to configure miscellaneous options to OMPROUTE which apply to OSPF, RIP, or neither.

Syntax

Parameters

Ignore_Unknown_Interfaces

Instructs OMROUTE on how to handle stack interfaces that are not configured by way of OSPF_INTERFACE, RIP_INTERFACE, IPV6_RIP_INTERFACE, IPV6_OSPF_INTERFACE, INTERFACE, or IPV6_INTERFACE statements, either explicit or wildcard. NO indicates that OMROUTE configures such interfaces with default values (including setting the MTU size to 576 and using the class mask as the subnet mask and overriding stack definition values with these default values for IPv4 interfaces), and possibly advertises these interfaces to the rest of the network if OSPF settings or RIP filters permit it.

Result: By definition, the network class masks that are used for undefined IPv4 interfaces if GLOBAL_OPTIONS Ignore_Unknown_Interfaces=NO is coded, or the GLOBAL_OPTIONS statement is not coded, (thereby taking the default of NO) are as follows:

- Class A: 255.0.0.0
- Class B: 255.255.0.0
- Class C: 255.255.255.0

A YES value indicates that OMROUTE ignores these interfaces, does not configure them, and does not advertise them under any circumstances. IF YES is coded, OMROUTE does not advertise these interfaces or their attached subnets or prefixes, and it does not update any stack definition values. Static routes coded in the TCP/IP profile over interfaces that are ignored by OMROUTE are still advertised by OMROUTE into OSPF, RIP, or both if appropriate filters and settings permit the advertisement of static routes.

Guideline: Code YES to get additional reconfiguration capability. You can use OMROUTE reconfiguration to add a definition for an interface that has been defined to the stack but is ignored by OMROUTE. However, OMROUTE does not associate the interface with the new definition until it has been deleted from the stack and re-added.

IPv6_DEFAULT_ROUTE statement

Use the IPv6_DEFAULT_ROUTE statement to allow IPv6 default routes to be specified to OMROUTE. IPv6 default routes are created using any of the following methods:

- BEGINROUTES statement
- IPv6_Default_Route statement
- Learned by routing protocol
- Router advertisements

When IPv6 default routes are specified using more than one of these methods, the method that is used to create the default routes is determined according to the following list, in order of descending precedence:

1. Non-replaceable static default routes specified using the BEGINROUTES statement
2. Default routes learned by routing protocol
3. Default routes specified using the IPv6_Default_Route statement
4. Router advertisements
5. Replaceable static default routes specified using the BEGINROUTES statement

Up to 16 default routes can be configured using this IPv6_Default_Route statement. The Send_Default_Routes keyword on the IPv6_RIP_Interface statement indicates whether or not to advertise the IPv6 default routes over that interface.

Syntax

Parameters

Name

The name of the interface used in the default route. This name must match an interface name coded on the INTERFACE statement in the TCP/IP profile. Valid values are any 16 characters.

Restriction: You cannot use VIPA interfaces for the *interface_name* value.

Next_Hop

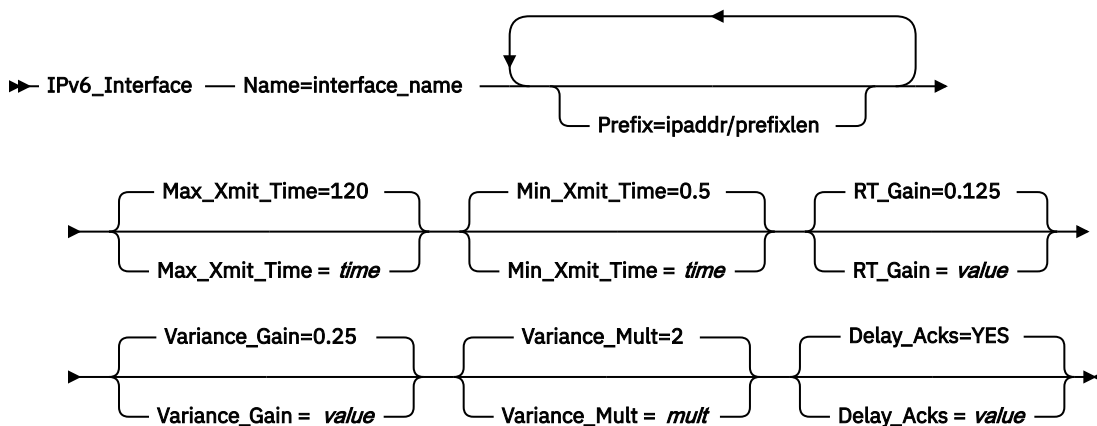

IP address of the next hop used in the default route, in colon-hexadecimal format. This IP address must be reachable using a direct route over the specified interface. If it is not, this next hop is not installed.

IPv6_INTERFACE statement

Use the IPv6_INTERFACE statement to allow certain values to be specified for generic IPv6 interfaces, which are interfaces that are neither IPv6 OSPF nor IPv6 RIP interfaces. If GLOBAL_OPTIONS is coded with IGNORE_UNDEFINED_INTERFACES=YES, then IPv6 interfaces that are not used for routing but that OMROUTE should be aware of should be coded in the OMROUTE configuration file. If that option is not coded, it is not necessary to code all non-routing IPv6 interfaces to OMROUTE if default values are acceptable and you do not need to code additional prefixes on the interface.

Tip: Use the d tcpip, tcpname, omroute, and generic6 commands to display information about IPv6_INTERFACES.

Syntax

Parameters

Name

The name of the interface. This name must match the interface name coded on the INTERFACE statement in the TCP/IP profile. Valid values are any character string of 1 - 16 characters in

length. Wildcard names (terminating in *) can be coded. For example, OSAQDIO* would match stack interfaces named OSAQDIO1, OSAQDIO2, OSAQDIOABC, and so on.

Tip: For more information about how wildcard interfaces are parsed, see the [step about defining IPv6 interfaces in z/OS Communications Server: IP Configuration Guide](#).

Prefix

Specifies a prefix that is on the link to which the interface attaches. For each configured Prefix parameter, OMROUTE adds a direct route to the prefix identified by the first *prefixlen* bits of *ipaddr*. Valid values for *ipaddr* are any valid colon-hexadecimal IPv6 address. Valid values for *prefixlen* are in the range 1 - 127. The prefix identified by the first *prefixlen* bits of *ipaddr* must not be a multicast prefix, a link-local prefix, or all zeros.

Guideline: If IPv6 Router Discovery is in use by the routers on the link, prefixes being advertised as on-link by the routers by way of Router Discovery should not be configured using this keyword. However, if IPv6 Router Discovery is not in use by the routers on the link or there is a need to supplement the list of prefixes being advertised as on-link by the routers, this keyword can be used. If the same prefix is configured using this keyword and learned from Router Discovery, the route in the TCP/IP stack's route table is the route added by OMROUTE as a result of this keyword being specified. Any route for the same prefix that is learned from Router Discovery is ignored as long as the OMROUTE route exists.

Retransmit Parameters

The following parameters are used by OMROUTE to set values in the routes added to the TCP/IP route table which use this interface. The values affect the TCP retransmit algorithms. When TCP packets are not acknowledged, TCP begins to retransmit these packets at certain time intervals. If these packets are not acknowledged after a certain number of retransmits, TCP aborts the connection. The time interval between retransmissions increases by approximately twice the previous interval until the packets are acknowledged or the connection times out.

The time intervals between retransmissions and the number of times packets are retransmitted before the connection times out differs for initial connection establishment and for data packets. For initial connection establishment, the initial time interval is set at approximately 3 seconds, and the SYN packet is retransmitted 5 times before the connection is timed out. Data packets use a smoothed Round Trip Time (RTT) as the initial time interval and are retransmitted 15 times before the connection is timed out. All of the following parameters affect the data packet retransmission algorithm. Only the Min_Xmit_Time parameter affects the initial connection establishment.

Tip: A new route lookup is performed after every two retransmissions for a data packet. For more information about the route lookup process, see [Route selection algorithm in z/OS Communications Server: IP Configuration Guide](#). Be careful when you design networks with firewalls. A firewall in an alternate routing path can generate a RESET packet for the rerouted data packets, which causes TCP to abort the connection.

Max_Xmit_Time

Limits the TCP retransmission interval. Decreasing this value might decrease the total time it takes a connection to time out. Specifying Max_Xmit_Time assures that the interval time never exceeds the specified limit. The minimum value that can be specified for Max_Xmit_Time is 0. The maximum is 999.990. The default is 120 seconds. This parameter affects the initial connection establishment retransmission timeout for all APIs, except the Pascal API (TcpOpen), that are using the socket connect function.

Min_Xmit_Time

Sets a minimum retransmit interval. Increasing this value might increase the amount of time it takes for TCP to time out a connection. The minimum value that can be specified for Min_Xmit_Time is 0. The maximum is 99.990. The default is 0.5 (500 milliseconds).

RT_Gain

This value is the percentage of the latest Round Trip Time (RTT) to be applied to the smoothed RTT average. The higher this value, the more influence the latest packet's RTT has on the average. The minimum value that can be specified for RT_Gain is 0. The maximum value is 1.0. The default is 0.125. This parameter does not affect initial connection retransmission.

Variance_Gain

This value is the percentage of the latest RTT variance from the RTT average to be applied to the RTT variance average. The higher this value, the more influence the latest packet's RTT has on the variance average. The minimum value that can be specified for Variance_Gain is 0. The maximum value is 1.0. The default is 0.25 . This parameter does not affect initial connection retransmission.

Variance_Mult

This value is multiplied against the RTT variance in calculating the retransmission interval. The higher this value, the more affect variation in RTT has on calculating the retransmission interval. The minimum value that can be specified for Variance_Mult is 0. The maximum value is 99.990. The default is 2. This parameter does not affect initial connection retransmission.

Delay_Acks

The delay acknowledgments value that is added to the routing tables for routes that use this interface. Specify YES to delay transmission of acknowledgments when a packet is received with the PUSH bit on in the TCP header. Specify NO to return acknowledgments immediately when a packet is received with the PUSH bit on in the TCP header. This parameter affects only connections that use the routes associated with this interface.

Even if you specify YES, you can override the delay acknowledgments behavior can be overridden by specifying the NODELAYACKS parameter on the TCP/IP stack PORT, PORTRANGE, or TCPCONFIG profile statements. A value of NO can override the specification of the DELAYACKS parameter on the TCP/IP stack PORT, PORTRANGE, and TCPCONFIG profile statements.

Valid values are YES and NO. The default value is YES.

Interfaces supported by OMROUTE

Table 27 on page 489, Table 28 on page 490, and Table 29 on page 490 show the types of interfaces supported by OMROUTE.

Table 27. Types of IPv4 interfaces (using DEVICE and LINK statements) supported by OMROUTE							
Interface type	Link type	Connectivity	Multi-access broadcast	Non-broadcast multiaccess (NBMA)	Point-to-point	Point-to-multi-point	Futile neighbor state loop detection support
CTC	CTC	z/OS through channel-channel adapter	No	No	Yes	No	No
MPCIPA: IPAQIDIO (for internal QDIO)	IPAQIDIO (for internal QDIO)	Another TCP/IP within same CPC	Yes	No	No	No	Yes
MPCPTP	MPCPTP	z/OS, pSeries, Cisco CIP, CS/NT, or OEM z/OS,	No	No	Yes	Yes	No
MPCPTP	MPCPTP (for XCF)	Another TCP/IP within same z/OS sysplex	No	No	Yes	Yes	No
MPCPTP (for IUTSAMEH)	MPCPTP (for IUTSAMEH)	Another TCP/IP within same z/OS sysplex	No	No	Yes	Yes	No

Table 27. Types of IPv4 interfaces (using *DEVICE* and *LINK* statements) supported by *OMPROUTE* (continued)

Interface type	Link type	Connectivity	Multi-access broadcast	Non-broadcast multiaccess (NBMA)	Point-to-point	Point-to-multi-point	Futile neighbor state loop detection support
Notes: <ol style="list-style-type: none"> 1. For more information about the <i>DEVICE</i> and <i>LINK</i> statements for the interfaces, see Figure 1 on page 36. 2. For more information about IPv4 interfaces using the <i>INTERFACE</i> statement, see Table 28 on page 490. 							

Table 28. Types of IPv4 interfaces (using *INTERFACE* statement) supported by *OMPROUTE*

Chapter 12. TN3270E Telnet server

This topic describes the TN3270E Telnet server (Telnet) parameter and mapping statements.

Telnet profile statements overview

These statements define the characteristics of connections, which host VTAM applications can be accessed, what LU name represents the client, and other functions. For a detailed discussion of Telnet functions, see [z/OS Communications Server: IP Configuration Guide](#).

TELNETGLOBALS statements

The TELNETGLOBALS block is an *optional* statement block that contains Telnet parameter statements that apply to all connections on all Telnet ports.

Use the following format in the PROFILE dataset:

TELNETPARMS statements

The TELNETPARMS block is a *required* statement block that contains Telnet parameter statements that apply to all connections of the Telnet port defined in the block. Use the following format in the PROFILE dataset:

PARMSGROUP statements

The PARMSGROUP Object statement is an *optional* statement that applies to connections which have the PARMSGROUP mapped by either their client identifiers or a matching LUMAP statement. Use the following format in the PROFILE dataset:

BEGINVTAM block

The BEGINVTAM block is a *required* block that contains Telnet mapping statements used to *map objects to clients based on Client Identifier*. Use the following format in the PROFILE dataset:

INCLUDE statement

The INCLUDE statement causes profile statements from the named data set to be included at the point that the INCLUDE statement is encountered.

Use the following format in the PROFILE dataset:

➤ INCLUDE — *data_set_name* ➤

Telnet statement syntax

The statement syntax is the same in the configuration data set specified on the PROFILE DD card and the VARY TCPIP,tproc,OBEYFILE command data set.

- A TELNETPARMS block and a BEGINVTAM block are required for each port.
- If a duplicate TELNETGLOBALS, TELNETPARMS for a port, BEGINVTAM for a port blocks, or PARMSGROUP name within a BEGINVTAM parameter is specified, the last statement block is used.
- If duplicate statements appear in the TELNETGLOBALS, TELNETPARMS, PARMSGROUP, or BEGINVTAM blocks, Telnet uses the last valid statement that was specified. However, if the REPLACEMENT statement is not valid, the statement being replaced is removed and replacement does not occur. This is referred to as the last one wins rule. The only exception to the last one wins rule is in the case of Client Identifiers defined in their respective group statement. For details, see [“Telnet mapping statements in the Telnet profile” on page 533](#).
- Do not use the name of a Profile statement or parameter as a variable name in a statement. For example, do not assign the names USSTCP to USS table. Do not use the value GENERIC as a PRTGROUP name.
- For update capability and procedures, see [z/OS Communications Server: IP Configuration Guide](#) for information about managing Telnet.
- An END statement terminates a number of statements, such as the LUGROUP statement. If the END statement is omitted, all subsequent tokens in the data set are interpreted as parameters for that configuration statement until another statement is found.
- In general, if a syntax error is encountered in a list of parameters, such as an LUGROUP list, the parameter in error is ignored and the remaining entries are processed.
- Profile statements have some order restrictions. Basically, any statement that references a that is name defined in another statement must follow that statement. For example, LUMAP statements must follow the IPGROUP statement that defines the IPGROUP statement that is referenced by the mapping.
- During configuration, Telnet ensures that names are the appropriate length. If a name is too long, Telnet issues a message and the statement fails.
- Error messages are issued for incorrect statements. A DEBUG message displays the profile line number of the statement in error and other pertinent information. Error messages can be turned off by coding DEBUG OFF or DEBUG SUMMARY in the TELNETGLOBALS statement.
- A semicolon begins a comment. Comments act as blanks, separating words without affecting their meaning.
- An argument followed by a comment must have a blank before the semicolon.
- Statements can be split across multiple lines.
- Sequence numbers are not allowed.

Rules: User-defined names on configuration statements must adhere to the following rules:

- Entries in a configuration data set are free format; blanks, comments, and end-of-record are ignored.
- A configuration statement consists of a statement name followed by a required blank, and usually one or more positional arguments. Separate each argument by one or more blanks or end-of-records.
- Lowercase letters are translated to uppercase letters before the statements are executed, except for those parameters that support mixed case entries.
- Static system symbols can be used in profile statements.

- Any IP address reference can be either an IPv4 format or IPv6 format IP address when the stack is running in IPv6-enabled mode.
- Each character must be a non-blank printable character.
- All characters must be entered in code page IBM-1047. The following are considered printable characters:

Table 30. Printable characters

Character	EBCDIC	Description
a-z	81-89, 91-99, A2-A9	Lowercase alphabetic
A-Z	C1-C9, D1-D9, E2-E9	Uppercase alphabetic
0-9	F0-F9	Numeric
¢	4A	Cent symbol
.	4B	Period
<	4C	Less than
(4D	Left parenthesis
+	4E	Plus
	4F	Vertical bar

*	5C	Asterisk
;	5E	Semicolon
,	6B	Comma
=	7E	Equal

Telnet parameter statements in the Telnet profile

Table 32 on page 496 provides a list of Telnet parameter statements and the location of more information.

The letter Y (with note references in parentheses) in a column indicates that the parameter can be coded in the indicated block. For example, CODEPAGE can be coded in TELNETGLOBALS, TELNETPARMS, or PARMSGROUP (affecting all connections on all ports, all connections on one port, or a subset of connections on one port, respectively).

<i>Table 32. Telnet parameter statements</i>				
Statement	TELNET GLOBALS	TELNET PARMS	PARMS GROUP	See
BINARYLINEMODE NOBINARYLINEMODE	Y	Y	Y See note 1.	“BINARYLINEMODE statement” on page 500

TKOSPECLU TKOSPECLURECON NOTKO	Y	Y	Y	“TKOSPECLU, TKOSPECLURECON, and NOTKO statements” on page 527
TN3270E NOTN3270E	Y	Y	Y See note 3.	“TN3270E statement” on page 528
TNSACONFIG	Y			“TNSACONFIG statement” on page 529
UNLOCKKEYBOARD	Y	Y	Y	“UNLOCKKEYBOARD statement” on page 531
XCFGROUP	Y			“XCFGROUP statement” on page 531

Note:

1. Changing or setting the function at LU assignment time using the LUMAP-PMAP statement might not provide the expected results. Use PARMSMAP for consistent results.
2. The statement definition is used before the user ID Client Identifier is determined and before LU assignment is performed. To use the statement in PARMSGROUP, the group must be mapped using PARMSMAP to any Client Identifier other than user ID or user group.
3. The function is negotiated with the client before LU assignment; therefore, LUMAP PMAP has no affect on these statements.

Rules for Telnet parameter statements

Observe the following rules for parameter statements:

- The value of parameter statements used by a connection is determined by the parameter hierarchy. All parameter values are initially set to Telnet default values and can then be modified using the TELNETGLOBALS block, TELNETPARMS block, or PARMSGROUP object. TELNETGLOBALS parameters affect all connections on all ports, TELNETPARMS parameters affect all connections on a single port, and PARMSGROUP parameters affect a subset of connections within a single port.
- If no statements are entered between TELNETPARMS and ENDTELNETPARMS, Telnet uses the default values for each of the TELNETPARMS statements.

Specific rules apply to security statements.

The CONNTYPE parameter statement is valid on a port with the value of TTLSPORT specified but not on a basic port.

BINARYLINEMODE statement

The BINARYLINEMODE parameter statement is used to prohibit translation of characters between EBCDIC and ASCII during linemode sessions. If NOBINARYLINEMODE is specified, standard linemode translation is implemented.

Syntax

Parameters

This statement has no parameters.

Telnet is initialized with the value NOBINARYLINEMODE.

BINARYLINEMODE and NOBINARYLINEMODE can be coded in TELNETGLOBALS, TELNETPARMS, or PARMSGROUP. See [“Rules for Telnet parameter statements” on page 499](#) for more information about the hierarchy of parameter values.

CHECKCLIENTCONN statement

Use the CHECKCLIENTCONN parameter statement to trigger the checking of the connectivity of all pre-existing connections associated with the client identifier of the new connection being established. The new connection is delayed early during connection negotiation until either all existing connections have responded or the specified wait time has elapsed. The number of existing connections checked can be limited with the *maxconns* parameter.

Guideline: No specific order is used when a limited number of connections are checked.

Syntax

Parameters

maxconns

The maximum number of connections checked for a single client identifier. The connections are not checked in any particular order. The range is 1 - 99999999. The default value for *maxconns* is 50.

Tip: This parameter can be important if you are using a proxy server. A proxy server causes all client connections to appear as if they are coming from the same client IP address. If you have a large number of connections coming in through a proxy server, Telnet sends timemarks out to each existing connection every time a new connection is established. The proxy server can be managed in either of the follow ways:

- Use the Parmsgroup/Parmsmap statements to specify the NoCheckClientConn option for the proxy server.
- Specify a small *maxconns* value to keep the number of connections checked for the proxy server low.

Telnet is initialized with the value NOCHECKCLIENTCONN.

The CHECKCLIENTCONN and NOCHECKCLIENTCONN statements can be coded in the TELNETGLOBALS, TELNETPARMS, or PARMSGROUP statement block. See [“Rules for Telnet parameter statements” on page 499](#) for more information about the hierarchy of parameter values.

sec

Number of seconds Telnet waits before checking whether a response was received from the client connections. Valid values are in the range 1 - 99 999 999.

CODEPAGE statement

Use the CODEPAGE parameter statement to specify ASCII-EBCDIC translation tables for linemode connections.

Telnet is initialized to use the ISO859-1 code page for ASCII and the IBM-1047 code page for EBCDIC.

CODEPAGE can be coded in TELNETGLOBALS, TELNETPARMS, or PARMSGROUP. See [“Rules for Telnet parameter statements” on page 499](#) for more information about the hierarchy of parameter values. If there is an error in the syntax, a default code page of ISO8859-1 is used for ASCII and the language environment code page taken from locale information is used as the EBCDIC code page. If the EBCDIC code page is in error, a default code page of IBM-1047 is used for EBCDIC.

If TNSTD is specified as either parameter, TNSTD is used for both. The Telnet table is based on the ISO08859-1/IBM-1047 translation tables with the following exceptions:

EBCDIC		ASCII	
x'0D25'	----->	x'0D0085'	using ISO8859-1/IBM-1047
x'0D25'	----->	x'0D0A'	using internal tables
x'15'	<----	x'0A'	using ISO8859-1/IBM-1047
x'25'	<----	x'0A'	using internal tables

Syntax

Parameters

ascii

The ASCII code page name. If TNSTD is specified, the TELNET-created translation table is used.

ebcdic

The EBCDIC code page name. If TNSTD is specified, the TELNET-created translation table is used.

CONNTYPE statement

Use the CONNTYPE parameter statement select different connection types.

CONNTYPE can be coded in TELNETPARMS or PARMSGROUP. See [“Rules for Telnet parameter statements” on page 499](#) for parameter statements for more information about the hierarchy of parameter values.

CONNTYPE is valid only with a secure port. See [“Rules for Telnet parameter statements” on page 499](#) for details.

Syntax

Parameters

SECURE

Indicates that the traditional SSL handshake is used to start the SSL connection. If the client does not start the handshake within the time specified in AT-TLS policy, an attempt is made to do a negotiated SSL handshake. If the client rejects the negotiated attempt, the connection is closed.

Telnet is initialized for secure ports TTLSPORT with CONNTYPE SECURE and for basic ports with CONNTYPE BASIC.

NEGTSECURE

Indicates that a TN3270 negotiation with the client determines if the client is willing to enter into a secure connection. If the client agrees, SSL protocols are used for all subsequent communication. If the client does not agree, the connection is closed.

BASIC

Indicates that a basic (non-SSL) connection is used.

ANY

Indicates that the client can connect as secure or basic. Telnet first tries a standard SSL handshake. If the handshake times out, negotiated SSL (see CONNTYPE NEGOTSECURE) is attempted.

- If the client is willing to enter into a secure connection, SSL protocols are used for all subsequent communication.
- If the client is not willing to enter into a secure connection, a basic connection is used.

NONE

Indicates that any client connection request is rejected.

DBCSTRACE statement

Use the DBCSTRACE parameter statement to activate additional, detailed tracing within the DBCS load module. The trace records are written to the SYSPRINT and TNDBCSE file. If NODBCSTRACE is specified, detailed trace records are not written.

Syntax

Parameters

This statement has no parameters.

Telnet is initialized with the value NODBCSTRACE. DBCSTRACE and NODBCSTRACE can be coded in TELNETPARMS or PARMSGROUP. See [“Rules for Telnet parameter statements” on page 499](#) for more information about the hierarchy of parameter values.

DBCSTRANSFORM statement

Use the DBCSTRANSFORM parameter statement to configure Telnet linemode to support 3270 SBCS or DBCS ASCII-EBCDIC transformations. The DBCSTRANSFORM statement specifies that Telnet should load the 3270 DBCS transform module, TNDBCSTM, at initialization. If the NODBCSTRANSFORM statement is specified, standard linemode translation is performed.

Telnet is initialized with the value NODBCSTRANSFORM. DBCSTRANSFORM and NODBCSTRANSFORM can be coded in TELNETPARMS or PARMSGROUP. See [“Rules for Telnet parameter statements” on page 499](#) for more information about the hierarchy of parameter values.

The TNDBCSTM module must be in a data set in the system search list. You can find the module in the installation data set, SEZALOAD. If you are using the 3270 DBCS transform mode, the TCP/IP address space might require additional virtual storage. The TNDBCSCN, TNDBCSSL, and TNDBCSE DD statements must be provided in the started procedure's JCL when DBCSTRANSFORM is specified. See the [linemode operation information in z/OS Communications Server: IP Configuration Guide](#) for details about their usage.

Transform is supported only on a single port. To use transform on a different port, the port using transform must be stopped using VARY TCP,IP,,T,STOP. Then an OBEYFILE command can be used to process a new Telnet profile, which defines transform support on another port.

If DBCSTRANSFORM is coded in multiple parameter blocks, the last port identified as DBCSTRANSFORM is the DBCSTRANSFORM port. The maximum number of transform connections is 250.

Syntax

Parameters

This statement has no parameters.

DEBUG statement

Use the DEBUG parameter statement to provide different levels of debug information for Telnet problems or tracking. Without this statement, only certain connection drop reasons are reported to the operator console.

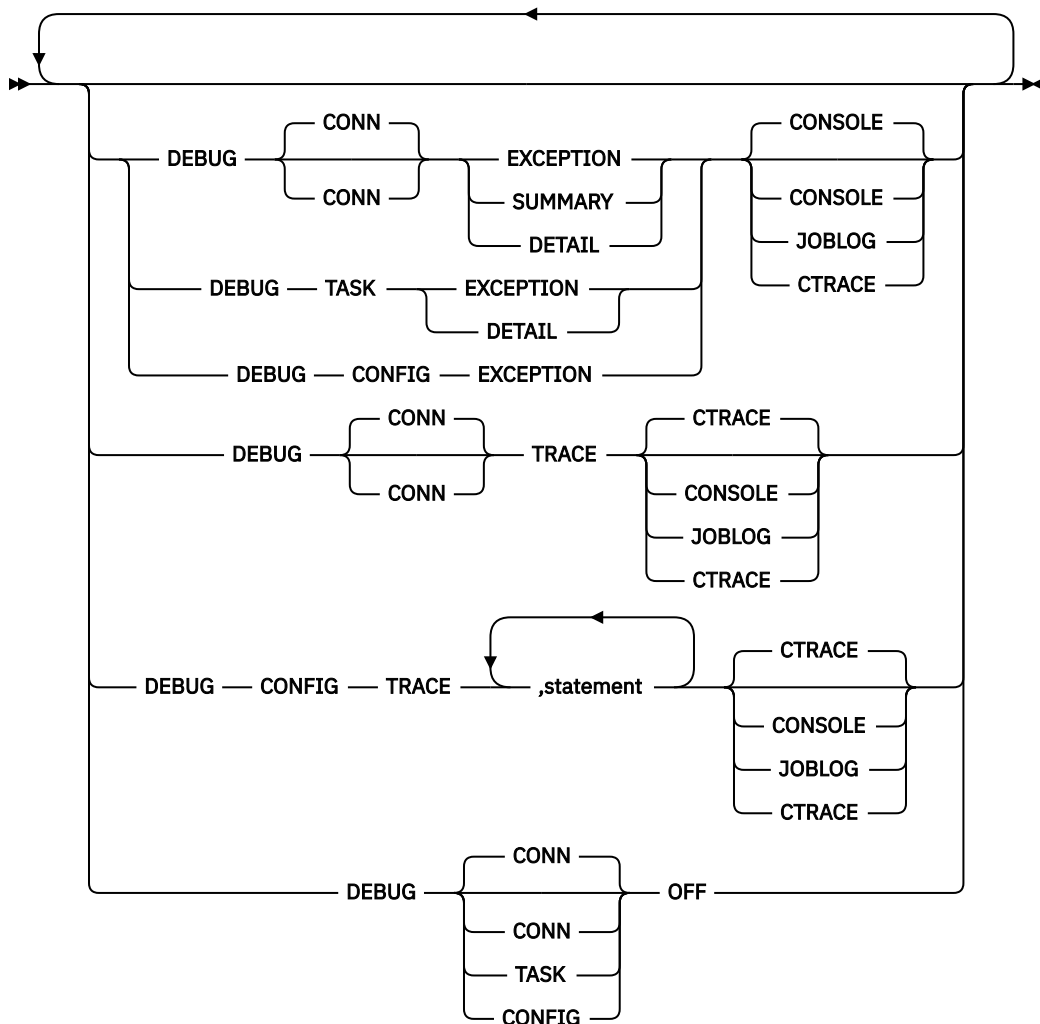

Telnet is initialized with DEBUG CONN EXCEPTION, DEBUG TASK EXCEPTION, and DEBUG CONFIG EXCEPTION settings.

You can code `DEBUG CONN` in `TELNETGLOBALS`, `TELNETPARMS`, or `PARMSGROUP`. See “Rules for Telnet parameter statements” on page 499 for more information about the hierarchy of parameter values. You can code `DEBUG CONFIG` and `DEBUG TASK` only in `TELNETGLOBALS`.

`DEBUG CONN`, `DEBUG TASK`, and `DEBUG CONFIG` can each be specified once in `TelenetGlobals` without generating a duplicate statement exception. The parameters `EXCEPTION`, `SUMMARY`, `DEBUG`, and `TRACE` are mutually exclusive on each of the three types of debug statements.

Use the `V TCPIP,,T,DEBUG,OFF` command to turn off all active debug reporting. This command also turns off the reporting of connection drops that were caused by timeouts or errors.

Syntax

Parameters

CONN

Specify `CONN` to issue debug messages for connections. `CONN` is the default.

TASK

Specify `TASK` to issue debug messages for Telnet tasks.

CONFIG

Specify `CONFIG` to issue debug messages for Telnet configuration statements. A `CONFIG` debug message (`EZZ6035I`) is issued showing the statements and parameters read by Telnet. Another `EZZ6035I` message is issued showing the structure of the statement as it is passed to Telnet database processing.

When OFF is specified, no debug messages are issued.

When EXCEPTION is specified, only exception debug messages are issued. Telnet is initialized with the value DEBUG CONN EXCEPTION.

When SUMMARY is specified, summary debug messages (EZZ6034I) are issued indicating major state changes. EXCEPTION debug messages are also issued when SUMMARY is specified.

When DETAIL is specified, detail debug messages (EZZ6035I) are issued to show key events occurring. You should specify DETAIL when you are solving problems; otherwise, too many messages are generated. EXCEPTION and SUMMARY messages are also issued when DETAIL is specified.

When TRACE is specified, data to and from the client and to and from VTAM for one connection is displayed by debug message EZZ6035I. Detail and summary messages are also issued when TRACE is specified. When DEBUG CONFIG is specified, you can optionally specify statement names immediately after the TRACE parameter to indicate that only those statements should be displayed. You can specify a maximum of 20 statement names.

When `JOBLOG` is specified, the debug messages are routed to the joblog (routing code 11) instead of the console.

When CONSOLE is specified, the debug messages are routed to the master console (routing code 2) and to the teleprocessing console (routing code 8).

When CTRACE is specified, the debug messages are not issued and appear in the Component Trace only.

See the “SGA statement” on page 518 for information about this statement.

Use the `DROPASSOCPRINTER` parameter statement to control whether or not the associated printer is dropped when the terminal connection is dropped.

Telnet is initialized with the value NODROPASSOCPRINTER.

DROPASSOCPRINTER and NODROPASSOCPRINTER can be coded in TELNETGLOBALS, TELNETPARMS, or PARMSGROUP. See [“Rules for Telnet parameter statements” on page 499](#) for more information about the hierarchy of parameter values.

Diagram illustrating the relationship between `NODROPASSOCPRINTER` and `DROPASSOCPRINTER`. A horizontal line with arrows at both ends is shown. Below it, a bracket spans the entire width, with `NODROPASSOCPRINTER` written above the bracket and `DROPASSOCPRINTER` written below the bracket.

This statement has no parameters.

EXPRESSLOGON statement

Use the EXPRESSLOGON parameter statement to allow a user at a workstation, with a TELNET client and an X.509 certificate, to log on to an SNA application without entering a user ID or password. Instead, the TN3270E Telnet server uses a dynamically-generated PassTicket based on the user's client X.509 certificate to authenticate the user. If NOEXPRESSLOGON is specified, EXPRESSLOGON function is not available to the client.

Telnet is initialized with the value NOEXPRESSLOGON.

The EXPRESSLOGON and NOEXPRESSLOGON statements can be coded in the TELNETGLOBALS, TELNETPARMS, or PARMSGROUP statement blocks. See [“Rules for Telnet parameter statements”](#) on page 499 for more information about the hierarchy of parameter values.

Requirements:

- The client must support the new environment Telnet option as defined in RFC 1572.
- When you are configuring the TTLSPORT value, the AT-TLS policy must specify HandshakeRole ServerWithClientAuth, a certificate must be received from the client, and the certificate must have an associated user ID.

Guideline: The EXPRESSLOGON and EXPRESSLOGONMFA statements are mutually exclusive. If both are specified on the same TELNETGLOBALS, TELNETPARMS, or PARMSGROUP statement, the last one specified on that statement is accepted. This guideline also applies to NOEXPRESSLOGON and NOEXPRESSLOGONMFA.

Syntax

Parameters

This statement has no parameters.

EXPRESSLOGONMFA statement

Use the EXPRESSLOGONMFA statement to allow a user at a workstation, with a TELNET client and an X.509 certificate, to log on to an SNA application without entering a user ID or password. Instead, the TN3270E Telnet server uses a Multi-Factor Authentication (MFA) token to authenticate the user. You can optionally configure the TN3270E Telnet server to fall back to PassTicket authentication in certain cases where MFA authentication is unsuccessful. MFA tokens and PassTickets are both based on the user's client X.509 certificate. If the NOEXPRESSLOGONMFA statement is specified, the EXPRESSLOGONMFA function is not available to the client.

Telnet is initialized with the value NOEXPRESSLOGONMFA.

The EXPRESSLOGONMFA and NOEXPRESSLOGONMFA statements can be coded in the TELNETGLOBALS, TELNETPARMS, or PARMSGROUP statement blocks. See [“Rules for Telnet parameter statements”](#) on page 499 for more information about the hierarchy of parameter values.

Requirements:

- The client must support the new environment Telnet option as defined in RFC 1572.
- When you configure the TTLSPORT value, the AT-TLS policy must specify the HandshakeRole ServerWithClientAuth statement, a certificate must be received from the client, and the certificate must have an associated user ID.

Guideline: The EXPRESSLOGONMFA and EXPRESSLOGON statements are mutually exclusive. If both are specified on the same TELNETGLOBALS, TELNETPARMS, or PARMSGROUP statement, the last one specified on that statement is accepted. This guideline also applies to NOEXPRESSLOGONMFA and NOEXPRESSLOGON.

Syntax

Parameters

NOFALLBACK

If MFA is active, but unavailable or if the MFA user is not provisioned with the same certificate in RACF and MFA, the Express Logon attempt will fail immediately. When EXPRESSLOGONMFA is specified it is initialized with this value.

FALLBACK

If MFA is active, but unavailable, the TN3270E server will fall back to using the same PassTicket authentication that is done by using the EXPRESSLOGON statement. If the MFA user is not provisioned with the same certificate in RACF and MFA, there is no fall back to use PassTicket authentication.

FORMAT statement

Use the FORMAT parameter statement to select the print format for display messages that are affected by longer IPv6 addresses.

Restriction: The FORMAT statement can be coded only in the TELNETGLOBALS statement block.

Syntax

Parameters

SHORT

The affected displays are presented in the existing one-line format. Telnet is initialized with a one-line format (FORMAT SHORT) in an IPv4 environment. A value of FORMAT SHORT cannot be coded in an IPv6 environment. All affected displays in an IPv6 environment use the new-wrapped line format.

LONG

The affected displays are presented in a new format that accommodate IPv6 addresses. Even if the Client Identifier is short enough for the existing one-line format, the new two-line format is used. This parameter can be used as a migration tool to see the new two-line display formats without specifying an IPv6 environment. Telnet is initialized with a two-line format (FORMAT LONG) in an IPv6 environment or whenever an IPv6 address is specified in the profile.

FULLDATATRACE statement

Use the FULLDATATRACE parameter statement to specify that all data to and from the client and all data to and from VTAM is completely traced when the CTRACE, TELNET OPTION, is chosen. If NOFULLDATATRACE is specified, the first 64 bytes of data are traced.

Telnet is initialized with the value NOFULLDATATRACE.

The FULLDATATRACE and NOFULLDATATRACE statements can be coded in the TELNETGLOBALS, TELNETPARMS, or PARMSGROUP statement blocks. See [“Rules for Telnet parameter statements”](#) on page 499 for more information about the hierarchy of parameter values.

Syntax

Parameters

This statement has no parameters.

INACTIVE statement

Use the INACTIVE parameter statement to define the terminal SNA session inactivity timeout. A connection that has no client-VTAM session activity for the specified time is dropped.

Telnet is initialized with a INACTIVE value of 0.

The INACTIVE statement can be coded in TELNETGLOBALS, TELNETPARMS, or PARMSGROUP statement blocks. See [“Rules for Telnet parameter statements”](#) on page 499 for more information about the hierarchy of parameter values.

Restriction: The INACTIVE statement applies to a KEEPOPEN connection only when an SNA session, with the VTAM application, is active.

Telnet uses one timer for the INACTIVE, PRTINACTIVE, and KEEPINACTIVE statements. See [z/OS Communications Server: IP Configuration Guide](#) for details.

Syntax

Parameters

0

An INACTIVE timeout value of 0 disables the inactivity timeout.

sec

Sets the inactivity timeout to the specified number of seconds. When a connection has had no session activity for the specified number of seconds, it is closed. This number must be an integer in the range 0 - 99 999 999.

INCLUDE statement

This statement causes profile statements from the named data set to be included at the point that the INCLUDE statement is encountered. In general, a profile statement must begin and end within

the same data set. For example, the statement beginning with BSDROUTINGPARMS and ending with ENDBSDROUTINGPARMS must be contained within the same data set. There are two exceptions to this requirement:

- INCLUDE statements can be used within the BEGINVTAM - ENDVTAM block of statements.
- INCLUDE statements can be used within a list of LUNAMES.

Syntax

➤ INCLUDE — *data_set_name* ➤

Parameters

data_set_name

A fully qualified data set name that identifies a sequential file. The sequential file can be a sequential data set or a PDS with the member name. It cannot be a z/OS UNIX file.

KEEPINACTIVE statement

Use the KEEPINACTIVE parameter statement to define the session setup inactivity timeout. A KEEPOPEN connection with no active SNA session that has no client-VTAM activity for the specified time is dropped.

Telnet is initialized with a KEEPINACTIVE value of 0.

The KEEPINACTIVE statement can be coded in the TELNETGLOBALS, TELNETPARMS, or PARMSGROUP statement blocks. See [“Rules for Telnet parameter statements” on page 499](#) for more information about the hierarchy of parameter values.

Restriction: The KEEPINACTIVE statement applies to a KEEPOPEN connection only when the connection does not have an active SNA session.

Telnet uses one timer for the INACTIVE, PRTINACTIVE, and KEEPINACTIVE statements. See [z/OS Communications Server: IP Configuration Guide](#) for details.

Syntax

➤ ——— ➤
| KEEPINACTIVE 0 |
| KEEPINACTIVE — *sec* |
| ——— |

Parameters

0

A KEEPINACTIVE timeout of 0 disables the inactivity timeout.

sec

Sets the inactivity timeout to the specified number of seconds. When a KEEPOPEN connection has had no session for the specified number of seconds, it is closed. This number must be an integer in the range 0 - 99 999 999.

KEEPLU statement

Use the KEEPLU parameter statement to reserve the LU for the Client Identifier when the LU is unassigned from the connection. The first reconnection request from the same Client Identifier mimics an end user requesting a specific connection with the kept LU name.

Telnet is initialized with a KEEPLU value of 0.

The KEEPLU statement can be coded in the TELNETGLOBALS, TELNETPARMS, or PARMSGROUP statement blocks. See [“Rules for Telnet parameter statements” on page 499](#) for more information about the hierarchy of parameter values.

Restriction: The KeepLU function cannot be performed for specific connection requests or associated printer requests.

If both KEEPLU and SEQUENTIALLU statements are active, the KEEPLU value is used.

Syntax

Parameters

0

A KEEPLU timeout of 0 disables the KEEPLU function.

sec

Sets the KEEPLU timeout to the specified number of seconds. When the LU has remained unassigned for the specified number of seconds, it becomes generally available. This number must be an integer in the range 0 - 99 999 999.

LIMITQ statement

Use the LIMITQ parameter statement to indicate that Telnet should not queue up data for later delivery if data is received from an emulator when Telnet does not have direction to send on the session.

Telnet is initialized with a value of NOLIMITQ.

The LIMITQ and NOLIMITQ statements can be coded in TELNETGLOBALS statement block only. See [“Rules for Telnet parameter statements” on page 499](#) for more information about the hierarchy of parameter values.

Syntax

Parameters

This statement has no parameters.

LUSESSIONPEND statement

Use the LUSESSIONPEND parameter statement to enable Telnet to redrive the DEFAULTAPPL, USS, or Solicitor screen after LOGOFF of the current session. If the NOLUSESSIONPEND value is specified, the Telnet connection is dropped after session LOGOFF.

Telnet is initialized with a value of NOLUSESSIONPEND.

The LUSESSIONPEND and NOLUSESSIONPEND statements can be coded in TELNETGLOBALS, TELNETPARMS, and PARMSGROUP statement blocks. See [“Rules for Telnet parameter statements” on page 499](#) for more information about the hierarchy of parameter values.

Syntax

Parameters

This statement has no parameters.

MAXRECEIVE statement

Use the MAXRECEIVE parameter statement to limit the number of bytes received from a client without an End of Record (EOR) being received. If the amount of data received exceeds the limit, the connection is dropped. This parameter protects against a client in a send-data loop.

Telnet is initialized with a MAXRECEIVE value of 65 536.

The MAXRECEIVE statement can be coded in the TELNETGLOBALS, TELNETPARMS, or PARMSGROUP statement blocks. See [“Rules for Telnet parameter statements” on page 499](#) for more information about the hierarchy of parameter values. A low value (less than 10 000) can cause unintended connection drops.

Syntax

Parameters

0

A MAXRECEIVE value of 0 disables the limit check function.

num_bytes

Sets the number of data bytes permitted to be received without receiving an EOR. This number must be an integer in the range 0 - 99 999 999.

MAXREQSESS statement

Use the MAXREQSESS parameter statement to limit the number of session requests received by Telnet in a 10-second period. For this parameter, a BIND received by Telnet defines a session request. If the number of BINDs received in a 10-second period exceeds the limit, the connection is dropped and an error is reported.

Telnet is initialized with a MAXREQSESS value of 20.

The MAXREQSESS statement can be coded in the TELNETGLOBALS, TELNETPARMS, or PARMSGROUP statement blocks. See [“Rules for Telnet parameter statements” on page 499](#) for more information about the hierarchy of parameter values.

Syntax

Parameters

0

A MAXREQSESS value of 0 disables the limit check function.

num_req

Sets the number of session requests permitted in a 10-second period. This number must be an integer in the range 0 - 99,999,999.

MAXRUCHAIN statement

Use the MAXRUCHAIN parameter statement to limit the number of chained RUs received from an application without an end of chain (EC) being received. If the number of RUs received exceeds the limit, the session, and conditionally the connection, is dropped. This parameter protects against a host application from sending too much chained data.

Telnet is initialized with a MAXRUCHAIN value of 0.

The MAXRUCHAIN statement can be coded in the TELNETGLOBALS, TELNETPARMS, or PARMSGROUP statement blocks. See [“Rules for Telnet parameter statements” on page 499](#) for more information about the hierarchy of parameter values.

Syntax

Parameters

0

A MAXRUCHAIN value of 0 disables the function.

num_RUs

Sets the number of chained RUs permitted to be received before the RU chain is ended. This number must be an integer in the range 0 - 99,999,999.

MAXTCPSENDQ statement

Use the MAXTCPSENDQ parameter statement to limit the number of bytes that are queued to be sent to a Telnet client. If the queue size exceeds the limit, the connection is dropped. This parameter prevents large amounts of storage from being held for data that is destined for an unresponsive Telnet client.

Telnet is initialized with a MAXTCPSENDQ value of 0.

The MAXTCPSENDQ statement can be coded in the TELNETGLOBALS, TELNETPARMS, or PARMSGROUP statement block. See [“Rules for Telnet parameter statements” on page 499](#) for more information about the hierarchy of parameter values.

Syntax

Parameters

0

A MAXTCPSSENDQ value of 0 disables the limit check function.

num_bytes

Sets the number of bytes that can be queued to a Telnet client at one time. This number must be an integer in the range 0 - 99999999. A low value can cause unintended connection drops.

MAXVTAMSENDQ statement

Use the MAXVTAMSENDQ parameter statement to limit the number of data segments (RPLs) queued to be sent to VTAM. If the queue size exceeds the limit, the connection is dropped. This parameter protects against using large amounts of storage to contain data destined for a host VTAM application that is not receiving data.

Telnet is initialized with a MAXVTAMSENDQ value of 50.

The MAXVTAMSENDQ statement can be coded in the TELNETGLOBALS, TELNETPARMS, or PARMSGROUP statement block. See [“Rules for Telnet parameter statements” on page 499](#) for more information about the hierarchy of parameter values.

Syntax

Parameters

0

A MAXVTAMSENDQ value of 0 disables the limit check function.

num_rpls

Sets the number of RPLs permitted to be queued to VTAM at one time. This number must be an integer in the range 0 - 99 999 999. A value less than 10 can cause unintended connection drops.

MSG07 statement

Use the MSG07 parameter statement to activate logon error message processing. Specifying this statement provides information to the client when a session attempt to the target application fails. If NOMSG07 is specified, the connection is dropped if a session initiation error occurs.

Telnet is initialized with a value of NOMSG07.

The MSG07 and NOMSG07 statements can be coded in TELNETGLOBALS, TELNETPARMS, and PARMSGROUP statement blocks. See [“Rules for Telnet parameter statements” on page 499](#) for more information about the hierarchy of parameter values.

Syntax

Parameters

This statement has no parameters.

NACUSERID statement

Use the NACUSERID statement to associate one or more Telnet ports with a user ID defined to the security server. This provides Network Access Control checking with a user ID other than Telnet's address space user ID. If NONACUSERID is specified, Network Access Control uses Telnet's address space user ID.

Telnet is initialized with a value of NONACUSERID.

The NACUSERID and NONACUSERID statements can be coded in the TELNETGLOBALS or TELNETPARMS statement blocks.

Syntax

Parameters

NAC_name

Any valid user ID up to 8 characters in length.

OLDSOLICITOR statement

Use the OLDSOLICITOR parameter statement to place the initial cursor on the solicitor panel after the following prompt:

```
Enter Your Userid:
```

If NOOLDSOLICITOR is specified, the cursor is placed after the following prompt:

```
Application:
```

Telnet is initialized with a value of NOOLDSOLICITOR.

The OLDSOLICITOR and NOOLDSOLICITOR statements can be coded in TELNETGLOBALS, TELNETPARMS, or PARMSGROUP statement block. See [“Rules for Telnet parameter statements” on page 499](#) for more information about the hierarchy of parameter values.

Syntax

Parameters

This statement has no parameters.

PASSWORDPHRASE statement

Use the PASSWORDPHRASE statement to provide additional entry space on the solicitor screen for end users to enter either a password or a password phrase. When a new password or password phrase is entered, the user is asked to verify the new value.

Rule: The PASSWORDPHRASE statement is only effective if RESTRICTAPPL is coded. This operand affects only the solicitor screen and does not affect the password phrase capability of applications accessed using Telnet.

If NOPASSWORDPHRASE is specified, the solicitor screen continues to provide space for only a password.

If DISABLEPASSWORDPHRASE is specified, the solicitor screen provides support for only a password. The password is sent in the same format as it was in before z/OS V1R13.

Tip: The layout of the solicitor screen is changed to accommodate the larger password phrase. If you use a screen scraper, you must account for this change. If your client does not use 3270 data stream commands, code DISABLEPASSWORDPHRASE until the client is updated.

TELNET is initialized with the value NOPASSWORDPHRASE.

The DISABLEPASSWORDPHRASE, PASSWORDPHRASE, and NOPASSWORDPHRASE statements can be coded in the TELNETGLOBALS, TELNETPARMS, or PARMSGROUP statement block. See [“Rules for Telnet parameter statements”](#) on page 499 for more information about the hierarchy of parameter values.

Syntax

Parameters

This statement has no parameters.

PORT and TTLSPORT statements

Use the PORT parameter statement to define the port that Telnet listens on for non-secure (basic) connection requests.

Use the TTLSPORT parameter statement to define the port that Telnet listens on for secure connection requests from a client that uses the TCP/IP AT-TLS interface. If you use the TTLSPORT statement, you must define security parameters in AT-TLS policy.

Telnet is initialized with a value of PORT 23.

Restrictions:

- You can code the PORT or TTLSPORT statements only in the TELNETPARMS statement block.
- If you code a qualifier value (*qual*), it must match the qualifier used in the PORT statement in the BEGINVTAM block.

Specifying TTPSPORT is the same as specifying CONNTYPE SECURE; PORT is the same as specifying CONNTYPE BASIC. See [“CONNTYPE statement” on page 502](#) for more information.

In the BEGINVTAM block, the PORT statement serves a different purpose. It links the BEGINVTAM block to the TELNETPARMS block with the same port number.

Syntax

Parameters

num

A specified port number.

,qual

Qualifies the port address (PORT) with a destination IP address or with a specific link name.

PROFILEINACTIVE statement

Use the PROFILEINACTIVE parameter statement to define the timeout for connections associated with a non-current profile that do not have a SNA session. A connection that does not have a SNA session for the specified time and that is associated with a non-current profile is dropped. Telnet uses one timer for the INACTIVE, PROFILEINACTIVE, PRTINACTIVE, and KEEPINACTIVE statements. See [z/OS Communications Server: IP Configuration Guide](#) for more information. You can code the PROFILEINACTIVE statement in the TELNETGLOBALS, TELNETPARMS, or PARMSGROUP statement blocks. See [“Rules for Telnet parameter statements” on page 499](#) for more information about the hierarchy of parameter values.

Telnet is initialized with a PROFILEINACTIVE timeout value of 1800 seconds.

Syntax

Parameters

1800

This PROFILEINACTIVE timeout value sets the inactivity value to 1800 seconds.

sec

Sets the inactivity timeout to the specified number of seconds. This number must be an integer in the range 0-99 999 999. A PROFILEINACTIVE timeout value of 0 disables the function.

PRTINACTIVE statement

Use the PRTINACTIVE parameter statement to define the printer inactivity timeout. A printer connection with no client-VTAM activity for the specified time is dropped.

Telnet is initialized with a PRTINACTIVE value of 0.

The PRTINACTIVE statement can be coded in the TELNETGLOBALS, TELNETPARMS, or PARMSGROUP statement blocks. See [“Rules for Telnet parameter statements” on page 499](#) for more information about the hierarchy of parameter values.

Telnet uses one timer for INACTIVE, PRTINACTIVE, and KEEPINACTIVE. See [z/OS Communications Server: IP Configuration Guide](#) for more details.

Syntax

Parameters

0

A PRTINACTIVE timeout value of 0 disables inactivity timeout.

sec

Sets the inactivity timeout to a specified number of seconds. When a printer connection has been inactive for the specified number of seconds, it is closed. The number must be an integer in the range 0 - 99 999 999.

REFRESHMSG10 statement

Use the REFRESHMSG10 parameter statement to specify the action to be taken when a clear key is entered from a USSMSG message. If the REFRESHMSG10 parameter statement is specified, Telnet toggles between clearing the screen and returning to the USSMSG10 panel. When the screen is cleared, the cursor is placed at location row one and column two.

If the NOREFRESHMSG10 parameter statement is specified, the screen is always cleared, and the cursor is placed at location row one and column one.

Telnet is initialized with the REFRESHMSG10 parameter statement.

The REFRESHMSG10 and NOREFRESHMSG10 parameter statements can be coded in the TELNETGLOBALS, TELNETPARMS and PARMSGROUP statement blocks.

Syntax

Parameters

This statement has no parameters.

SCANINTERVAL and TIMEMARK statements

Use the SCANINTERVAL parameter statement to define the interval at which Telnet checks connections for inbound TCP/IP activity. It is used in conjunction with the TIMEMARK parameter statement, which defines the elapsed time Telnet uses to determine whether a connection to the client is considered broken. During SCANINTERVAL processing, if the elapsed time since the last inbound activity is greater than the TIMEMARK value, the connection is considered possibly broken and a TIMEMARK request is sent

to the client. At the next interval, if neither a TIMEMARK request nor data is received, the connection is considered broken. Telnet drops the connection.

SCANINTERVAL and TIMEMARK can be coded in TELNETGLOBALS, TELNETPARMS, or PARMSGROUP. See [“Rules for Telnet parameter statements” on page 499](#) for more information about the hierarchy of parameter values.

If for any reason the TIMEMARK cannot be sent immediately on five consecutive tries and no data or TIMEMARK response is received, the connection is dropped. When TIMEMARK cannot be sent immediately, Telnet tries again at the next SCANINTERVAL time. If the SCANINTERVAL is greater than the TIMEMARK value, it is reset to the TIMEMARK value.

Syntax

Parameters

1800

Telnet is initialized with a SCANINTERVAL value of 1800 seconds.

sec1

Sets the SCANINTERVAL time to a specified number of seconds. This value is in the range 1 - 99,999,999. A value of 0 is not valid.

10,800

Telnet is initialized with a TIMEMARK value of 10,800 seconds.

sec2

Sets the TIMEMARK time to a specified number of seconds. This value is in the range 1 - 99,999,999. A value of 0 is not valid.

SEQUENTIALLU statement

Use the SEQUENTIALLU parameter statement allows sequential LU selection from the LU group. If NOSEQUENTIALLU is specified, the first LU available in the group is used.

Telnet is initialized with SEQUENTIALLU.

SEQUENTIALLU and NOSEQUENTIALLU can be coded in TELNETGLOBALS, TELNETPARMS, or PARMSGROUP. See [“Rules for Telnet parameter statements” on page 499](#) for more information about the hierarchy of parameter values.

Syntax

Parameters

This statement has no parameters.

SGA statement

Use the NOSGA (DISABLESGA) parameter statement to permit the transmission of GO AHEAD by Telnet. It is negotiated by both client and server. Using NoSGA increases the overhead for a full duplex terminal and a full duplex connection. If SGA is specified, transmission of GO AHEAD is suppressed.

Telnet is initialized with a value of SGA.

The SGA and NOSGA statements can be coded in the TELNETGLOBALS, TELNETPARMS, or PARMSGROUP statement block. See [“Rules for Telnet parameter statements” on page 499](#) for more information about the hierarchy of parameter values.

Syntax

Parameters

This statement has no parameters.

SHAREACB statement

Use the SHAREACB parameter statement to allow multiple Telnet LUs to share an ACB. Telnet server can use ECSA storage more efficiently by using this parameter. If NOSHAREACB is specified, ACB sharing does not occur.

Telnet is initialized with a value of NOSHAREACB.

Guideline: Use of the SHAREACB statement requires Telnet LUs to be defined with model APPL names in the VTAM configuration data set.

The SHAREACB and NOSHAREACB statements can be coded in the TELNETGLOBALS statement block only.

Syntax

Parameters

This statement has no parameters.

SIMCLIENTLU statement

Use the SIMCLIENTLU parameter statement to cause Telnet to send a standard LU name (EZBSIMLU) during negotiation to any TN3270E client requesting a Generic connection. Instead of assigning a Telnet LU, the LU assignment is deferred until after application selection, just like TN3270 clients. If NOSIMCLIENTLU is specified, normal device name negotiation occurs for TN3270E connections.

Telnet is initialized with a value of NOSIMCLIENTLU.

The SIMCLIENTLU and NOSIMCLIENTLU statements can be coded in the TELNETGLOBALS, TELNETPARMS, or PARMSGROUP statement blocks. See [“Rules for Telnet parameter statements” on page 499](#) for more information about the hierarchy of parameter values.

When the TN3270E client requests a connection with a specific LU, the selection of the LU is handled like normal TN3270E specific processing, regardless of the SIMCLIENTLU statement. Printer requests are not affected by the SIMCLIENTLU statement.

Syntax

Parameters

This statement has no parameters.

SINGLEATTN statement

Use the SINGLEATTN parameter statement to cause Telnet to check the data for a double ATTENTION key combination, x'6CFFEFF3', in the data stream sent from the client. If a double ATTENTION key combination is found, Telnet sends only a single ATTENTION. If NOSINGLEATTN is specified, the data is not checked.

Telnet is initialized with a value of NOSINGLEATTN.

The SINGLEATTN and NOSINGLEATTN statements can be coded in the TELNETGLOBALS, TELNETPARMS, or PARMSGROUP statement blocks. See [“Rules for Telnet parameter statements” on page 499](#) for more information about the hierarchy of parameter values.

Syntax

Parameters

This statement has no parameters.

SMFINIT and SMFTERM statements

Use the SMFINIT and SMFTERM parameter statements to configure Telnet to write SMF records. These statements control the invocation of Telnet SNA Session Initiation (or LOGON, subtype 20) and Telnet SNA Session Termination (or LOGOFF, subtype 21) SMF records.

Two different record formats are available:

- Format 118
- Format 119

The format 119 records are controlled by use of the TYPE119 operand on the SMFINIT and SMFTERM statements. The specification of the STD operand or a nonstandard subtype number on the SMFINIT and SMFTERM statements control the usage of the older format 118 record processing.

Telnet is initialized with the following values:

- SMFINIT 0
- SMFINIT NOTYPE119

- SMFTERM 0
- SMFTERM NOTYPE119

SMFINIT and SMFTERM can be coded in TELNETGLOBALS, TELNETPARMS, and PARMSGROUP. See [“Rules for Telnet parameter statements” on page 499](#) for more information about the hierarchy of parameter values.

TCP/IP SMF records are independent of the IP connection. They are created for Telnet LU/HOST application sessions.

Many products use standard SMF record subtypes. A standard subtype avoids potential double usage and makes it easier for other vendors to write SMF output processing programming and for Telnet administrators to be consistent across multiple machines.

Syntax

Parameters

STD

Specifies that format 118 SMF records should be written using standard subtypes for LOGON (20) or LOGOFF (21) records.

nn

Specifies the format 118 SMF record subtype for LOGON or LOGOFF records. Valid values are integers in the range 0 - 255. A value of 0 for SMFINIT and SMFTERM indicates that no SMF record is written for that function. The user can change the subtype value only for the format 118 records.

TYPE119

Specifies that format 119 SMF records should be written for Telnet SNA Session Initiation (subtype 20) or Telnet SNA Session Termination (subtype 21) records.

NOTYPE119

Specifies that format 119 SMF records should not be written.

SMFPROFILE statement

Use the SMFPROFILE parameter statement to configure Telnet to write SMF configuration records. The Telnet configuration records are written as type 119, subtype 24. For more information about the layout of the configuration records, see [z/OS Communications Server: IP Configuration Guide](#).

Telnet is initialized with a value of NOSMFPROFILE.

The SMFPROFILE and NOSMFPROFILE statements can be coded in only the TELNETGLOBALS statement block. See [“Rules for Telnet parameter statements” on page 499](#) for more information about the hierarchy of parameter values.

Syntax

Parameters

GROUPDETAIL | NOGROUPDETAIL

GROUPDETAIL includes all of the individual members of the Telnet group statements in the SMF records. NOGROUPDETAIL includes only the first 10 members of each group. GROUPDETAIL is the default. The following list shows Telnet group statements:

- ALLOWAPPL or RESTRICTAPPL
- DEFAULTLUS or SDEFAULTLUS
- DEFAULTLUSSPEC or SDEFAULTLUSSPEC
- DEFAULTPRT or SDEFAULTPRT
- DEFAULTPRTSPEC or SDEFAULTPRTSPEC
- DESTIPGROUP
- HNGROUP
- IPGROUP
- LINKGROUP
- LUGROUP or SLUGROUP
- PRTGROUP or SPRTGROUP
- USERGROUP

Tip: GROUPDETAIL can greatly increase the number of SMF records generated for each Telnet profile. Use only if each individual member of a group is needed in the records.

SNAEXT statement

Use the SNAEXT parameter statement to enable negotiation for contention resolution and SNA sense functions for TN3270E connections. If NOSNAEXT is specified, Telnet does not negotiate these SNA functional extensions.

Telnet is initialized with a value of SNAEXT.

The SNAEXT and NOSNAEXT statements can be coded in TELNETGLOBALS, TELNETPARMS, or PARMSGROUP statement block. See [“Rules for Telnet parameter statements” on page 499](#) for more information about the hierarchy of parameter values.

The NOSNAEXT statement is useful in the unlikely case there are a significant number of clients that cannot tolerate the negotiation of these functions. Most clients do not have a problem with the SNAEXT specification in Telnet, but, in the unlikely case that some do, specify and map NOSNAEXT to that set of clients.

Syntax

Parameters

This statement has no parameters.

TCPIPJOBNAME statement

Use the TCPIPJOBNAME parameter statement to give the Telnet port affinity to the specified TCPIP stack. If NOTCPIPJOBNAME is specified, the port is an undirected port and binds with all stacks that have the port available.

Telnet is initialized with a value of NOTCPIPJOBNAME.

Restriction: You cannot change the TCPIPJOBNAME statement in a subsequent Telnet OBEYFILE command; you must restart Telnet to change its stack affinity.

The TCPIPJOBNAME and NOTCPIPJOBNAME statements can be coded in the TELNETGLOBALS statement block only. See [“Rules for Telnet parameter statements” on page 499](#) for more information about the hierarchy of parameter values.

Syntax

Parameters

tcp_stack_name

The name of the TCPIP stack to which the Telnet port binds.

TELNETDEVICE statement

Use the `TELNETDEVICE` parameter statement to specify a logmode for a device type. This statement accepts two logmodes:

- TN3270 connections
- TN3270E connections

Syntax

Parameters

telnet_device_type

The type of Telnet device. See [Table 33 on page 524](#) for accepted device types.

tn3270_logmode

The logmode name used on TN3270 connections for the specified *telnet_device_type*.

tn3270e_logmode

The logmode name used on TN3270E connections for the specified *telnet_device_type*.

Device type and logmode table

<i>Table 33. Device type and logmode table</i>		
Telnet device type	TN3270 logmode entry	TN3270E logmode entry
IBM-3277	D4B32782	Not applicable
IBM-3278-2-E	NSX32702	SNX32702
IBM-3278-2	D4B32782	SNX32702
IBM-3278-3-E	NSX32702	SNX32703
IBM-3278-3	D4B32783	SNX32703
IBM-3278-4-E	NSX32702	SNX32704
IBM-3278-4	D4B32784	SNX32704
IBM-3278-5-E	NSX32702	SNX32705
IBM-3278-5	D4B32785	SNX32705
IBM-3279-2-E	NSX32702	SNX32702
IBM-3279-2	D4B32782	SNX32702
IBM-3279-3-E	NSX32702	SNX32703
IBM-3279-3	D4B32783	SNX32703
IBM-3279-4-E	NSX32702	SNX32704
IBM-3279-4	D4B32784	SNX32704
IBM-3279-5-E	NSX32702	SNX32705
IBM-3279-5	D4B32785	SNX32705
IBM-3287-1	Not applicable	D6328904
IBM-DYNAMIC	D4C32XX3	D4C32XX3
LINEMODE	INTERACT	Not applicable
TRANSFORM	D4B32782	Not applicable

Telnet is initialized to the logmode names listed in [Table 33 on page 524](#). All the named logmode entries are defined to VTAM in the default logmode table, *ISTINCLM*. The TN3270 logmodes are non-SNA, and the TN3270E logmodes are SNA. For more details, see [z/OS Communications Server: SNA Resource Definition Reference](#).

The *TELNETDEVICE* parameter statement can be coded in *TELNETGLOBALS*, *TELNETPARMS*, or *PARMSGROUP* statement blocks. See [“Rules for Telnet parameter statements” on page 499](#) for more information about the hierarchy of parameter values.

Telnet supports non-SNA (LU0) and SNA (LU2) terminal sessions. Telnet supports SNA character stream (SCS) (LU1) and 3270 data character stream (DCS) (LU3) printer sessions.

The specified logmode name can be an IBM-supplied logmode or user-created. If user-created, the BIND characteristics must be compatible with the LU type. TN3270 and TN3270E connections support either non-SNA or SNA BINDs.

The LOGMODE name NONE prevents Telnet from specifying a LOGMODE request with the REQSESS.

Telnet cannot verify that the logmode specified is valid at configuration time. Problems are detected at run time. For more information about logmodes, see [z/OS Communications Server: SNA Resource Definition Reference](#).

TESTMODE statement

An operator can use the TESTMODE statement to test the new statements for a port without applying them. All the processing and checking is done for an actual port update, but at the end of the process, instead of applying the new statements, all data structures for that port are released. TESTMODE applies only to the port that is defined in the TELNETPARMS section where it is coded and not to the entire profile. If this statement is not coded, the profile for the port becomes the current profile when it is processed.

TESTMODE can be coded only in the TELNETPARMS statement block.

With the TESTMODE statement coded in all of the TELNETPARMS blocks, a Telnet administrator can issue a VARY TCPIP,,OBEYFILE command for a profile data set and can determine whether there are any syntax or semantic errors without concern for applying a profile that is not valid. TESTMODE profiles can be processed as often as necessary.

The TESTMODE statement can be specified in the initial startup profile. However, the end result is that the port is not opened and clients cannot connect. It would be as if no profile statements existed for that port.

Syntax

Parameters

This statement has no parameters.

TIMEMARK statement

For a description of the TELNETPARMS TIMEMARK statement, see [“SCANINTERVAL and TIMEMARK statements” on page 517](#).

TKOGENLU, TKOGENLURECON, and NOTKO statements

Use the TKOGENLU and TKOGENLURECON statements to enable an existing Telnet connection and its emulator, the target, to be taken over by a new Telnet connection and its emulator, the taker, under certain circumstances. NOTKOGENLU blocks generic takeover attempts and NOTKO blocks any takeover attempt of the target connection.

Two types of takeover exist:

- Specific LU takeover
- Generic LU takeover

The way a target can be taken over is defined in the profile associated with the target connection. The target can be set up to allow either or both takeover methods. The taker determines which takeover method is tried. If the taker specifies an LU name, a specific LU takeover is attempted, and the target must allow either TKOSPECLU or TKOSPECLURECON. If the taker specifies no LU name, a generic LU takeover is being attempted, and the target must allow either TKOGENLU or TKOGENLURECON.

When the profile indicates that generic takeover is allowed, Telnet saves the LU name of the first connection for each unique client identifier for all connections that allow generic takeover. Use generic takeover when there is only one connection per client identifier.

When generic takeover is allowed and a new generic connection request arrives, Telnet checks to determine whether the new connection client identifier already is already associated with an LU name. If client identifier does, Telnet attempts to take over the connection associated with that LU name. Telnet LU lookup suspends the new connection request. After the new connection is suspended, a TIMEMARK is sent to the original connection that is using the requested LU name. After the specified period of time, Telnet checks whether or not there was a response to the TIMEMARK. If a response or any data is received by the original connection since the TIMEMARK was sent out, Telnet fails the new connection takeover attempt and then assigns the next available LU name to the new connection. If no response is received, the target connection is dropped and the new taker connection is established with the saved LU name. If TKOGENLU is in effect, the session is also dropped. If TKOGENLURECON is in effect, the session is transferred to the taker connection.

Restriction: If the NOTKOGENLU or NOTKO statement is specified, generic takeover of the target cannot be performed.

Telnet is initialized with a value of NOTKO.

The TKOGENLU, TKOGENLURECON, NOTKOGENLU and NOTKO statements can be coded in the TELNETGLOBALS, TELNETPARMS, or PARMSGROUP statement block. See [“Rules for Telnet parameter statements”](#) on page 499 for more information about the hierarchy of parameter values.

Generic LU takeover and specific LU takeover can coexist. TKOGENLU and TKOGENLURECON are mutually exclusive. TKOSPECLU and TKOSPECLURECON are mutually exclusive.

When the TKOGENLU or TKOGENLURECON statement is specified and one connection exists for a client, any additional connection request first tries takeover using the first connection LU name. After the takeover request fails, Telnet continues generic LU lookup. Therefore, all additional connection requests are delayed by the takeover time specified.

In some cases, the TKOGENLURECON session cannot be maintained. See [z/OS Communications Server: IP Configuration Guide](#), Advanced Application topics for details.

Syntax

Parameters

sec

Number of seconds Telnet waits before checking to determine whether a response was received from the original client. The range is 0 - 99 999 999. Zero is a special case value. If you code 0 in the sec field, Telnet always performs the takeover, whether the original session is active or not.

KEEPONTMRESET

If a reset is received from the target during takeover, the session is saved and transferred to the taker. If the KEEPONTMRESET parameter is not specified, or if the NOKEEPONTMRESET parameter is specified, the session is dropped if a reset is received from the target.

SAMEIPADDR

Ensures that the taker has the same IP address as the target. If the SAMEIPADDR parameter is not specified, or if the NOSAMEIPADDR parameter is specified, a taker with a different IP address can take over the target. The changed IP address is not forwarded to the application, which could cause possible reporting errors.

SAMECONNTYPE

Ensures that the taker has the same basic or secure connection type as the target. If the SAMECONNTYPE parameter is not specified, or if the NOSAMECONNTYPE parameter is specified, a taker with a secure connection can take over a target with a basic connection. The original connection type is forwarded to the application as part of the CINIT CV64 information. The changed connection type from basic to secure is not forwarded to the application, which could cause possible reporting errors.

TKOSPECLU, TKOSPECLURECON, and NOTKO statements

Use the TKOSPECLU and TKOSPECLURECON statements to enable an existing Telnet connection and its emulator, the target, to be taken over by a new Telnet connection and its emulator, the taker, under certain circumstances. NOTKOSPECLU blocks specific takeover attempts and NOTKO blocks any takeover attempt of the target connection.

The following types of takeover exist:

- Specific LU takeover
- Generic LU takeover

The way a target can be taken over is defined in the profile associated with the target connection. The target can be set up to allow either or both takeover methods. The taker determines which takeover method is tried. If the taker specifies an LU name, a specific LU takeover is attempted, and the target must allow either TKOSPECLU or TKOSPECLURECON. If the taker does not specify an LU name, a generic LU takeover is being attempted, and the target must allow either TKOGENLU or TKOGENLURECON.

When specific LU takeover is allowed, Telnet LU lookup suspends a new connection request that specifies an already active LU name. After the new connection is suspended, a TIMEMARK is sent to the original connection that is using the requested LU name. After the specified period of time, Telnet checks whether there was a response to the TIMEMARK. If a response or any data is received by the original connection since the TIMEMARK was sent out, Telnet fails the new connection takeover attempt by indicating the LU name is already in use. If no response is received, the target connection is dropped and the new taker connection is established with the specified LU name. If TKOSPECLU is in effect, the session is also dropped. If TKOSPECLURECON is in effect, the session is transferred to the taker connection.

Restriction: If the NOTKO statement or the NOTKOSPECLU statement is specified, specific takeover of the target cannot be performed.

Telnet is initialized with a value of NOTKO.

The TKOSPECLU, TKOSPECLURECON, NOTKOSPECLU and NOTKO statements can be coded in the TELNETGLOBALS, TELNETPARMS, or PARMSGROUP statement block. See [“Rules for Telnet parameter statements” on page 499](#) for more information about the hierarchy of parameter values.

Generic LU takeover and specific LU takeover can coexist. The TKOGENLU and TKOGENLURECON statements are mutually exclusive. The TKOSPECLU and TKOSPECLURECON statements are mutually exclusive.

Requirements:

- To take over the session using the TKOSPECLU or TKOSPECLURECON statement, the new connection must specify the LU name. If administrators want to use this function for a more general purpose, code the @@LUNAME character substitution in the MSG10 screen so end users know their LU name if they need to issue a takeover. Also, some clients display the LU name assigned by Telnet.
- You must have a specific LU pool for a specific LU connection request. If you are switching from generic LU connection requests to specific LU connection requests and are using the DEFAULTLUS pool, a DEFAULTLUSSPEC pool must be defined.

In some cases, the TKOSPECLURECON session cannot be maintained. See [z/OS Communications Server: IP Configuration Guide](#), Advanced Application topics for details

Syntax

Parameters

sec

Number of seconds Telnet waits before checking whether a response was received from the original client. Valid values are in the range 0 - 99 999 999. The value 0 is a special case value. If you code 0 in the sec field, Telnet always performs the takeover, whether the original session is active or not.

KEEPONTMRESET

If a reset is received from the target during takeover, the session is saved and transferred to the taker. Without KEEPONTMRESET or if NOKEEPONTMRESET is specified, the session is dropped if a reset is received from the target.

SAMEIPADDR

Ensures that the taker has the same IP address as the target. Without SAMEIPADDR or if NOSAMEIPADDR is specified, a taker with a different IP address can take over the target. The changed IP address is not forwarded to the application, which could cause possible reporting errors.

SAMECONNTYPE

Ensures that the taker has the same basic or secure connection type as the target. If the SAMECONNTYPE parameter is not specified, or if the NOSAMECONNTYPE parameter is specified, a taker with a secure connection can take over a target with a basic connection. The original connection type is forwarded to the application as part of the CINIT CV64 information. The changed connection type from basic to secure is not forwarded to the application, which could cause possible reporting errors.

TN3270E statement

Use the TN3270E parameter statement to allow TN3270E functions to be negotiated by Telnet. If NOTTN3270E is specified, all TN3270E functions, such as printer support and client response, are disabled.

Telnet is initialized with a value of TN3270E.

The TN3270E and NOTTN3270E statements can be coded in the TELNETGLOBALS, TELNETPARMS, or PARMSGROUP statement block. See [“Rules for Telnet parameter statements”](#) on page 499 for more information about the hierarchy of parameter values.

The NOTN3270E value is useful in the unlikely case there are a significant number of clients that cannot tolerate negotiating for a TN3270E connection. Most clients do not have a problem with the TN3270E specification in the server, but, in the unlikely case that some do, specify and map NOTN3270E to that set of clients.

Syntax

Parameters

This statement has no parameters.

TNSACTIONS statement

Use the optional TNSACTIONS statement to configure the SNMP TN3270E Telnet subagent.

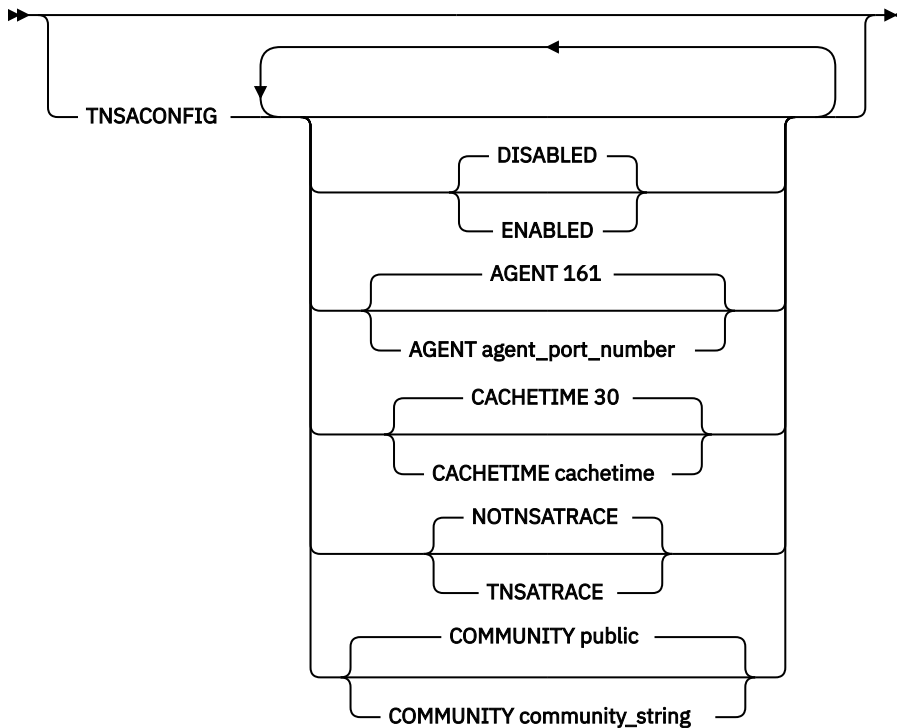

The Telnet defaults are:

- DISABLED
- AGENT 161
- COMMUNITY PUBLIC
- NOTNSATRACE
- CACHETIME 30

Restrictions:

- The TNSACTIONS statement can be coded only in the TELNETGLOBALS statement block.
- No parameters can change while the Telnet subagent is active. To make a change, the Telnet subagent must be disabled and then enabled again with the new parameter values.

Syntax

Parameters

AGENT

A port number in the range 1 - 65 535 used in establishing communication with the SNMP agent. For the Telnet SNMP subagent to communicate with the z/OS CS SNMP agent, the port number specified must match the port number specified on the -p parameter when the SNMP agent is started. See [“OSNMPD parameters” on page 1175](#) for a description of how to specify the port when the SNMP agent is started.

CACHETIME

Amount of time in seconds to elapse before rebuilding the MIB object tables. The valid range is 0 - 99 999 999.

COMMUNITY

A character string 1- 32 characters in length used as the community name (or password) in establishing contact with the SNMP agent. Because the community name is case sensitive, it is not converted to uppercase by profile processing. It cannot contain any imbedded white space or control characters (such as blank, tab, end of line, or end of file) and cannot contain any imbedded semicolons (semicolons are treated as comment delimiters). For the Telnet SNMP subagent to communicate with the z/OS Communications Server SNMP agent, the community name specified on the COMMUNITY keyword must match one that is defined in the PW.SRC or OSNMPD.CONF data set used by the SNMP agent or specified on the -c parameter when the SNMP agent is started.

For more information about how the community name is used to permit access to the SNMP agent, see [Step 1: Configure the SNMP agent \(OSNMPD\)](#), in [z/OS Communications Server: IP Configuration Guide](#).

DISABLED|ENABLED

DISABLED specifies that you do not require any of the SNMP MIB data supported by the Telnet subagent. By default, the Telnet SNMP subagent is not started during Telnet initialization. If specified using the VARY TCPIP, OBEYFILE command, this statement indicates that the currently active Telnet subagent task should be terminated. SNMP MIB objects supported by the z/OS CS SNMP agent and subagents other than the Telnet SNMP subagent are still available. For information about which MIB

objects are supported by the SNMP agent and subagent, see [z/OS Communications Server: IP User's Guide and Commands](#).

ENABLED indicates that the Telnet SNMP subagent should be started at the completion of profile processing, either of the initial profile or of the data set referenced on a VARY TCP/IP,,OBEYFILE command.

NOTNSATRACE|TNSATRACE

TNSATRACE generates trace points throughout Telnet subagent processing in addition to tracing data passed between the Telnet subagent and the agent, Telnet, and TCP/IP stack. The trace data is written to the syslog daemon.

UNLOCKKEYBOARD statement

Use the UNLOCKKEYBOARD statement to customize an unlock keyboard sequence being forwarded to the client from the host application.

Telnet is initialized with a value of UNLOCKKEYBOARD BEFOREREAD TN3270BIND.

The UNLOCKKEYBOARD statement can be coded in the TELNETGLOBALS, TELNETPARMS, or PARMSGROUP statement block. See [“Rules for Telnet parameter statements” on page 499](#) for more information about the hierarchy of parameter values.

Syntax

Parameters

BEFOREREAD

Indicates that when conditions warrant, an unlock keyboard sequence is sent to the client before forwarding a read command from the host application.

AFTERREAD

Indicates that when conditions warrant, an unlock keyboard sequence is sent to the client after forwarding a read command from the host application.

TN3270BIND

Indicates that when a BIND from the VTAM host application is received by Telnet for a TN3270 connection, a clear screen and an unlock keyboard is sent to the client.

NOTTN3270BIND

Indicates that when a BIND from the VTAM host application is received by Telnet for a TN3270 connection, neither a clear screen, nor an unlock keyboard are sent to the client.

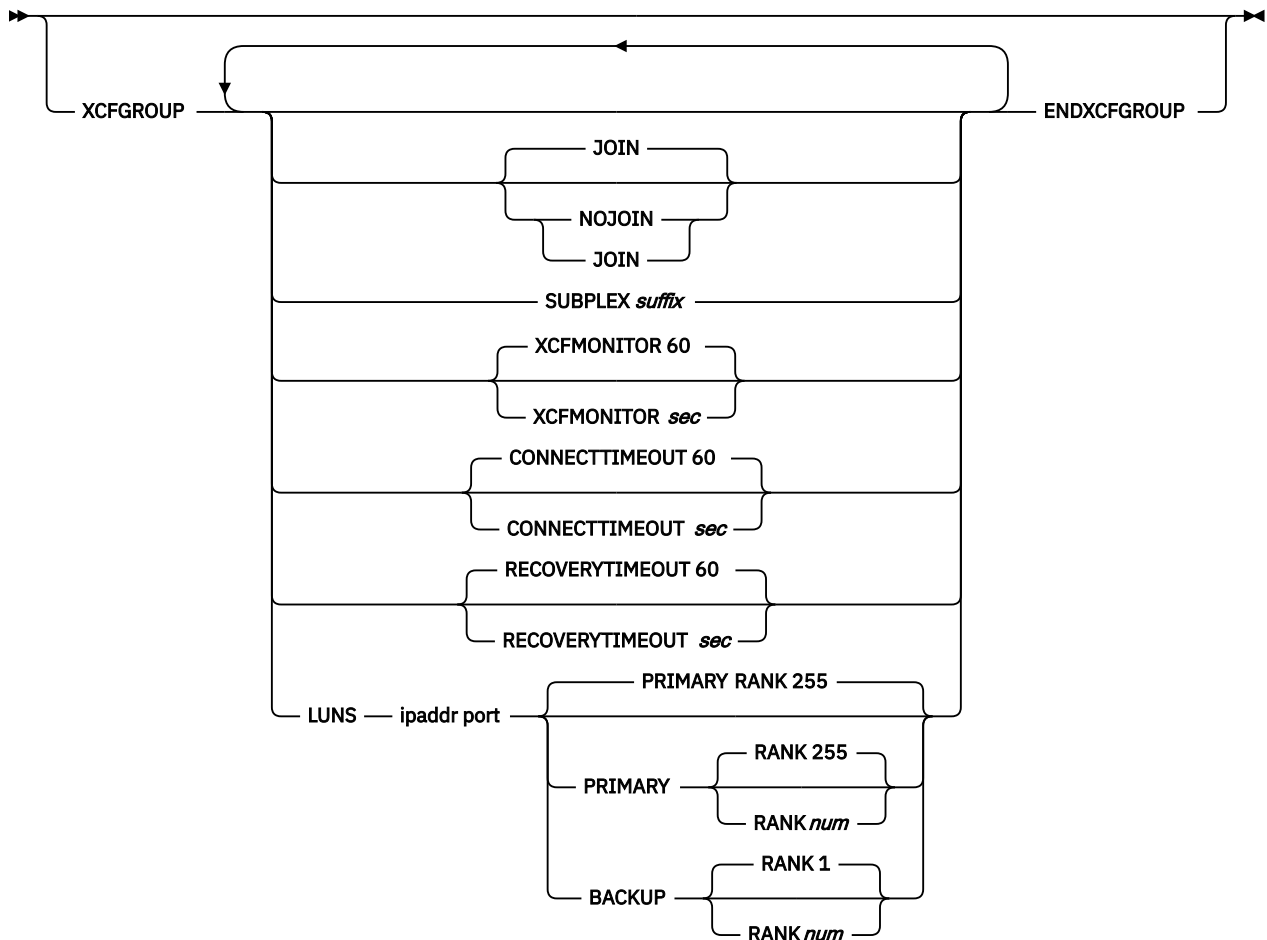

XCFGROUP statement

Use the optional XCFGROUP statement block to define and join the Telnet XCF group and to provide parameter values for the shared LU name management services. When an XCF Telnet joins the Telnet XCF group, that XCF Telnet can support the LU name server (LUNS) function, the LU name requester (LUNR) function, or both, based on which parameters are coded in the XCFGROUP statement and the BEGINVTAM block.

If the XCFGROUP statement is not coded, Telnet is initialized with the NOJOIN parameter.

The XCFGROUP statement can be coded only in the TELNETGLOBALS statement block. See “Rules for Telnet parameter statements” on page 499 for more information about the hierarchy of parameter values.

Syntax

Parameters

JOIN

Specifies that this Telnet should join the Telnet XCF group. Telnet uses only the XCF features available at the XCF-local level of functionality; the system does not need to be a member of a sysplex. Members of the XCF group are visible from any member of the group in XCF group status displays. A Telnet member of the XCF group is a potential LUNS if the LUNS parameter is coded. A member is a LUNR if shared LU names are defined in the BEGINVTAM block.

NOJOIN

Specifies that this Telnet should not join the Telnet XCF group. XCF group status displays are not available from this Telnet and this Telnet is not be visible in XCF group status displays from any member of the XCF group. This Telnet cannot become a LUNR and cannot define shared LU name objects.

SUBPLEX *suffix*

Specifies the character suffix (1 - 4 characters in length) to use for the Telnet XCF group name and ENQUE names to partition a sysplex into multiple Telnet subplexes. Telnet is initialized to use the string EZZTLUNS. The specified suffix is right-aligned and overlays the end of this string to form unique subplex strings. For example, if the suffix value is 23, Telnet joins XCF group EZZTLU23.

XCFMONITOR *sec*

Sets the XCF monitor interval to the number of seconds that a LUNR attempts to establish a connection to the LUNS before quiescing its LUNR capabilities. At the specified time interval, Telnet

checks the health of the LUNS, LUNR, and XCF Telnet tasks and checks the health of the connection between the LUNS and LUNR. If any of these tasks or connections appear to be unresponsive, message EZZ6099I is issued and the X indicator is set to on under the PDMON column in the XCFGROUP display.

The valid values for this timer are in the range 10 - 3600.

CONNECTTIMEOUT sec

This parameter applies only to LUNR. Sets the monitor interval to the number seconds that a LUNR attempts to establish a connection to the LUNS before quiescing its LUNR capabilities. If the LUNR has not been able to connect to the LUNS within the amount of time, then the LUNR has not been able to connect with the LUNS, the LUNR drops all connections that are waiting in negotiation for an LU name and quiesces all ports that have shared groups. This action frees clients to reconnect to a working LUNR. The value 0 disables the connect timeout interval. Valid values are 0 or an integer in the range 10 - 99 999 999.

RECOVERYTIMEOUT sec

This parameter applies only to LUNR. Sets the number of seconds that a LUNR attempts to establish a connection to the recovering LUNS before dropping connections using shared LU names. When a LUNS takeover occurs and a new LUNS becomes available, each Telnet LUNR repeatedly attempts to connect to the new LUNS. The recovery of the LUNS cannot complete until all LUNRs have recognized the new LUNS and all LUNRs that have allocated LU names have connected to the new LUNS and re-registered all previously allocated shared LU names. If the LUNR does not successfully connect within the specified time, it drops all existing client connections that are using shared LU names. The recovery of the LUNS completes and shared shared LU name management resumes without this LUNR. The value 0 disables the recovery timeout interval.

Valid values are 0 or an integer in the range 10 - 99 999 999.

LUNS PRIMARY

Specifies that this Telnet becomes the active LUNS at job initiation if there is not already an active LUNS. If there is already an active LUNS, this Telnet becomes a standby. Telnet must join the XCF group to be a LUNS.

LUNS BACKUP

Specifies that this Telnet becomes a standby LUNS at job initiation. Telnet must join the XCF group to be a LUNS.

ipaddr

Specifies the IP address that this Telnet listens on for shared LU name management requests when the address becomes the active LUNS.

port

Specifies the port that this Telnet listens on for shared LU name management requests when the port becomes the active LUNS.

RANK

Specifies the takeover rank of this LUNS when it is in standby mode and the active LUNS fails. The standby LUNS with the highest rank becomes the new LUNS. If there is more than one standby LUNSS with the same rank, they compete for a sysplex scope ENQUEUE. The winner becomes the new LUNS, and the others return to standby mode. Valid values are in the range 1 - 255.

Telnet mapping statements in the Telnet profile

Mapping statements for Telnet are specified in the BEGINVTAM block. All mapping statements are optional for the BEGINVTAM block.

Some statements combine mapping and object functions. For example, DEFAULTLUS defines the LU GROUP Object and implicitly maps the group to the NULL Client Identifier. ALLOWAPPL defines the security level of application Objects and optionally provides LU mapping function.

[Table 34 on page 534](#) provides a list of Telnet mapping statements and the location of more information.

Table 34. Telnet mapping statements

Statement	Mapping statement	Client identifier	Object	See page
ALLOWAPPL	X		X	“ALLOWAPPL statement” on page 538
DEFAULTAPPL	X			“DEFAULTAPPL statement” on page 539
DEFAULTLUS and SDEFAULTLUS	X		X	“DEFAULTLUS or SDEFAULTLUS statement” on page 540
DEFAULTLUSSPEC and SDEFAULTLUSSPEC	X		X	“DEFAULTLUSSPEC or SDEFAULTLUSSPEC statement” on page 541
DEFAULTPRT and SDEFAULTPRT	X		X	“DEFAULTPRT or SDEFAULTPRT statement” on page 542
DEFAULTPRTSPEC and SDEFAULTPRTSPEC	X		X	“DEFAULTPRTSPEC or SDEFAULTPRTSPEC statement” on page 543
DESTIPGROUP		X		“DESTIPGROUP statement” on page 544
HNGROUP		X		“HNGROUP statement” on page 544
INTERPTCP	X			“INTERPTCP statement” on page 545
IPGROUP		X		“IPGROUP statement” on page 546
LINEMODEAPPL	X			“LINEMODEAPPL statement” on page 547
LINKGROUP		X		“LINKGROUP statement” on page 548
LUGROUP and SLUGROUP			X	“LUGROUP or SLUGROUP statement” on page 548
LUMAP	X			“LUMAP statement” on page 550
MONITORGROUP			X	“MONITORGROUP statement” on page 551
MONITORMAP	X			“MONITORMAP statement” on page 553
PARMSGROUP			X	“PARMSGROUP statement” on page 553
PARMSMAP	X			“PARMSMAP statement” on page 554
PORT				“PORT statement” on page 554
PRTDEFAULTAPPL	X			“PRTDEFAULTAPPL statement” on page 555
PRTGROUP and SPRTGROUP			X	“PRTGROUP or SPRTGROUP statement” on page 556
PRTMAP	X			“PRTMAP statement” on page 557
RESTRICTAPPL	X		X	“RESTRICTAPPL statement” on page 558

Table 34. Telnet mapping statements (continued)				
Statement	Mapping statement	Client identifier	Object	See page
USERGROUP		X		“USERGROUP statement” on page 560
USSTCP	X			“USSTCP statement” on page 561

Rules: Observe the following rules for BEGINVTAM statements:

- If the BEGINVTAM block represents more than one port, the first statement in the BEGINVTAM block must be the port designation statement.
- Telnet must have an application and Telnet LUs defined in order to connect to a host application.
- Object and Client Identifier group names can include any printable character except those in [Table 35 on page 535](#):

Table 35. Object and Client Identifier group name printable character exceptions		
Character	EBCDIC	Description
.	4B	Period
*	5C	Asterisk
;	5E	Semicolon
,	6B	Comma
=	7E	Equal

- Any Object or Client Identifier group name must be defined before it can be specified on a mapping statement. Otherwise, the group name is interpreted as a linkname.
- LUGROUPs and PRTGROUPs must be mapped to a Client Identifier to be used.
- If one element in a group is not valid, Telnet flags the element that is not valid and processes the statement as if the element were not part of the statement. If all elements are not valid, Telnet issues a debug message indicating the GROUP is empty.
- The second instance of the Client Identifier in the second group is ignored and a message is issued. For example:

```
IPGROUP ABC 1.1.1.1 2.2.2.2 ENDIPGROUP
IPGROUP XYZ 2.2.2.2 3.3.3.3 ENDIPGROUP
```

The second IPGROUP statement generates a debug warning message indicating that "2.2.2.2" is already defined in an IPGROUP.

- An IPGROUP with a subnet mask of 0.0.0.0:0.0.0.0 specified matches all clients.

Rules for LU name specification

Rules: Observe the following rules for LU name specification:

- The first character must be in the range A through Z, @, #, or \$. In addition, remaining characters can also be numeric (any single digit 0 through 9). Unprintable characters are not allowed. If a name that is not valid is found, an error message is issued and the statement is ignored.
- LUs can be defined as a range. Use the following syntax to specify a range of LUs:

➡ *LowerRange..UpperRange* ➡

- No spaces are allowed within a range definition.

- *UpperRange* must be greater than the *LowerRange*.
- The lengths of *LowerRange* or *UpperRange*, and *rangerule* must be the same and each must be less than or equal to eight characters.
- All LUs in the range must be valid and defined to VTAM for a successful session.
- The number of LU names in one range is limited to 4 294 967 295. The total number of LU names in the group is also limited to 4 294 967 295. Storage is not used until the LU name is assigned to the connection.
- The *rangerule* represents the variant used for wildcarding. For example:

```
TCP000A0..TCP9F$ZZ..FFNX?AB
```

where:

F

The position is fixed and does not change.

A

Alphabetic range.

N

Numeric range.

B

Alphanumeric range.

X

Hexadecimal range.

?

Alphanumeric including national characters @, #, and \$.

If an incorrect range definition is parsed, it is ignored and a debug warning message is issued.

Result: The range specification AB100..CB299..AFNNN defines AB100-AB999 (900), BB000-BB999 (1000) and CB000-CB299 (300) (2200 names). If a specification of AB100-AB299, BB100-BB299 and CB100-CB299 (600 names) is desired, then two range specifications are required: AB100..CB199..AFFNN AB200..CB299..AFFNN.

See [z/OS Communications Server: IP Configuration Guide](#) for LU range usage examples.

- If the range rule is omitted, Telnet assumes the following style, where the *LowerRange* and *UpperRange* values must be all numeric or all alphabetic:

```
LuBase+LowerRange..LuBase+UpperRange
```

Client identifier types and definitions

Table 36 on page 536 shows the Client Identifier types and their definitions available for use on mapping statements.

Table 36. Client identifier types and definitions	
Client identifier type	Definition
USERID	The client User ID derived from the client certificate at connection time when the connection is protected by AT-TLS and the relevant TTLSEnvironmentAction or TTLSConnectionAction policy statement specifies HandshakeRole ServerWithClientAuth.
HOSTNAME	The completely qualified client host name.
IPADDR	The client IP address expressed in dotted decimal form. This can be an IPv4 address only.
USERGRP	The USERGROUP name that contains exact or wildcard client user IDs.

Table 36. Client identifier types and definitions (continued)

Client identifier type	Definition
HNGRP	The HNGROUP name that contains exact or wildcard client host names.
IPGRP	The IPGROUP name that contains exact or subnetted client IP addresses.
DESTIP	The destination IP address expressed in dotted decimal form.
LINKNAME	The link or interface name defined by the LINK or INTERFACE statement in PROFILE.TCPIP.
DESTIPGRP	The DESTIPGROUP name that contains exact or subnetted destination IP addresses.
LINKGRP	The LINKGROUP object name that contains exact or wildcard link or interface names.
NULL	Not coded, but listed here for completeness. This Client Identifier type indicates that no Client Identifier was specified. This is valid for the DEFAULTAPPL, LINEMODEAPPL, USSTCP, and INTERPTCP mapping statements. It is the implied Client Identifier for the DEFAULTLUS, DEFAULTLUSSPEC, DEFAULTPRT, and DEFAULTPRTSPEC Object statements.

See [z/OS Communications Server: IP Configuration Guide](#) for Object selection priority based on Client Identifiers.

Rules for client identifier specification

Observe the following rules for client identifier specification:

- When the Client Identifier is a single entity on a mapping statement rather than part of a group, no wildcarding is allowed.
- A *group name* must be defined with the appropriate statement before it can be specified on a MAPPING statement. Otherwise, the name is assumed to be a link or interface name.
- User ID and destination IP address require the *clid_type* keyword to correctly identify the Client Identifier. If *clid_type* is not used, a user ID Client Identifier is assumed to be a link or interface name and a destination IP address Client Identifier is assumed to be the traditional client (source) IP address.
- Client Identifiers of a particular type, such as IP address or host name, can be defined within only one group of that type. If the Client Identifier is defined in more than one group, a debug warning message is issued showing the Client Identifier that is ignored and the name of the owning group. No error is issued if a Client Identifier is listed twice in the same group.

See [z/OS Communications Server: IP Configuration Guide](#) for exact mapping rules.

Rules for host name specification

Observe the following rules for host name specification:

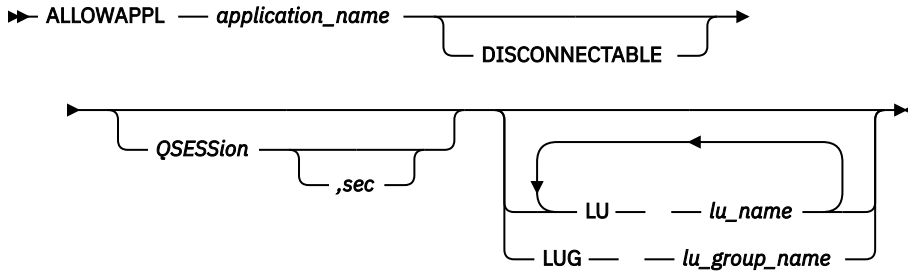

- Host name specification requires that Telnet be able to resolve a host name from an IP address by use of the resolver. To do this, a valid TCPIP.DATA data set must be provided. For overview information about TCP/IP application configuration files, see [z/OS Communications Server: IP Configuration Guide](#) for a description of how TCPIP.DATA is located. Telnet uses the native MVS sockets search order to find a resolver. Neither the z/OS environmental variable (Resolver_Config) nor the /etc/resolv.conf z/OS UNIX is used when searching for TCPIP.DATA.
- The Telnet client IP address and port are automatically added to the z/OS Communications Server SNA displays. An HNGROUP statement is required if you also want the DNS name of the client. If you are mapping objects using host names, the DNS names of the Telnet clients is provided to the z/OS Communications Server SNA displays automatically. This occurs automatically because the names must have been resolved for mapping purposes. If you are not mapping by host names, but want

to have Telnet client host names provided to the z/OS Communications Server SNA displays, add an HNGROUP name and ENDHGGROUP name to your Telnet profile. Choose an unused host name (such as AA.AA). If you add the HNGROUP statement to get DNS name resolution, some delay might occur during connection processing for name resolution.

ALLOWAPPL statement

Use the *optional* ALLOWAPPL mapping and security statement to specify which VTAM application names clients can access and optionally, which LU names are valid.

Syntax

Parameters

application_name

The host application name, as specified in VTAMLST.

Single-character position wildcards (%) are permitted anywhere in the application name and the multi-character wildcard (*) is permitted at the end of an application name. For example, A%CICS®* allows connections to A1CICS01, A1CICS02, ABCICS4A, and so on. A single * allows all applications.

DISCONNECTABLE

When DISCONNECTABLE is specified, VTAM notifies the application to disconnect, rather than log off a user, when the session is dropped.

QSESSion

Indicates this application queues a session request when passing the session to another primary application. When Telnet receives an UNBIND of the new session, Telnet waits for a BIND to reestablish the original queued session.

sec

When QSESSion is coded, this value determines the number of seconds Telnet waits before checking whether a BIND was received. The range is 1 - 99 999 999. If no BIND is received in the time specified, Telnet stops waiting and continues cleaning up the connection as if QSESSion had not been coded. There is no default value. If sec is not coded, the connection never checks whether a BIND is received. Telnet waits until a BIND is received or the connection is dropped.

LU *lu_name*

The logical name of the Telnet terminal LU. This parameter allows you to optionally specify which terminal LUs can be used to establish a session with the named VTAM host application.

LUG *lu_group_name*

The name of the LUGROUP or PRTGROUP. This option allows you to specify an LUGROUP or PRTGROUP, where any LU in the group can be used to establish a session with the named VTAM host application. If the same name defines both an LUGROUP and a PRTGROUP, the LUGROUP is used. The group can be a new group consisting of a combination of names or range list names from existing LUGROUPs and PRTGROUPs. This allows both terminals and printers to be on the same ALLOWAPPL statement.

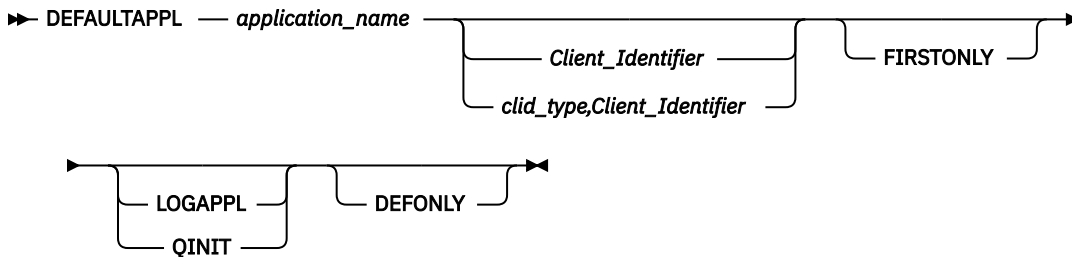

Usage notes

- Applications that perform CLSDST PASS also require an ALLOWAPPL or RESTRICTAPPL statement for the target application.
- LU and LUG keywords are mutually exclusive. If both are specified in any order, only the last LUG is accepted and processed. If multiple LUG keywords are specified, only the last is accepted and processed.
- If the LU assigned to the connection is defined in LU groups mapped by both a LUG statement and an LUMAP/PRTMAP statement, neither LU group can be defined as an LU exit.

DEFAULTAPPL statement

Use the *optional* DEFAULTAPPL mapping statement to map the initial application to be tried when a Telnet client establishes a connection other than linemode. The application might be a particular VTAM application such as CICS or could be a network solicitor or front-end menu system such as TPX. DEFAULTAPPL allows a user to establish a session with an application without having to know the actual VTAM name of the application.

Syntax

Parameters

application_name

The host application name, as specified in VTAMLST. The *application_name* can be network qualified in the format of a 1- to 8-character name of the network ID separated by a period (.), followed by a 1- to 8-character application name.

clid_type

Specifies the type of Client Identifier. It is required if USERID or DESTIP are specified. See [“Rules for client identifier specification”](#) on page 537 for details.

Client_Identifier

One of several Client Identifiers. See [“Client identifier types and definitions”](#) on page 536 for details. If no Client Identifier is specified, then it is considered the NULL Client Identifier.

FIRSTONLY

When FIRSTONLY is specified, a solicitor or USSMSG10 screen is sent to the client after logoff from a default session when LUSESSIONPEND is coded. When FIRSTONLY is not specified, Telnet always requests a new session to the default application after logoff from the session when LUSESSIONPEND is coded. If LUSESSIONPEND is not coded, the connection is dropped.

LOGAPPL

When LOGAPPL is specified, a session request to a host application that is not active is queued in VTAM instead of rejected. Telnet keeps the ACB open for the LU representing the client. When the application becomes active, VTAM initiates a session between the application and the Telnet LU.

QINIT

Indicates that session requests should be queued, and when logging off the default application, Telnet should redrive the default application instead of issuing a USSMSG10 or Solicitor screen.

DEFONLY

When DEFONLY is specified, the client is blocked from specifying any application name other than the one specified on the default application statement.

Usage notes

- Always map a unique Client Identifier on each DEFAULTAPPL statement. Otherwise, the last DEFAULTAPPL mapping for the Client Identifier is used.
- If a USS table is mapped to the Client based on a higher priority Client Identifier, the DEFAULTAPPL statement is ignored.

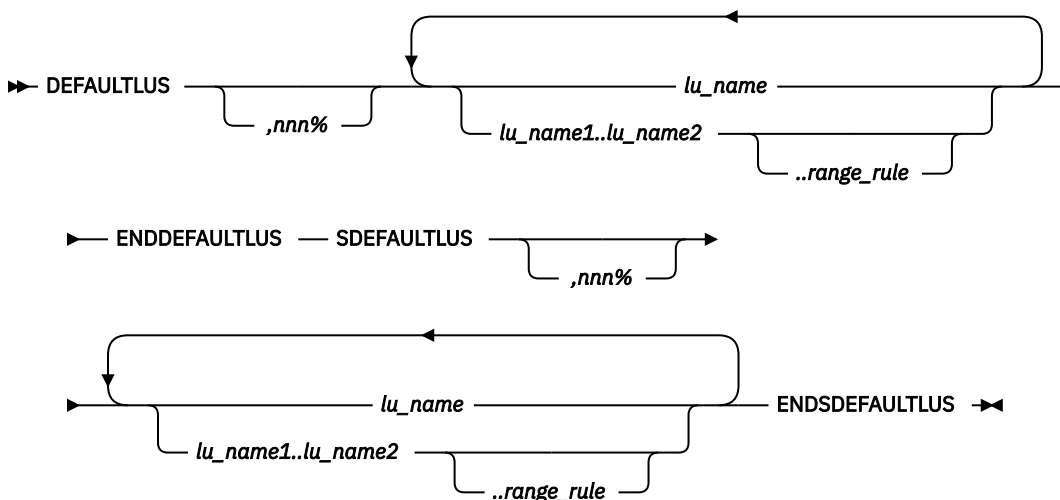

DEFAULTLUS or SDEFAULTLUS statement

Use the *optional* DEFAULTLUS or SDEFAULTLUS object and mapping statement to define a list or range of LUs that have a default mapping to the NULL client identifier. This LU pool is used by a terminal emulator that is requesting a generic connection if no other LU group maps generically to the client. The SDEFAULTLUS statement defines shared LU names rather than private ones.

Restrictions:

- This Telnet must have joined the XCF group to define shared objects. An active Telnet LU name server (LUNS) must exist in order for the profile to be processed and for the shared LUs to be usable.
- A profile can have either DEFAULTLUS or SDEFAULTLUS defined, but not both.

Syntax

Parameters

nnn%

Checks the capacity remaining in the group when Telnet assigns an LU from that group. A message is issued when the specified percentage is reached. After the group exceeds the specified capacity, no other message is issued. After the capacity being used drops below 10 percent of the total capacity check amount, another capacity warning message is issued. Leave a blank space between DEFAULTLUS or SDEFAULTLUS and the comma (,) that is part of the capacity field.

lu_name

The name of the terminal LU.

lu_name1..lu_name2

A range of terminal LUs.

range_rule

The wildcard method used for each character position.

Usage notes

- See “Rules for LU name specification” on page 535 for LU name and LU range specification rules.

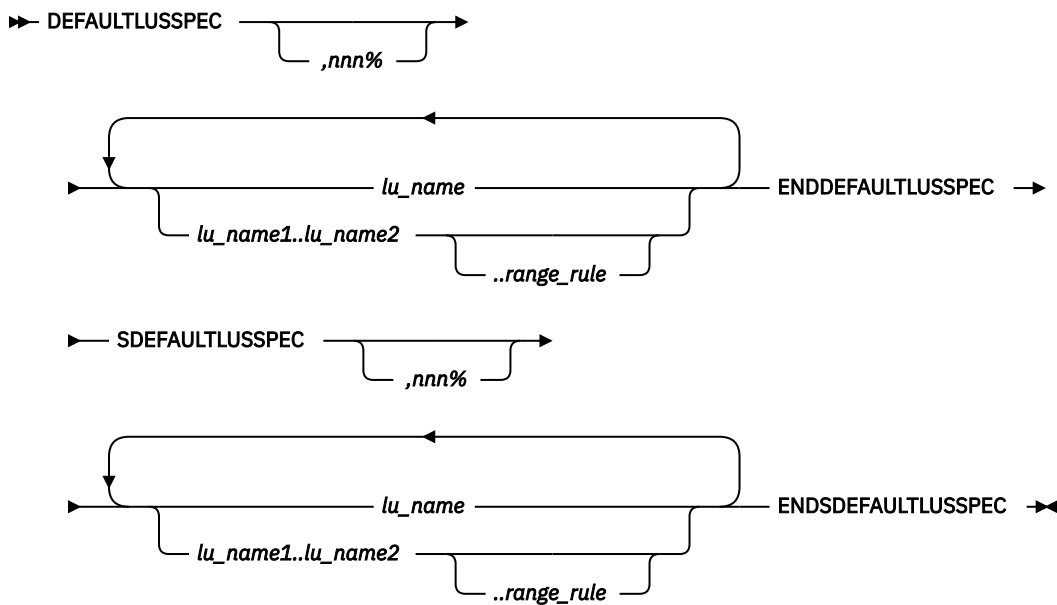

DEFAULTLUSSPEC or SDEFAULTLUSSPEC statement

Use the *optional* DEFAULTLUSSPEC or SDEFAULTLUSSPEC object and mapping statements to define a list or range of LUs that have a default mapping to the NULL client identifier. This pool is used by a terminal emulator that is requesting a specific connection if no other LU group maps specifically or generically to the client. The SDEFAULTLUSSPEC statement defines shared LU names rather than private ones.

Restrictions:

- This Telnet must have joined the XCF group to define shared objects. An active Telnet LU name server (LUNS) must exist in order for the profile to be processed and for the shared LUs to be usable.
- A profile can have either DEFAULTLUSSPEC or SDEFAULTLUSSPEC defined, but not both.

Syntax

Parameters

nnn%

Checks the capacity remaining in the group when Telnet assigns an LU from that group. A message is issued when the specified percentage is reached. After the group exceeds the specified capacity, no other message is issued. After the capacity being used drops below 10 percent of the total capacity check amount, another capacity warning message is issued. Leave a blank space between DEFAULTLUS or SDEFAULTLUS and the comma (,) that is part of the capacity field.

lu_name

The name of the terminal LU.

lu_name1..lu_name2

A range of terminal LUs.

range_rule

The wildcard method used for each character position.

Usage notes

See [“Rules for LU name specification” on page 535](#) for LU name and LU range specification rules.

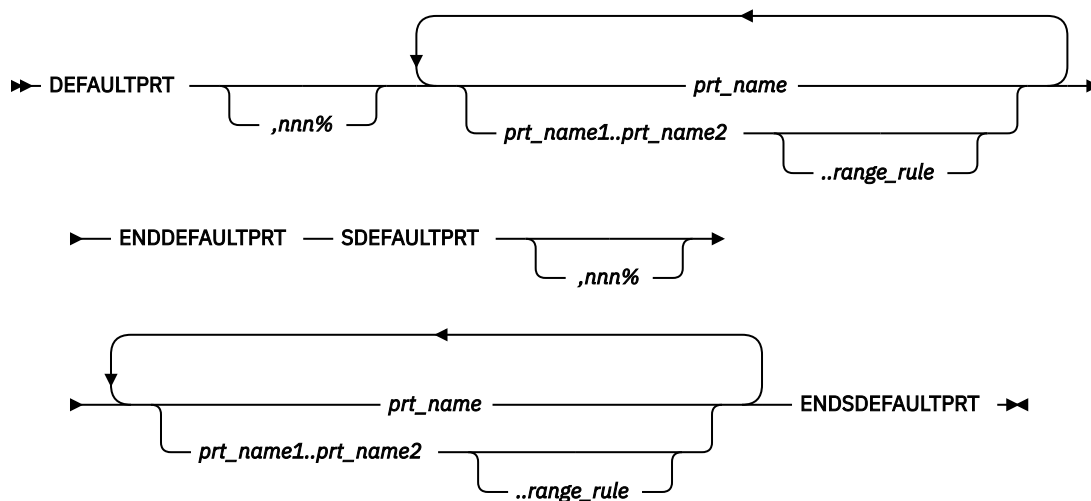

DEFAULTPRT or SDEFAULTPRT statement

Use the *optional* DEFAULTPRT or SDEFAULTPRT object and mapping statements to define a list or range of printer LUs that have a default mapping to the NULL client identifier. This LU pool is used by a printer emulator that is requesting a generic connection if no other printer LU group maps to the client. The SDEFAULTPRT statement defines shared LU names rather than private ones.

Restrictions:

- This Telnet must have joined the XCF group to define shared objects. An active Telnet LU name server (LUNS) must exist in order for the profile to be processed and for the shared LUs to be usable.
- A profile can have either DEFAULTPRT or SDEFAULTPRT defined, but not both.

Syntax

Parameters

nnn%

Checks the capacity remaining in the GROUP when Telnet assigns an LU from that group. A message is issued when the specified percentage is reached. After the group exceeds the specified capacity, no other message is issued. After the capacity drops below 10 percent of the total capacity check amount, another capacity warning message is issued. Leave a blank space between DEFAULTLUS or SDEFAULTLUS and the comma (,) that is part of the capacity field.

prt_name

The name of the printer LU.

prt_name1..lu_name2

A range of printer LUs.

range_rule

The wildcard method used for each character position.

Usage notes

See [“Rules for LU name specification” on page 535](#) for LU name and LU range specification rules.

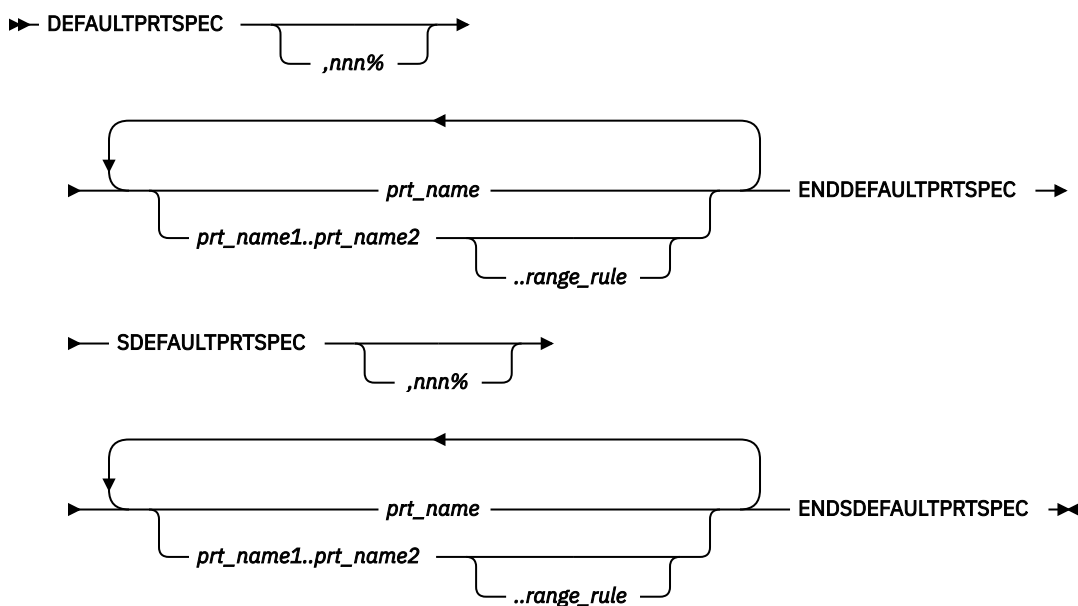

DEFAULTPRTSPEC or SDEFAULTPRTSPEC statement

Use the *optional* DEFAULTPRTSPEC or SDEFAULTPRTSPEC object and mapping statements to define a list or range of printer LUs with a default mapping to the NULL client identifier. This LU pool is used by a printer emulator requesting a specific connection if no other printer LU group maps specifically or generically to the client. The SDEFAULTPRTSPEC statement defines shared LU names rather than private ones.

Restrictions:

- This Telnet must have joined the XCF group to define shared objects. An active Telnet LU name server (LUNS) must exist in order for the profile to be processed and for the shared LUs to be usable.
- A profile can have either DEFAULTPRTSPEC or SDEFAULTPRTSPEC defined, but not both.

Syntax

Parameters

nnn%

Checks the capacity remaining in the group when Telnet assigns an LU from that group. A message is issued when the specified percentage is reached. After the group exceeds the specified capacity, no other message is issued. After the capacity drops below 10 percent of the total capacity check amount, another capacity warning message is issued. Leave a blank space between DEFAULTLUS or SDEFAULTLUS and the comma (,) that is part of the capacity field.

prt_name

The name of the printer LU.

prt_name1..lu_name2

A range of printer LUs.

range_rule

The wildcard method used for each character position.

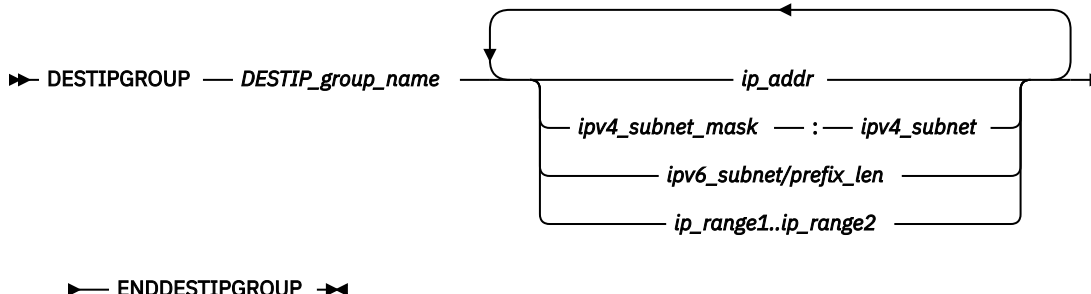

Usage notes

See [“Rules for LU name specification”](#) on page 535 for LU name and LU range specification rules.

DESTIPGROUP statement

Use the *optional* DESTIPGROUP Client Identifier statement to define a group of destination IP addresses. The group name can be used on several mapping statements.

Syntax

Parameters

DESTIP_group_name

The group name (up to 16 characters) that contains the destination IP addresses or subnets.

ipv4_subnet_mask:ipv4_subnet

An IPv4 format subnet. The *ipv4_subnet_mask* is a bit mask (expressed in dotted-decimal form) defining the subnetwork mask for a network route. The bits must be contiguous and start in the leftmost bit. The *subnet_mask* indicates the significant portion of the subnet. The subnet and an incoming IP address are each ANDed with the *subnet_mask* and then compared with each other to determine a match.

ipv6_subnet/prefix_len

An IPv6 format subnet. The *prefix_len* indicates how many significant bits there are starting from the leftmost bit. The subnet and an incoming IP address are each ANDed with the *prefix_len* number of bits and then compared with each other to determine a match.

ip_addr

The exact IP address of the destination host address that is the destination for a Telnet connection.

ip_range1..ip_range2

A range of IP addresses.

Restriction: Only the last octet of the IPv4 address and the last two hexadecimal bytes of the IPv6 address can be used as variables for the range.

Usage notes

- Any given IP address or combination of IP subnet mask and IP subnet can only appear once within all destination IP groups.
- The subnet and mask combination has no restrictions, including specific class address specifications.

HNGROUP statement

Use the *optional* HNGROUP Client Identifier statement to define a group of host names. The group name can be used on several mapping statements.

Tip: To cause the host name to be present in the control vector (CV64) information, or to make the host name that is used to inform the mechanism be associated with the CHECKCLIENTCONN statement, add a dummy HNGROUP-ENDHNGROUP statement block.

Syntax

Parameters

hngroup_name

The group name (up to 16 characters) that contains the host names.

hn_name

An exact, completely qualified host name or a wildcard host name.

Wildcards can be specified in two ways:

- Use a single asterisk (*) to indicate that any value is acceptable for a particular qualifier in a particular position within the host name. For example, *.IBM.COM matches USER1.RALEIGH.IBM.COM, but does not match USER1.TCP.RALEIGH.IBM.COM because this name includes an extra qualifier.

Restriction: Use of a single asterisk cannot follow any non wildcarded name. For example, RALEIGH/*.COM is not allowed.

- Use a double asterisk (**) to indicate that any number of qualifiers are acceptable to the left of the asterisks. For example, **.IBM.COM matches USER1.IBM.COM, USER1.RALEIGH.IBM.COM, and USER1.TCP.RALEIGH.IBM.COM.

Both wildcard techniques require that the entire qualifier be wildcarded. For example, *USER.IBM.COM is not a valid use of a wildcard. In this case, use *.IBM.COM instead.

Usage notes

- Any given host name or wildcard host name can only appear one time within all HNGROUPs.
- Results in DNS hostname resolution for every new connection processed by the TN3270 server.
- See [“Rules for host name specification” on page 537](#) for host name resolution and display information.

INTERPTCP statement

Use the *optional* INTERPTCP mapping statement to allow you to map a customized interpret table to a Client Identifier. This table is used to interpret incoming USS commands before the USS command processor is invoked. If the input string does not match any interpret table entry, the USS command processor parses the input string.

Syntax

Parameters

table_name

The name of the interpret table load module.

clid_type

Specifies the type of Client Identifier. It is required if USERID or DESTIP are specified. See [“Rules for client identifier specification”](#) on page 537 for details.

Client_Identifier

One of several Client Identifiers. See [“Client identifier types and definitions”](#) on page 536 for details. If no Client Identifier is specified, then it is considered the NULL Client Identifier.

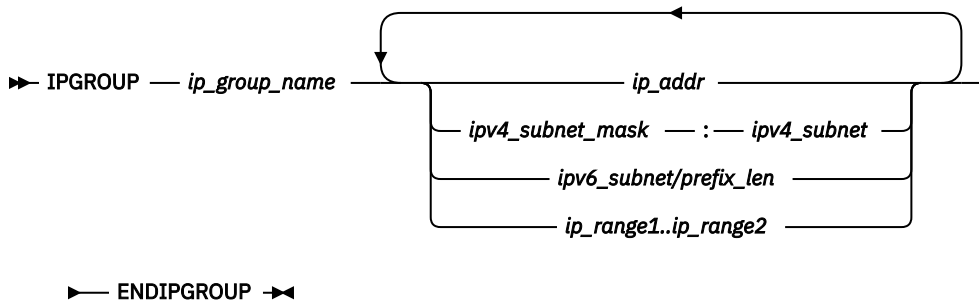

Usage notes

- An assembled interpret table load module from VTAM can be used or one can be created. See [z/OS Communications Server: IP Configuration Guide](#) for coding details. Also see [“Telnet INTERPRET table setup”](#) on page 570.
- Always map a unique Client Identifier on each INTERPTCP statement. Otherwise, the last INTERPRET table mapping for the Client Identifier is used.
- The most common setup error is to fail to include the table load module in a load library accessible by TCP/IP.
- The INTERPRET table is used to check USS commands only. Therefore, INTERPRET table function is provided only for connections that are using a USS table.

IPGROUP statement

Use the *optional* IPGROUP Client Identifier statement to define a group of IP addresses. The group name can be used on several mapping statements.

Syntax

Parameters

ip_group_name

The group name (up to 16 characters) that contains the Client IP addresses or subnets.

ipv4_subnet_mask:ipv4_subnet

An IPv4 format subnet. The *ipv4_subnet_mask* is a bit mask (expressed in dotted-decimal form) defining the subnetwork mask for a network route. The bits must be contiguous and start in the leftmost bit. The *subnet_mask* indicates the significant portion of the subnet. The subnet and an incoming IP address are each ANDed with the *subnet_mask* and then compared with each other to determine a match.

ipv6_subnet/prefix_len

An IPv6 format subnet. The *prefix_len* indicates how many significant bits there are starting from the leftmost bit. The subnet and an incoming IP address are each ANDed with the *prefix_len* number of bits and then compared with each other to determine a match.

ip_addr

The exact IP address of a particular client.

ip_range1..ip_range2

A range of IP addresses.

Restriction: Only the last octet of the IPv4 address and the last two hexadecimal bytes of the IPv6 address can be used as variables for the range.

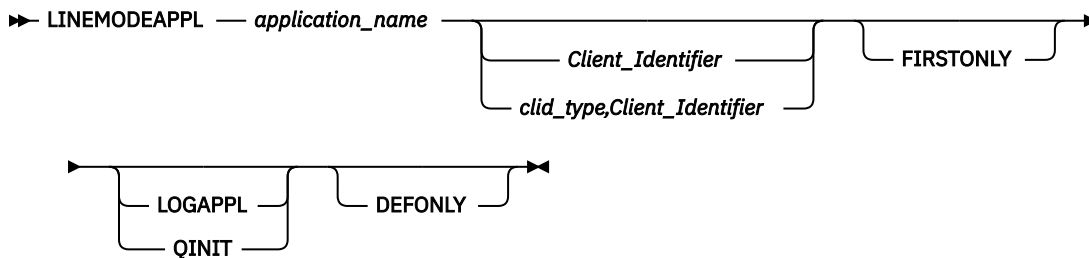

Usage notes

- Any given client IP address can only appear one time within all IP Groups. A given combination of IP subnet mask and IP subnet can only appear once within all IP groups.
- The subnet and mask combination has no restrictions, including specific class address specifications.

LINEMODEAPPL statement

Use the *optional* LINEMODEAPPL mapping statement to map the initial application to be attempted when a Telnet client establishes a linemode connection.

Syntax

Parameters

application_name

The host application name, as specified in VTAMLST. The *application_name* can be network qualified in the format of a 1- to 8-character name of the network ID separated by a period (.), followed by a 1- to 8-character application name.

clid_type

Specifies the type of Client Identifier. It is required if USERID or DESTIP are specified. See [“Rules for client identifier specification”](#) on page 537 for details.

Client_Identifier

One of several Client Identifiers. See [“Client identifier types and definitions”](#) on page 536 for details. If no client identifier is specified, then it is considered the NULL client identifier.

FIRSTONLY

When FIRSTONLY is specified, a solicitor or USSMSG10 screen is sent to the client after logoff from a default session when LUSESSIONPEND is coded. When FIRSTONLY is not specified, Telnet always requests a new session to the default application after logoff from the session when LUSESSIONPEND is coded. If LUSESSIONPEND is not coded the connection is dropped.

LOGAPPL

When LOGAPPL is specified, a session request to a host application that is not active is queued in VTAM instead of rejected. Telnet keeps the ACB open for the LU representing the client. When the application becomes active, VTAM initiates a session between the application and the Telnet LU.

QINIT

Indicates that session requests should be queued, and when logging off the default application, Telnet should redrive the default application instead of issuing a USSMSG10 or Solicitor screen.

DEFONLY

When DEFONLY is specified, the client is blocked from specifying any application name other than the one specified on the default application statement.

Usage notes

Always map a unique Client Identifier on each LINEMODEAPPL statement. Otherwise, the last LINEMODEAPPL mapping for the Client Identifier is used.

LINKGROUP statement

Use the *optional* LINKGROUP Client Identifier statement to define a group of link or interface names. The group name can be used on several mapping statements.

Syntax

Parameters

linkgroup_group_name

The group name (up to 16 characters) that contains the exact link or interface names or wildcard link or interface names.

linkname

An exact link or interface or a wildcard link or interface name.

Linknames can be wildcarded when specified in a group.

- % or ? is a single-character position wildcard. It can be placed anywhere.
- * is a multi-position wildcard. It can only be placed at the end of the linkname.
- The two wildcard types can be used together. For example, L%%V5* is a valid wildcard name.

The position of the single wildcard (%) is used first to determine the most specific match. For example, the following wildcard names are checked in the order listed:

- C5CLINK*
- C5C%%%%*
- C5%LINK*
- C%CLINK*
- C%CLI%K*
- C%CLI%*
- C%CL%NK*
- C*

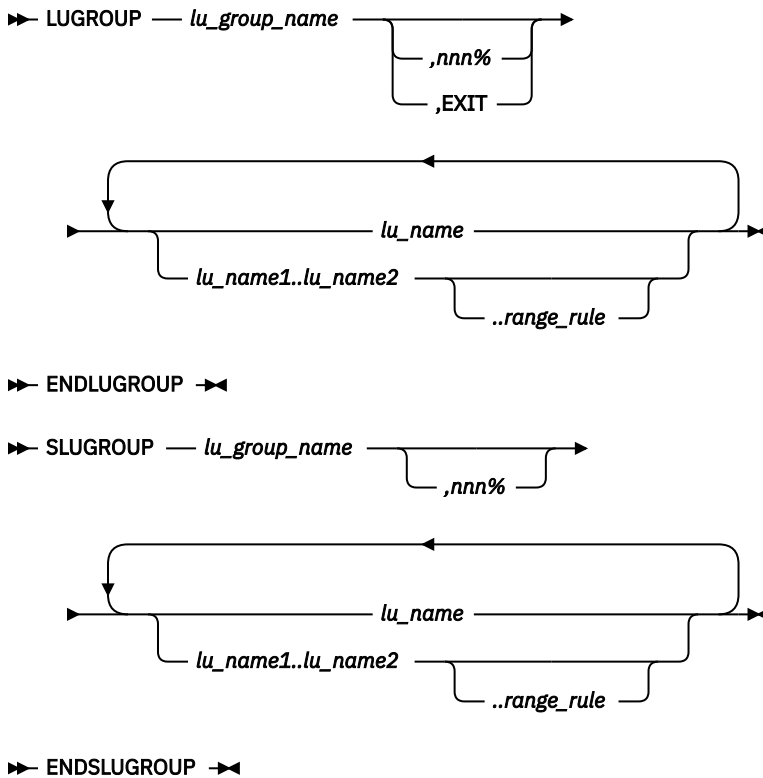

LUGROUP or SLUGROUP statement

Use the *optional* LUGROUP or SLUGROUP object statements to define a group of LUs. These group names can be used on the LUMAP statement to represent an LU pool. The SLUGROUP statement defines shared LU names rather than private ones.

Restrictions:

- This Telnet must have joined the XCF group to define shared LUs. An active Telnet LU name server (LUNS) must exist for the profile to be processed and for the shared LUs to be usable.
- All *lu_group_name* values on one profile must be unique, even though a profile can have both LU group names and shared LU group names defined.

Syntax

Parameters

lu_group_name

The group name (1 - 8 characters in length) that contains the terminal LUs.

nnn%

Checks the capacity remaining in the LUGROUP or SLUGROUP when Telnet assigns an LU from that group. A message is issued when the specified percentage is reached. After the group exceeds the specified capacity, no other message is issued. After the capacity drops below 10 percent of the capacity check amount, another capacity warning message is issued. Do not leave a blank space between the name and the comma that is part of the capacity field.

EXIT

Indicates that the *lu_group_name* value is a user-written exit routine. When the LUGROUP statement is mapped to a Client Identifier, Telnet LU assignment invokes the exit routine to select an LU name. When the LU group is defined as an LU exit, the LU names or LU ranges are optional. When the names or ranges are provided, they act as seed values for the LU exit to use however it specifies. See [“Telnet LU exit setup” on page 575](#) for exit details.

lu_name

The name of the terminal LU.

lu_name1..*lu_name2*

A range of terminal LUs.

range_rule

The wildcard method used for each character position.

Tip: When practical, define LU ranges instead of long lists of LU names. LU name assignment from an LU range is more efficient than from a long list.

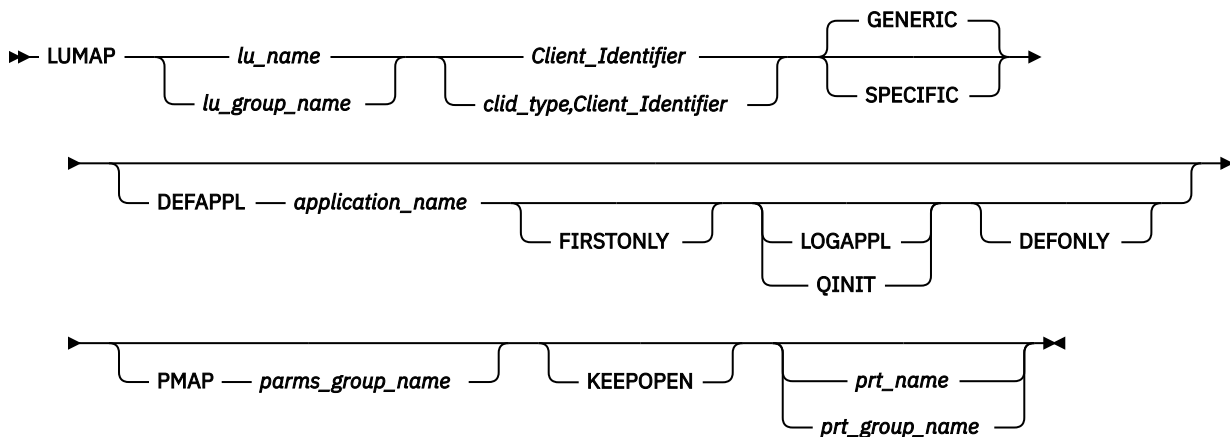

Usage notes

- See [“Rules for LU name specification”](#) on page 535 for LU name and LU Range specification rules.
- If the LU assigned to the connection is defined in LU groups mapped by both a LUG statement and an LUMAP statement, neither LU group can be defined as an LU exit.
- If a printer group is associated with the LU group on the LUMAP statement, the LU group cannot be defined as an LU exit.

LUMAP statement

Use the *optional* LUMAP mapping statement to define the mapping of an LU or group of LU objects to a Client Identifier.

Syntax

Parameters

lu_name

The name of the terminal LU.

lu_group_name

The group name that contains the terminal LUs.

clid_type

Specifies the type of Client Identifier. It is required if USERID or DESTIP are specified. See [“Rules for client identifier specification”](#) on page 537 for details.

Client_Identifier

One of several client identifiers. See [“Client identifier types and definitions”](#) on page 536 for details.

GENERIC

Indicates that the LU or LUGROUP is checked for Generic connection requests. Generic mapping statements also support Specific connection requests if there is no LU or LUGROUP mapped specifically to the client.

SPECIFIC

Indicates that the LU or LUGROUP is checked for Specific connection requests. Specific mapping statements are not used for Generic connection requests.

DEFAPPL *application_name*

Specifying DEFAPPL indicates the initial application to which Telnet connects. The *application_name* can be network qualified in the format of a 1- to 8-character name of the network separated by a period (.), followed by a 1- to 8-character application name.

FIRSTONLY

When FIRSTONLY is specified, a solicitor or USSMSG10 screen is sent to the client after logoff from a default session when LUSESSIONPEND is coded. When FIRSTONLY is not specified, Telnet always requests a new session to the default application after logoff from the session when LUSESSIONPEND is coded. If LUSESSIONPEND is not coded, the connection is dropped.

LOGAPPL

When LOGAPPL is specified, a session request to a host application that is not active is queued in VTAM instead of rejected. Telnet keeps the ACB open for the LU representing the client. When the application becomes active, VTAM initiates a session between the application and the Telnet LU.

QINIT

Indicates that session requests should be queued, and when logging off the default application, Telnet should redrive the default application instead of issuing a USSMSG10 or Solicitor screen.

DEFONLY

When DEFONLY is specified, the client is blocked from specifying any application name other than the one specified on the default application statement.

PMAP *parms_group_name*

Maps a ParmsGroup to an LU group. With this, parameters can be assigned based on the chosen LU name or group.

KEEPOPEN

Specifying KEEPOPEN means that all LUs identified in the *lu_group_name* or the LU identified by *lu_name* always have an OPEN ACB as long as the connection exists, whether or not a session exists. When KEEPOPEN is mapped to a connection, the MSG07 and LUSESSIONPEND functions are in effect whether or not they were explicitly coded.

prt_name

The name of an associated printer LU. Printer association requires a one-to-one match. A single LU name or an LUGROUP with a single LU must be specified when *prt_name* is used.

prt_group_name

The group that contains the printer LUs. Printer association requires a one-to-one match. The number of single names in the print group must equal the number of single names in the LUGROUP. The number of ranges and the number of LUs in each range must also match. The group cannot be defined as an LU exit.

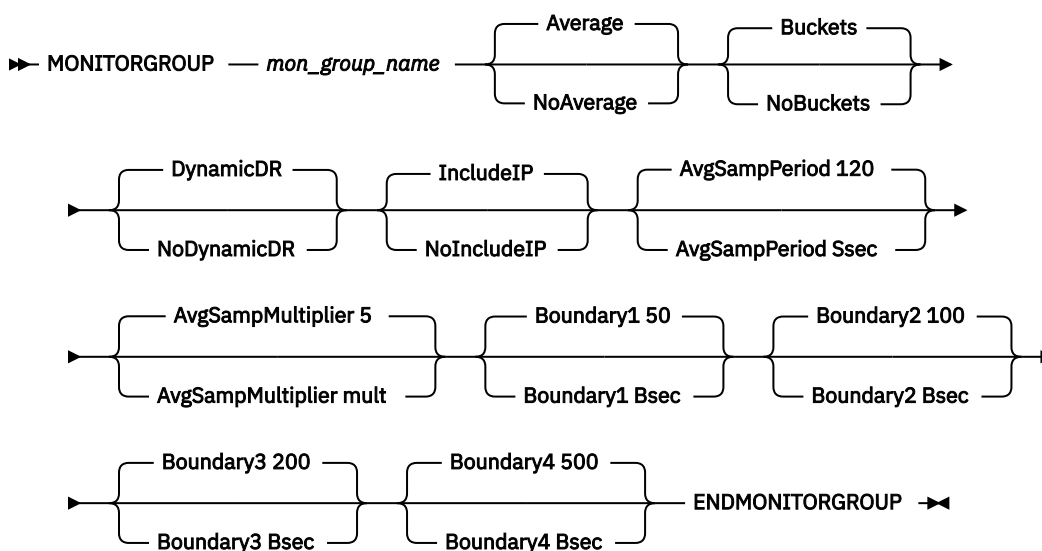

Usage notes

- A single Client Identifier can have several LU names or LU groups mapped to it. See the LU assignment information in the Telnet topic in [z/OS Communications Server: IP Configuration Guide](#) for details.
- See [“Rules for LU name specification”](#) on page 535 for LU name specification rules.

MONITORGROUP statement

Use the *optional* MONITORGROUP statement to define parameters for monitoring the performance of connections mapped to this group.

Syntax

Parameters

mon_group_name

The name of the MonitorGroup.

DynamicDR/NoDynamicDR

Indicates whether or not Telnet should add the Definite Response (DR) request to the outbound TN3270E header if it was not set on by the application. If this option is not chosen, or the client does not support DR, Telnet uses a TIMEMARK to approximate the IP transit time.

IncludeIP/NoIncludeIP

Indicates whether or not Telnet should measure the transit time on the IP side of the connection.

Average/NoAverage

Indicates whether or not sliding averages should be calculated.

AvgSampPeriod Ssec

Specifies the sampling period for a sliding-window average. Default value of 120 seconds. The valid range is 1 - 99 999 999.

AvgSampMultiplier mult

Specifies the averaging period multiplier. Default value is 5. The valid range is 0 - 99 999 999.

Buckets/NoBuckets

Indicates whether or not time buckets are being used.

Boundary1 Bsec

Defines the upper boundary time, in milliseconds, for bucket 1 that contains the number of transactions whose transit times are greater than 0 and less than or equal to boundary1. The default value is 50 milliseconds. The valid range is 0 - 99 999 999.

Boundary2 Bsec

Defines the upper boundary time, in milliseconds, for bucket 2 that contains the number of transactions whose transit times are greater than boundary1 and less than or equal to boundary2. The default value is 100 milliseconds. The valid range is 0 - 99 999 999.

Boundary3 Bsec

Defines the upper boundary time, in milliseconds, for bucket 3 that contains the number of transactions whose transit times are greater than boundary2 and less than or equal to boundary3. The default value is 200 milliseconds. The valid range is 0 - 99 999 999.

Boundary4 Bsec

Defines the upper boundary time, in milliseconds, for bucket 4 that contains the number of transactions whose transit times are greater than boundary3 and less than or equal to boundary4.

The default value is 500 milliseconds. The valid range is 0 - 99 999 999. Boundary4 also acts as the lower boundary for bucket 5, which has no upper boundary.

Usage notes

Each bucket maximum value must be higher than the preceding bucket maximum value. Zero can be specified in the first and subsequent buckets if those buckets are not wanted. After a positive value is specified, each succeeding bucket must have a higher value. A very large value, such as 99 999 990 can be used as an infinity value.

MONITORMAP statement

Use the *optional* MONITORMAP mapping statement to map a MONITORGROUP to a Client Identifier.

Syntax

Parameters

mon_group_name

The name of the MONITORGROUP.

clid_type

Specifies the type of Client Identifier. It is required if USERID or DESTIP are specified. See [“Rules for client identifier specification”](#) on page 537 for details.

Client_Identifier

One of several client identifiers. See “Client identifier types and definitions” on page 536 for details.

Usage notes

See the connection monitoring mapping information in the [z/OS Communications Server: IP Configuration Guide](#).

PARMSGROUP statement

Use the *optional* PARMSGROUP Object statement to define parameters that are mapped to a subset of all clients. The PARMSGROUP statements mapped to a client override those defined in the TELNETGLOBALS, TELNETPARMS, or BEGINVTAM block.

Syntax

Parameters

parmsgroup_name

The group name (up to eight characters) that contains the Telnet parameter statements.

valid stmts

Any Telnet statement that is permitted in PARMSGROUP. See [Table 32 on page 496](#) for a list of valid statements.

PARMSMAP statement

Use the *optional* PARMSMAP mapping statement to map a PARMSGROUP to a Client Identifier.

Syntax

Parameters

parmsgroup_name

The name of the PARMSGROUP.

clid_type

Specifies the type of Client Identifier. It is required if USERID or DESTIP are specified. See [“Rules for client identifier specification”](#) on page 537 for details.

Client_Identifier

One of several client identifiers. See [“Client identifier types and definitions”](#) on page 536 for details.

Usage notes

A single Client Identifier can have several PARMSGROUPS mapped to it. See the PARMSGROUP assignment information in the Telnet topic in [z/OS Communications Server: IP Configuration Guide](#) for details.

PORT statement

Use the *optional* PORT statement to associate the BEGINVTAM block with the correct TELNETPARMS block when multiple ports are used.

Syntax

Parameters

num

A specified port number.

,qual

Qualifies the PORT address with a destination IP address or with a specific link or interface name.

num1..num2

A consecutive range of ports starting with *num1* and ending with *num2*. *num2* must be greater than *num1*.

Usage notes

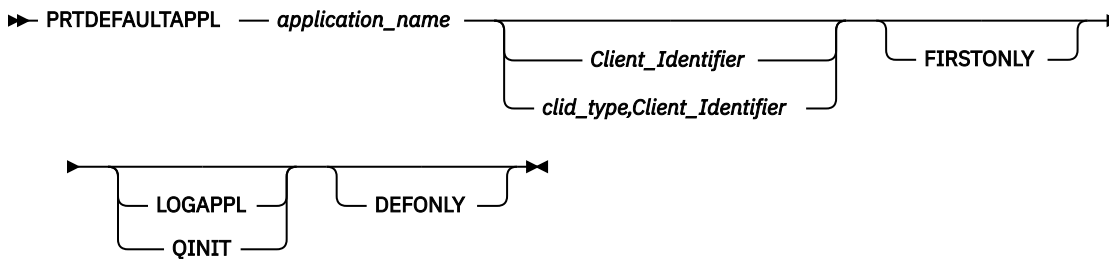

- If port,qual is coded, it must match the qualifier used in the PORT or TTLSPORT statement in the TELNETPARMS block.

- The PORT statement must be the first statement following the BEGINVTAM statement.

PRTDEFAULTAPPL statement

Use the *optional* PRTDEFAULTAPPL mapping statement to map the initial application to be tried when a Telnet client establishes a printer connection. The application can be a particular VTAM application, such as CICS.

Syntax

Parameters

application_name

The host application name, as specified in VTAMLST. The *application_name* can be network qualified in the format of a 1- to 8-character name of the network ID separated by a period (.), followed by a 1- to 8-character application name.

clid_type

Specifies the type of Client Identifier. It is required if USERID or DESTIP are specified. See [“Rules for client identifier specification”](#) on page 537 for details.

Client_Identifier

One of several Client Identifiers. See [“Client identifier types and definitions”](#) on page 536 for details. If no Client Identifier is specified, then it is considered the NULL Client Identifier.

FIRSTONLY

When FIRSTONLY is specified, the printer LU remains active with an open ACB after initial session logoff. When FIRSTONLY is not specified, Telnet always requests a new session to the default application after logoff from the session when LUSESSIONPEND is coded. If LUSESSIONPEND is not coded, the connection is dropped.

LOGAPPL

When LOGAPPL is specified, a session request to a host application that is not active is queued in VTAM instead of rejected. Telnet keeps the ACB open for the LU representing the client. When the application becomes active, VTAM initiates a session between the application and the Telnet LU.

QINIT

Indicates that session requests should be queued, and when logging off the default application, Telnet should redrive the default application instead of issuing a USSMSG10 or Solicitor screen.

DEFONLY

When DEFONLY is specified, the client is blocked from specifying any application name other than the one specified on the default application statement.

Usage notes

Always map a unique Client Identifier on each PRTDEFAULTAPPL statement. Otherwise, the last PRTDEFAULTAPPL mapping for the Client Identifier is used.

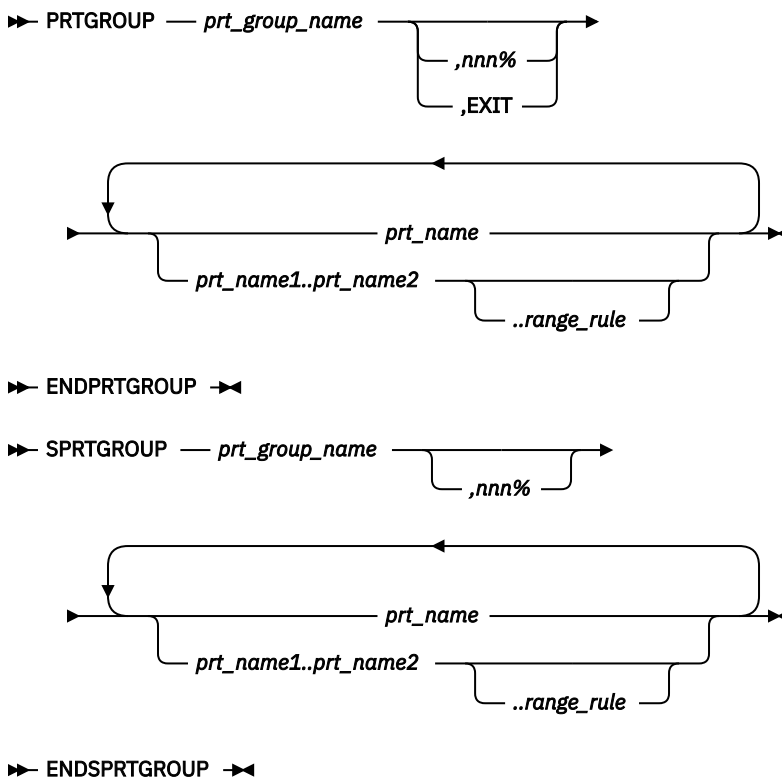

PRTGROUP or SPRTGROUP statement

Use the *optional* PRTGROUP or SPRTGROUP object statements to define a group of printer LUs. These group names can be used on the PRTMAP statement to represent a printer pool. The SPRTGROUP statement defines shared LU names rather than private ones.

Restrictions:

- This Telnet must have joined the XCF group to define shared printer LUs. An active Telnet printer LU name server (LUNS) must exist for the profile to be processed and for the shared printer LUs to be usable.
- All *prt_group_name* values on one profile must be unique, even though a profile can have both PRTGROUPs and SPRTGROUPs defined.

Syntax

Parameters

prt_group_name

The group name (1 - 8 characters in length) that contains the printer LUs.

prt_name

The name of the printer LU.

nnn%

Checks the capacity remaining in the PRTGROUP or SPRTGROUP when Telnet assigns an LU from that group. A message is issued when the specified percentage is reached. After the group exceeds the specified capacity, no other message is issued. After the capacity drops below 10 percent of the total capacity check amount, another capacity warning message is issued. Do not leave a blank space between the name and the comma that is part of the capacity field.

EXIT

Indicates that the *prt_group_name* value is a user-written exit routine. When the PRTGROUP statement is mapped to a Client Identifier, Telnet LU assignment invokes the exit routine to select an LU name. When the LU group is defined as an LU exit, the LU names or LU ranges are optional. When the names or ranges are provided, they act as seed values for the LU exit to use however it specifies. See [“Telnet LU exit setup” on page 575](#) for exit details.

prt_name1..prt_name2

A range of printer LUs.

range_rule

The wildcard method used for each character position.

Tip: When practical, define LU ranges instead of long lists of LU names. LU name assignment from an LU range is more efficient than from a long list.

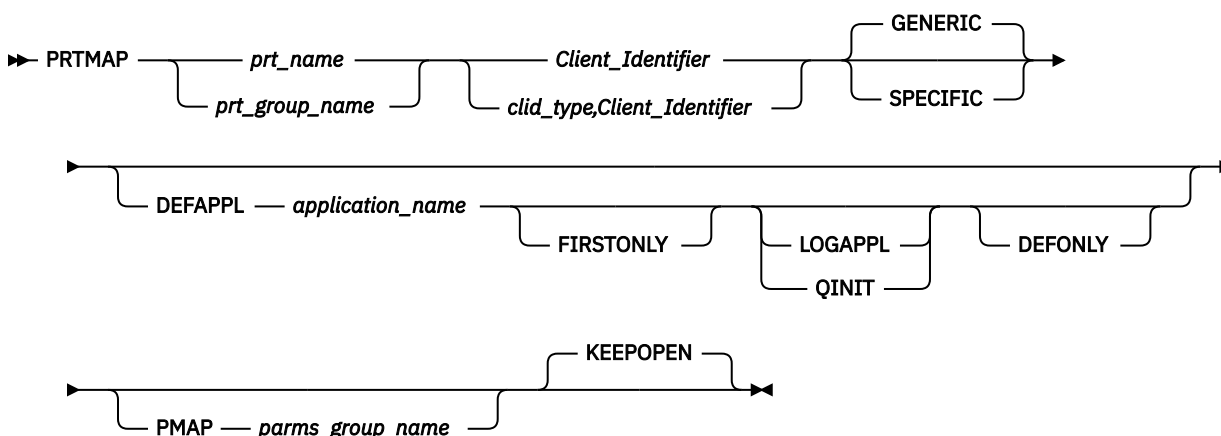

Usage notes

- See [“Rules for LU name specification” on page 535](#) for LU name and LU range specification rules.
- If the LU assigned to the connection is defined in LU groups mapped by both a LUG statement and an PRTMAP statement, neither LU group can be defined as an LU exit.
- If the printer LU group is used as an associated printer group on an LUMAP statement, the group cannot be defined as an LU exit.

PRTMAP statement

Use the *optional* PRTMAP mapping statement to define the mapping of a printer LU or group of printer LUs objects to a client identifier.

Syntax

Parameters

prt_name

The name of the printer LU.

prt_group_name

The group name that contains the printer LUs.

clid_type

Specifies the type of Client Identifier. It is required if USERID or DESTIP are specified. See [“Rules for client identifier specification” on page 537](#) for details.

Client_Identifier

One of several client identifiers. See [“Client identifier types and definitions”](#) on page 536 for details.

GENERIC

Indicates that the LU or PRTGROUP are checked for Generic connection requests. Generic mapping statements also support Specific connection requests if there is no LU or PRTGROUP mapped specifically to the client.

SPECIFIC

Indicates that the LU or PRTGROUP are checked for Specific connection requests. Specific mapping statements are not used for Generic connection requests.

DEFAPPL *application_name*

Specifying DEFAPPL indicates the initial application to which Telnet connects. The *application_name* can be network qualified in the format of a 1- to 8-character name of the network separated by a period (.), followed by a 1- to 8-character application name.

FIRSTONLY

When FIRSTONLY is specified, the printer LU remains active with an open ACB after initial session logoff from the default session. When FIRSTONLY is not specified, Telnet always requests a new session to the default application after logoff from the session when LUSESSIONPEND is coded. If LUSESSIONPEND is not coded, the connection is dropped.

LOGAPPL

When LOGAPPL is specified, a session request to a host application that is not active is queued in VTAM instead of rejected. Telnet keeps the ACB open for the LU representing the client. When the application becomes active, VTAM initiates a session between the application and the Telnet LU.

QINIT

Indicates that session requests should be queued, and when logging off the default application, Telnet should redrive the default application instead of issuing a USSMSG10 or Solicitor screen.

DEFONLY

When DEFONLY is specified, the client is blocked from specifying any application name other than the one specified on the default application statement.

PMAP *parms_group_name*

Maps a ParmsGroup to an LU group. With this, parameters can be assigned based on the chosen LU name or group.

KEEPOPEN

Specifying KEEPOPEN means that all LUs identified in the *lu_group_name* or the LU identified by *lu_name* always have an OPEN ACB as long as the connection exists, whether or not a session exists. For printers, this option is always set. When KEEPOPEN is mapped to a connection, the MSG07 and LUSESSIONPEND functions are in effect whether or not they were explicitly coded.

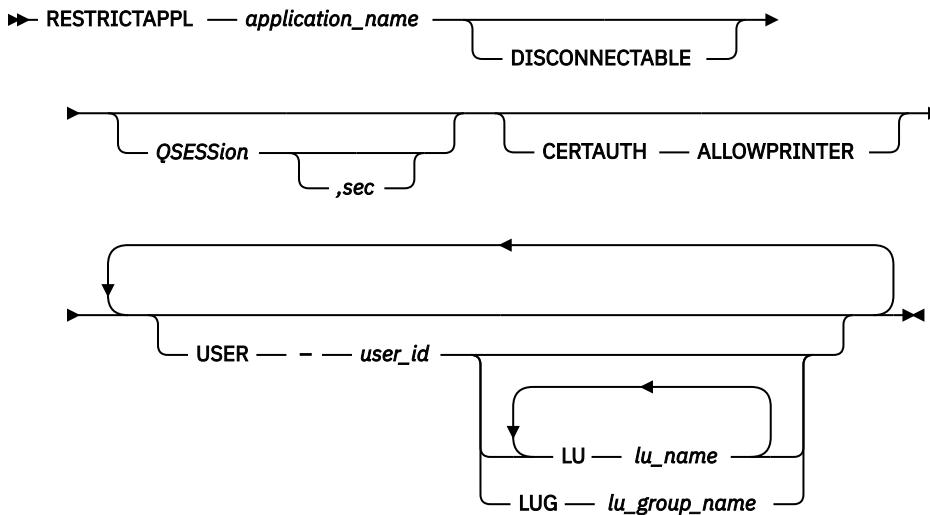

Usage notes

- A single Client Identifier can have several printer LU names or printer LU groups mapped to it. See the LU assignment information in the Telnet topic of the [z/OS Communications Server: IP Configuration Guide](#).
- See [“Rules for LU name specification”](#) on page 535 for LU name specification rules.

RESTRICTAPPL statement

Use the *optional* RESTRICTAPPL mapping and security statement to restrict access to the specified application. This statement should be followed by user parameters defining each user who is authorized to use the application. Users are prompted to identify themselves with a password. RACF or an equivalent security program is used to validate the password. If no user parameters are specified, the application cannot be accessed.

Syntax

Parameters

application_name

The host application name, as specified in VTAMLST.

Single-character position wildcards (%) are permitted anywhere in the application name and the multi-character wildcard (*) is permitted at the end of an application name. For example, A%CICS* restricts connections to A1CICS01, A1CICS02, ABCICS4A, and so on. A single * restricts all applications.

DISCONNECTABLE

When DISCONNECTABLE is specified, VTAM notifies the application to disconnect, rather than log off a user, when the session is dropped.

QSESSIon

Indicates this application queues a session request when passing the session to another primary application. When Telnet receives an UNBIND of the new session, Telnet waits for a BIND to reestablish the original queued session.

sec

When QSESSIon is coded, this value determines the number of seconds Telnet waits before checking whether a BIND was received. The range is 1 - 99999999. If no BIND is received in the time specified, Telnet stops waiting and continues cleaning up the connection as if QSESSIon had not been coded. There is no default value. If sec is not coded, the connection never checks whether a BIND is received. Telnet waits until a BIND is received or the connection is dropped.

CERTAUTH

Specifies to use the derived User ID based on the SSL Client Certificate (enhanced LU mapping support for dynamic IP environments) and skips the Restrictappl password validation process. If Express Logon is being used, the User ID returned from security lookup for the latest Client Certificate/Applid combination is used. If not using Express Logon, the User ID returned at initial connection time from security lookup for just the Client Certificate is used.

ALLOWPRINTER

Specifies that any printer connection matching this RESTRICTAPPL statement is treated as if it matched an ALLOWAPPL statement. No user ID or password is requested. Printer emulators do not support user ID and password requests. The ALLOWPRINTER parameter gives you the ability to have terminal connections and printer connections mapped on a single RESTRICTAPPL statement. However, the printer connections exist at the lower security level that is provided by the ALLOWAPPL statement.

USER *user_id*

The user ID, one to eight characters long. Single-character wildcards (%) are permitted anywhere in the user name and the multi-character wildcard (*) is permitted at the end of the user name. A single * allows all users.

LU *LU_name*

The logical name of the Telnet terminal LU. This parameter allows you to optionally specify which terminal LUs can be used to establish a session with the named VTAM host application.

LUG *LU_group_name*

The name of an LUGROUP or PRTGROUP. This option allows you to specify an LUGROUP or PRTGROUP, where any LU in the group can be used to establish a session with the named VTAM host application. If the same name defines both an LUGROUP and a PRTGROUP, the LUGROUP is used. The group can be a new group consisting of a combination of names or range list names from existing LUGROUPs and PRTGROUPs. This allows both terminals and printers to be on the same RESTRICTAPPL-USER statement.

Usage notes

- LU and LUG keywords are mutually exclusive. If both are specified in any order, only the LUG is processed. If multiple LUG keywords are specified, only the last is accepted and processed.
- Applications that do CLSDST Pass also require a RESTRICTAPPL or ALLOWAPPL statement for the target application.
- If the LU assigned to the connection is defined in LU groups mapped by both a LUG statement and an LUMAP/PRTMAP statement, neither LU group can be defined as an LU exit.

USERGROUP statement

Use the *optional* USERGROUP object statement to define a group of user IDs. The group name can be used on several mapping statements.

Syntax**Parameters*****user_group_name***

The group name (up to 16 characters) that contains user ID names which represent clients when the client certificate is translated into a user ID.

user_IDs

An exact user ID name or a wildcard user ID name.

User ID names can be wildcarded when specified in a group.

- % or ? is a single character position wildcard. It can be placed anywhere.
- * is a multi-position wildcard. It can only be placed at the end of the user ID.
- The two wildcard types can be used together. For example, U%%V5* is a valid wildcard name.

The position of the single wildcard (%) is used first to determine the most specific match. For example, the following wildcard names are checked in the order listed:

- M5MUSER*
- M5M%%%%*
- M5%USER*

- M%MUSER*
- M%MUS%R*
- M%MUS%*
- M%MU%ER*
- M*

USSTCP statement

Use the *optional* USSTCP mapping statement to map a customized USS table to a Client Identifier. You can use an existing table or create a USS table, assemble it, and load it into your system library.

Syntax

Parameters

3270_table_name

The name of the 3270 format USS table load module.

scs_table_name

The name of the SCS format USS table load module.

clid_type

Specifies the type of Client Identifier. It is required if USERID or DESTIP are specified. See [“Rules for client identifier specification”](#) on page 537 for details.

Client_Identifier

One of several client identifiers. See [“Client identifier types and definitions”](#) on page 536 for details. If no Client Identifier is specified, then it is considered the NULL Client Identifier.

Usage notes

- An assembled USS table load module from VTAM can be used or one can be created. For coding details, see [z/OS Communications Server: IP Configuration Guide](#). Also see [“Telnet USS table setup”](#) on page 561.
- Always map a unique Client Identifier on each USSTCP statement. Otherwise, the last USS table mapping for the Client Identifier is used.
- The most common setup error is to fail to include the table load module in a load library accessible by TCP/IP.
- If a default application and a USS table are both mapped to the same Client Identifier, the default application is used. The USS messages are used in case of an error or if FIRSTONLY is specified on DEFAULTAPPL.
- If an SCS format USS table is specified, it is used for all TN3270E connections. Non-TN3270E connections continue to use the 3270 format USS table. If no SCS format USS table is specified, all connections use the 3270 format USS table. In this case, a BIND/UNBIND is sent to the TN3270E client before/after USS processing.

Telnet USS table setup

This topic includes information about the Telnet USS table setup, including general rules and macroinstructions.

USSCMD

The USSCMD macroinstruction is used to define Telnet terminal operator commands.

USSMSG

The USSMSG macroinstruction defines Telnet terminal operator messages (USSMSGxx).

USSPARM

The USSPARM macroinstruction defines an operand or positional parameter that can be specified on a command identified by the USSCMD macroinstruction. It also defines default values for the operand or positional parameter.

There can be multiple USSPARM macroinstructions associated with a USSCMD macroinstruction. For each operand (keyword or positional), code a USSPARM macroinstruction.

USSEND

The USSEND macroinstruction delimits the end of the USS table.

USSTAB

The USSTAB macroinstruction indicates the beginning of a USS table.

General usage rules for Telnet USS macroinstructions

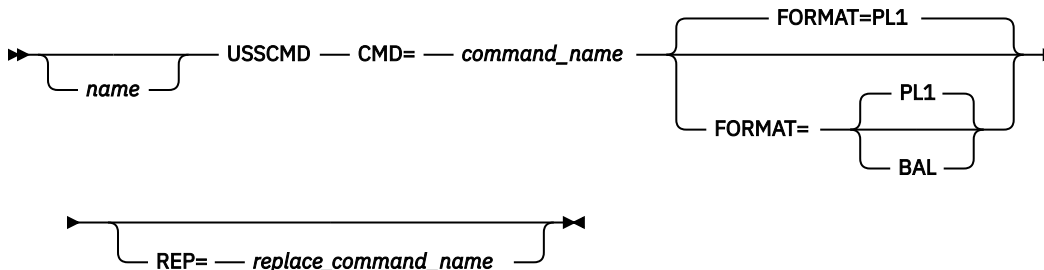

Observe the following general usage rules for Telnet USS macroinstructions:

- The Telnet USS macroinstructions can be coded exactly as the VTAM macroinstructions. A few VTAM parameters are not supported by Telnet. In these cases, the parameter value is ignored and does not interfere with the execution of the macroinstruction. Differences between Telnet and VTAM are listed under usage notes for each macroinstruction.
- An assembled and linked VTAM USS table can be used directly by Telnet. Unsupported statements are ignored and do not interfere with the processing of the command.
- For additional information about installing or changing an interpret table, See the [z/OS Communications Server: SNA Resource Definition Reference](#), which contains instructions for using the Telnet solicitor or USS Logon Panel.
- A sample USS table is located in SEZAINST(EZBTPUST).
- The USS Macroinstructions can be found in *hlq.SISTMAC1*, the VTAM macro library.

USSCMD macroinstruction

Use the USSCMD macroinstruction to define a Telnet operator or terminal operator command.

Syntax

Parameters

name

Specifies the name assigned to the macroinstruction.

CMD=command_name

Specifies the command name assigned to the macroinstruction.

FORMAT=BAL

Specifies the user-defined command indicated on this USSCMD macroinstruction in Basic Assembler Language (BAL) syntax.

command

Identifies the command. It is followed by one or more blanks.

p

Specifies one or more positional operands. Positional operands are entered in the format Pn , where n is the position number of the operand. Each operand (unless it is the last in the command) is followed by a comma. Positional operands must appear before any keyword operands.

keyword

Specifies keyword operand associated with the command. Each operand (unless it is the last in a command) is followed by a comma.

value

Determines the value assigned to a keyword operand.

FORMAT=PL1

Specifies the user-defined command specified on this USSCMD macroinstruction in PL/I programming syntax.

command

Identifies the command. It is followed by one or more blanks or by a left parenthesis (that is, positional operands).

p

Specifies one or more positional operands. Positional operands are entered in the format Pn , where n is the position number. If positional operands are used, the parentheses must be coded.

keyword

Used to enter each operand parameter. Each operand must be followed by one or more blanks or by a value enclosed in parentheses.

value

The value assigned to a keyword operand.

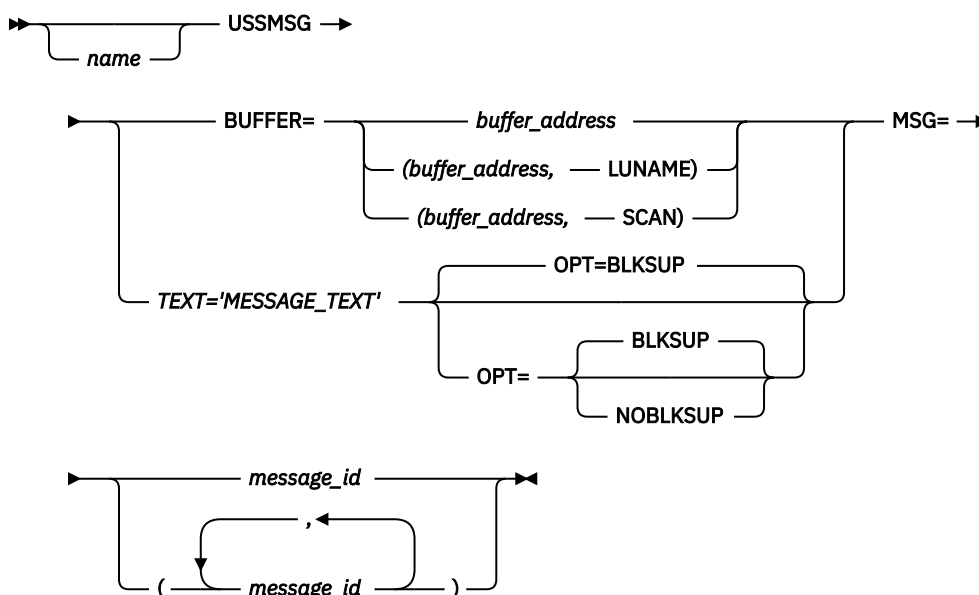

REP=replace_command_name

Specifies the valid command that is to replace the user-defined command indicated by the CMD operand. If the REP operand is not coded, the value specified in the CMD operator is used.

USSMSG macroinstruction

Use the USSMSG macroinstruction to define Telnet terminal operator messages (USSMSGxx).

Syntax

Parameters

name

Specifies the name assigned to the macroinstruction.

buffer_address

Specifies the address (name) of an area of storage defined to contain the message text and a header indicating the length of the message text. The storage area must be formatted as shown in [Figure 20](#) on page 564.

Figure 20. USS message layout in storage

The message text defined in the storage area must follow the USSEND macroinstruction.

The message text is sent to the terminal operator as it appears in the storage area. Telnet does not modify or translate the message text. You are responsible for including any device-dependent control characters within the message. The data format must be 3270 data stream or SNA character stream (SCS). Both are not supported by Telnet.

LUNAME|SCAN

Specifies that the character strings listed in [Table 37 on page 565](#) are replaced with the appropriate values in the position in the message where the character string occurred. The entire string specified by BUFFER is searched, using the character @. System symbolics are also replaced with their appropriate value. When using the system symbolics in the USS table, an extra ampersand (&) must be prepended to the system symbolic for the assembler compiler to create the correct output. For example, system symbolic &sysname. must be in the table as '&&sysname.' for the compiled output to be '&sysname.'

Table 37. Variables substituted for USSMSG

Character string	Message text	Format
@@@@DATE	Current Date	8 bytes, in the format specified by the DATEFRM and DATEDLM operands on the USSTAB macroinstruction.
@@@@@@@IPADDR @..@IPADDR(1)	Client IP Address	15 bytes, leading 0's suppressed, left-aligned, with trailing blanks if needed.
@...@IPHOSTNAME (2)	Client host name	40 bytes, name left-aligned with trailing blanks if needed.
@@LUNAME (3)	Client LU Name (SLU)	8 bytes, name left-aligned with trailing blanks if needed.
@@PRT	Client Port Address	5 bytes and leading 0's are not suppressed.
@@@@RUNAME	Failing operation Name	10 bytes, name left-aligned with trailing blanks if needed.
@@@SENSE	Sense Code or Return Code	8 bytes.
@@@@TIME	Current Time	8 bytes in the HH_MM_SS format, where an underscore (_) is the delimiter specified on the TIMEDLM operand of the USSTAB macroinstruction.
@HOSTNET @@@NETID @...@NQN (4) @@SSCPNM @@@@@@@ZONEID		Placeholders for Telnet. Accepted for use, but are set to blanks.

Notes:

1. IPv6 IPADDR must be preceded by 33 @ symbols.
2. IPHOSTNAME must be preceded by 30 @ symbols.
3. @@LUNAME is substituted when it is known. For TN3270 connections, the LU name is not known until after the MSG10 screen is sent to the end-user because the application name is not yet known.
4. NQN must be preceded by 14 @ symbols.

message_id

Specifies which message or messages are defined by this macroinstruction. [Table 38 on page 566](#) shows the default table variable substitution and examples.

For terminal operator messages, enter decimal integers in the range 0 - 14. The numbers 0 - 14 correspond to the USS messages with message IDs of USSMSG00 through USSMSG14, respectively.

Restriction: USSMSG00 is not defined in the IBM-supplied USS table. If you do not define this message, no message is sent in this case.

<i>Table 38. Default table variable substitution</i>		
Message	Variable	Example
MSG00	Command	% COMMAND ACCEPTED
MSG01	Command	INVALID % COMMAND SYNTAX
MSG02	Command	% COMMAND UNRECOGNIZED
MSG03	Command parameter	% PARAMETER EXTRANEIOUS
MSG04	<ul style="list-style-type: none"> Command parameter Command parameter value 	% PARAMETER VALUE %(2) NOT VALID
MSG05	None	UNSUPPORTED FUNCTION
MSG06	Message not used	Not applicable — NOT USED BY TELNET
MSG07	<ul style="list-style-type: none"> LU name Operation that failed Sense Code 3 or Return Code. See message EZZ6035I for return code explanation. 	%(1) UNABLE TO ESTABLISH SESSION — %(2) FAILED WITH SENSE %(3)
MSG08	None	INSUFFICIENT STORAGE
MSG09	Message not used	Not applicable — NOT USED BY TELNET
MSG10	None	A 3270 data format screen
MSG11	Message not used	Not applicable — NOT USED BY TELNET
MSG12	None	REQUIRED PARAMETER OMITTED
MSG13	Text after IBMTEST echoed back	IBMECHO %
MSG14	Message number that could not be displayed	USS MESSAGE % NOT DEFINED

OPT=BLKSUP|NOBLKSUP

BLKSUP specifies that extraneous blanks are suppressed from the message. Any sequence of two or more blanks is converted into a single blank. NOBLKSUP specifies that extraneous blanks are not suppressed from the message. Any sequence of two or more blanks is presented unchanged in the message.

message_text

Specifies the text to use in the USS messages identified by the MSG operand. Within *message_text*, place any combination of the character strings described in [Table 37 on page 565](#). Telnet places the strings with the values shown in the table.

Rule: Blank suppression always occurs, even if OPT=NOBLKSUP is coded.

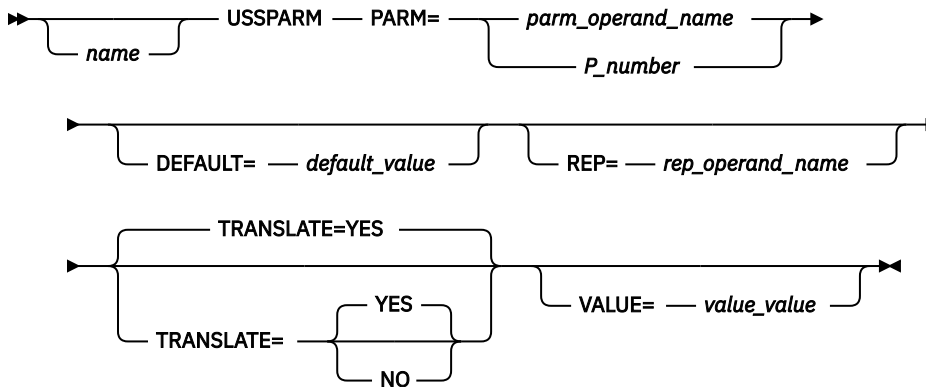

Usage notes

For TN3270E, this limitation exists. Unless specific IP-to-LU mapping is used, the LU name is not known for non-TN3270E sessions until an application is chosen from the MSG10 screen. Therefore, no @@LUNAME substitution takes place on the MSG10 screen for non-TN3270E sessions.

USSPARM macroinstruction

Use the USSPARM macroinstruction to define an operand or positional parameter that can be specified on a command identified by the USSCMD macroinstruction. It also defines values for the operand or positional parameter. There can be multiple USSPARM macroinstructions associated with a USSCMD macroinstruction. For each operand (keyword and positional), code a USSPARM macroinstruction.

Syntax

Parameters

name

Specifies the name assigned to the macroinstruction.

parm_operand_name

Specifies the keyword parameter in the user-entered command to which this USSPARM macroinstruction applies. *parm_operand_name* must be 1–8 alphanumeric characters.

P_number

Specifies a positional parameter, where *number* is a decimal integer from 1 to the maximum number of positional parameters for the command. *P_number* indicates the positional parameter in the user-entered command to which this USSPARM macroinstruction applies.

default_value

Specifies a default value to be used if the operand is omitted when the command is entered. If DEFAULT is not specified, the operand is treated as if it were not entered.

If the parameter in the PARM operand allows a network-qualified name to be specified, then the value of DEFAULT can be a network-qualified name.

rep_operand_name

Specifies the parameter is replaced with *rep_operand_name*. The value for *rep_operand_name* must be 1–8 alphanumeric characters. The value of the operand is assigned from the parameter specified by PARM. If PARM specifies a keyword parameter, its value is assigned to the operand specified by REP. If PARM specifies a positional parameter, its value is treated as if it were an operand value and it is assigned to the operand specified by REP.

If REP is not coded, it takes the value of PARM. (That is, the user-entered parameter is used as entered.)

Positional parameters such as P1 and P2 can also be used as operands.

TRANSLATE=YES|NO

Controls translation of the specified USSPARM.

TRANSLATE=YES is the default and specifies that the USSPARM is translated using the translation table associated with the USS table this USSPARM is coded in, unless the character string is within single quotation marks. Character strings within single quotation marks are not translated.

TRANSLATE=NO specifies that the USSPARM is not translated. TRANSLATE=NO is intended to be coded only on the USSPARM for DATA when the data contains a mixed-case password and the destination application supports mixed-case passwords. For more information about [mixed-case passwords](#), see [z/OS Communications Server: IP Configuration Guide](#).

value_value

Specifies the default value to be used if the operand specified by the PARM operand is entered without a value.

VALUE is in contrast with the DEFAULT operand, which specifies the default to be used if the operand itself is not entered.

If multiple VALUE operands are specified for the same operand, the first VALUE operand is used.

If the parameter in the PARM operand allows a network-qualified name to be specified, then the value of VALUE can be a network-qualified name.

Examples

The following code is an example using TRANSLATE=NO to bypass the translation table and pass a mixed case user ID and password, assuming the translation table is used to convert all text to upper case.

```
AUSSTAB  USSTAB
APPL1    USSCMD  CMD=APPL1,REP=LOGON,FORMAT=PL1
          USSPARM PARM=APPLID,REP=APPLID,DEFAULT=APPL1
          USSPARM PARM=P1,REP=DATA,TRANSLATE=NO
          USSPARM PARM=P2,REP=LOGMODE
          USSEND
```

The following terminal operator command is entered:

```
appl1 user1/PaSsWrD1 interact
```

The command sends DATA() and a LOGMODE() to application APPL1. The LOGMODE value is translated to upper case. No character translation was performed on user1/PaSsWrD1 because TRANSLATE=NO was coded on the DATA USSPARM. The application receives a logmode value of INTERACT and data value of user1/PaSsWrD1.

Usage notes

- The DEFAULT and VALUE operands cannot be coded on the same USSPARM macroinstruction. To use both operands, code two USSPARM macroinstructions with the same value specified for PARM. The macroinstruction specifying VALUE must precede the one containing the DEFAULT operand. If REP is to be specified, it must be on the macroinstruction containing the VALUE operand. For example,

```
USSPARM P=T,REP=TYPE,VALUE=COND
USSPARM P=T,REP=TYPE,DEFAULT=COND
```

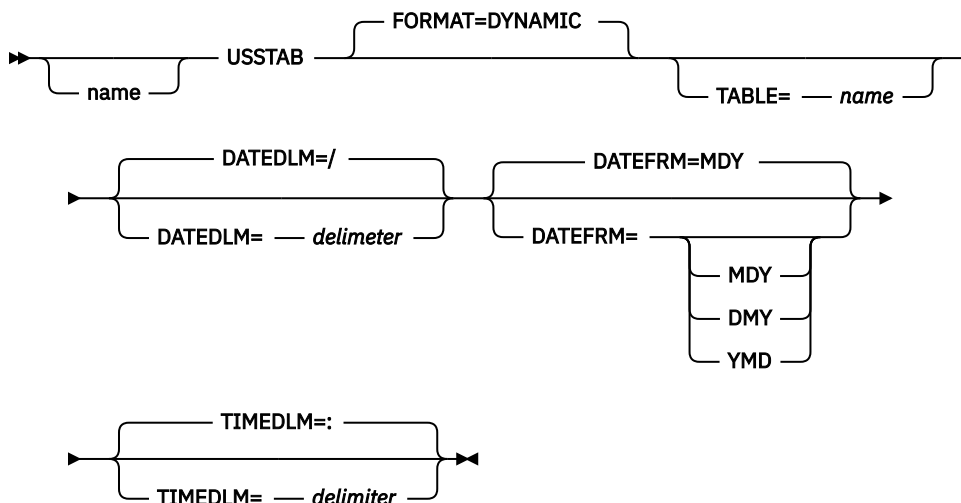

- For multiple specifications of the same parameter, the last value specified is used. An exception is if positional parameters are used to represent the DATA parameter. Specifying multiple data positional parameters permits a data string with a blank to be entered. Each blank acts as a parameter delimiter. If the number of blanks is known, multiple DATA parameters can be used instead of using an interpret table. For example, a LOGON TSO command can have two DATA parameters. The first could be USERID and the second could be the PROC. Telnet accepts both parameters and passes both as data to the host application with a blank between the parameters.
- Parameters used by Telnet are:

```
LOGON APPLID,LOGMODE,DATA
LOGOFF
IBMTTEST # of retries
```

USSTAB macroinstruction

Use the USSTAB macroinstruction to indicate the beginning of a USS table.

Syntax

Parameters

name

Specifies the required CSECT name for the USS table.

FORMAT= DYNAMIC

Specifies how the USS table is formatted. Dynamic is required for Telnet.

TABLE=name

Specifies the translation table that is used by Telnet to translate character-coded commands. If a translation table is coded in the specified USS table, the table that is used. If no table is coded, the table in the IBM default EZBTPOST is used. If EZBTPOST has been altered and no longer contains a translation table, an internal translation table is used that is the same as the table in EZBTPOST.

DATEDLM

Specifies the character to be used as a delimiter to separate the month, day, and year parts of the date where @@@@DATE is specified in the message text. The slash (/) is used if DATEDLM is not specified. An ampersand (&) and single quotation mark (') are not valid delimiters.

DATEFRM

Specifies the date format to be used where @@@@DATE is specified in the message text. Note that the delimiter used between the month, day, and year is specified on the DATEDLM operand.

DMY

Specifies the day, followed by month, followed by year as dd_mm_yy, where an underscore (_) is the delimiter specified on the DATEDLM operand.

MDY

Specifies the month, followed by day, followed by year as mm_dd_yy, where an underscore (_) is the delimiter specified on the DATEDLM operand.

YMD

Specifies the year, followed by month, followed by day as yy_mm_dd, where an underscore (_) is the delimiter specified on the DATEDLM operand.

TIMEDLM

Specifies the character to be used as a delimiter to separate the hour, minutes, and seconds parts of the time where @@@@TIME is specified in the message text. The colon (:) is used if TIMEDLM is not specified. An ampersand (&) and single quotation mark (') are not valid delimiters.

USSEND macroinstruction

Use the USSEND macroinstruction to delimit the end of a USS table.

Syntax

```

→ [ name ] USSEND →

```

Parameters***name***

Specifies the name assigned to the macroinstruction.

Telnet INTERPRET table setup

This topic includes information about the Telnet INTERPRET table setup, including general rules and macroinstructions.

INTAB

The INTAB macroinstruction defines an interpret table that lists the Telnet application programs with which one or more logical units can establish a session. One INTAB macroinstruction defines the name of the interpret table and a group of logon messages definitions.

LOGCHAR

The LOGCHAR (logon-characters) macroinstruction defines a single logon message and the name of a host application program. More than one LOGCHAR can be included in an interpret table.

General usage rules for Telnet INTERPRET macroinstructions

Observe the following general usage rules for Telnet INTERPRET macroinstructions

- The Telnet interpret macroinstructions can be coded exactly as the VTAM macroinstructions. Telnet supports all functions supported by VTAM.
- An assembled and linked VTAM interpret table can be used directly by Telnet.
- For additional information about installing or changing an interpret table, see [z/OS Communications Server: SNA Resource Definition Reference](#), which contains instructions for using the Telnet solicitor or USS Logon Panel.
- A sample interpret table is located in SEZAINST(EZBTPINT).
- The INTERPRET macros can be found in *hlq*.SISTMAC1, the VTAM macro library.

INTAB macroinstruction

Use the INTAB macroinstruction to define an interpret table that lists the VTAM application programs with which one or more logical units can establish a session. One INTAB macroinstruction defines the name of the interpret table and a group of logon message definitions.

Syntax

Parameters

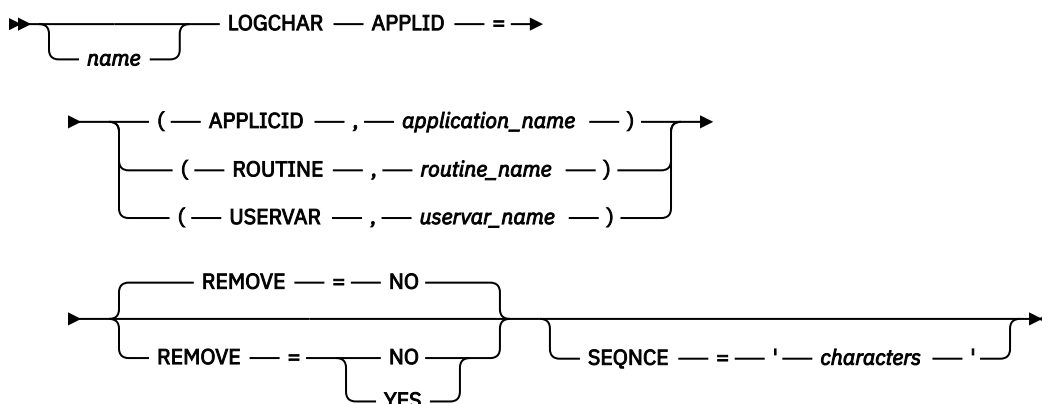

name

Specifies an optional name for the macroinstruction. If specified, *name* must be unique and should be used as the operand for the assembler language END statement. When the macroinstruction is assembled, this name is used to identify the entry point to the interpret table CSECT.

LOGCHAR macroinstruction

Each LOGCHAR (logon-characters) macroinstruction defines a single logon message and the name of an application program, a logon interpret routing, or a USERVAR. You can include more than one LOGCHAR macroinstruction in an interpret table.

Syntax

Parameters

name

Specifies an optional name on the macroinstruction. This name is not used by Telnet and is ignored.

APPLID

Specifies the name of an application program, a logon interpret routine, or a USERVAR.

(APPLICID,application_name)

Specifies the name of the application program. *application_name* can be any of the following values:

- ACBNAME of an application program in this host
- *applname* of an application program in this host
- *applname* of an application program in another host
- USERVAR representing an application program

application_name can be a network-qualified name. A network-qualified name takes the form of *netid.application_name*. If *application_name* is network-qualified, the network identifier is considered real and is not allowed to change. The resource name of the network-qualified name is considered Generic and can undergo USERVAR translation.

Restriction: If ACBNAME and the network name on the APPL definition statement for the application program are different, you cannot use a network-qualified ACBNAME.

(ROUTINE,routine_name)

Specifies the routine name of the associated logon-interpret routine. All logon-interpret routines specified in an interpret table must be assembled and link-edited with that interpret table.

(USERVAR,user_var_name)

The same as specifying APPLICID.

REMOVE=YES

Specifies that Telnet is to remove the first nonblank set of characters from the user logon sequence data being processed. The remaining data is left-aligned and padded with blanks on the right. The one exception to the padding rule is when there are no nonblank characters remaining after the removal is done, in which case nothing is passed in the user data field of the CINIT. You can substitute Y for YES when coding this parameter.

REMOVE=NO

Specifies that Telnet is not to remove any data from the user logon sequence. You can substitute N for NO when coding this parameter.

For example, if the following information is sent and REMOVE=Y is specified, Telnet removes "IMS10" before it passes the information to the application program in the user data field of the CINIT RU.

```
IMS10 NAME PASSWORD =====> NAME PASSWORD
```

SEQNCE

Specifies the required part of a logical unit's logon message.

The logon message might have additional data beyond the characters specified in the LOGCHAR macroinstruction. That data can be used and possibly changed by the logon-interpret routine if the ROUTINE operand is specified. Whether or not the data is changed or if a routine is called at all, the data is passed to the application program as user data.

To specify an apostrophe (') or an ampersand (&) within the logon message, code a double apostrophe (") or a double ampersand (&&) within the character string. If the terminal user enters the logon message in lowercase and the message is not translated to uppercase (for example, by USS translate table), the value for '*characters*' must be coded in lowercase.

Do not specify leading and trailing device-control characters within a character string that is to be interpreted, because the USS facility deletes these characters. Device control characters coded within a logon message are deleted; therefore, a blank should not be coded for each occurrence of these characters. However, if a character within the logon message is translated to a blank by the interpret table, code a blank to represent that character.

LOGCHAR without SEQNCE or with SEQNCE='*' is considered a default match to the logon message. Telnet accepts the logon message and requests logon to the application program specified in the LOGCHAR macroinstruction. Therefore, place a default match LOGCHAR macroinstruction at the end of the interpret table. Otherwise, the remaining logon messages in the interpret table are not compared with the logon message entered by the terminal user.

Guideline: If you use two or more LOGCHAR macroinstructions, arrange them so that their SEQNCE fields are in reverse collating order.

Usage notes

- Telnet compares the logon message (character by character) with successive entries in the specified interpret table. If the leading characters in the logon message correspond to all the characters in an entry in the interpret table, Telnet accepts the logon message as valid (even though the logon message can be longer than the corresponding entry in the interpret table). If the first character or characters of several logon messages are identical, you should arrange the LOGCHAR macroinstructions so the logon sequences for the logon messages are from the most restrictive (greatest number of characters) to the least restrictive (fewest number of characters). For example:

```
SEQ1 LOGCHAR APPLID=(APPLICID,AP2),SEQNCE='LOG2'
SEQ2 LOGCHAR APPLID=(APPLICID,AP1),SEQNCE='LOG'
```

- Otherwise, in the preceding example, if sequence LOG had preceded LOG2 in the interpret table, both logon messages LOG and LOG2 would be valid logons to application program AP1. If you use two or more LOGCHAR macroinstructions, they must be arranged so that their SEQNCE fields are in reverse collating order.

Coding LOGON-INTERPRET routines

You can code logon-interpret routines to validate logons and determine the name of the application program that is to receive the logons. The entry point name must match the *routine name* specified in the APPLID=(ROUTINE,*routine name*) operand in the LOGCHAR macroinstruction. All logon-interpret routines specified in an interpret table must be assembled and link-edited with that interpret table.

The logon-interpret routine interface allows the routine to supply a network-qualified application name for interpreted logons.

If you want the logon-interpret routine to supply a network-qualified application name, you need to change the interpret routine parameter list. If you do not want the routine to supply a network-qualified name, you do not need to change the routine parameter list. You can use Registers 0 and 1 to supply the application name.

Requirements for logon-interpret routines

Entry from:

Telnet

Entry point:

routine name

Contents of registers at entry:

Register 0:

Length of logon message (any length from 1 to 80)

Register 1:

Address of first byte of logon message. For LOGON requests, Telnet searches the interpret table again, after USS translation, looking only for the specified APPLID. After USS translation, register 1 contains the address of the first byte of the APPLID.

Register 2:

Address of an 8-byte logical unit name

Register 4:

Address of parameter list for the network identifier and resource name.

Register 13:

Address of a 72-byte save area provided by Telnet.

Register 14:

Return address

Register 15:

Address of entry point of this routine.

Contents of Registers at Exit: If the interpreted name in the parameter list is blank, Registers 0 and 1 contain the name of the VTAM application program (in EBCDIC characters) with which Telnet is to establish a session:

Register 0:

First 4 characters of name (left-aligned).

Register 1:

Last 4 characters of name (left-aligned).

Registers 2–14:

Restored to condition at entry.

Register 15:

Return code:

00

Application program was found and the name is placed in registers 0 and 1.

Non0

Application program was not found and the name is not placed in registers 0 and 1.

If the name of the application program contains fewer than 8 characters, use blanks to provide a name with 8 characters.

Logon-interpret routine parameter list

When the exit gets control, the address of the following parameter list is in register 4. Offsets 0 through 27 include information about the fixed or interpreted name. Offset 28 includes the uninterpreted name.

Table 39. Logon interpret routine parameter list			
Dec offset	Size (bytes)	Description	Input or output
0	2	Length of parameter list	Input
2	8	Name of requesting LU	Input
10	17	Interpreted name (in the form or either name or netid.name)	Output
27	1	Length of uninterpreted name	Input
28	n	Uninterpreted name	Input

Operation: The logon-interpret routine is run synchronously in pageable storage under the control of Telnet and not under the control of an application program. For the application program to receive the logon, this routine must validate the logon, obtain the name of the application program to receive control, and provide this name back to Telnet. Otherwise, the routine specifies that the logon is not valid or that the name of the application program was not found in Telnet.

The logon-interpret routine must also:

- Save and restore the contents of registers 2–14 when receiving and passing control.
- Use re-enterable code (the routine must not store anything within itself or modify itself during execution).
- Perform no I/O operations; an I/O request causes the routine to terminate abnormally.

The routine gets control in supervisor state with a Telnet storage key, so errors within the routine could cause damage to Telnet or to system control blocks and modules.

You can modify the logon message pointed to by register 1 that is passed to the interpret routine. However, remember these two points:

- Telnet does not look at the changed storage; it is passed as user data to the application.
- You should modify with caution, as modification outside the message storage boundaries could result in Telnet or TCP/IP stack outages.

The uninterrupted Logon message in the parameter list should not be changed as it is not passed as user data to the application.

ENDINTAB macroinstruction

Use the ENDINTAB macroinstruction to define the end of an interpret table. Code one ENDINTAB macroinstruction after one or more LOGCHAR macroinstructions to define the end of an interpret table. You can also follow the ENDINTAB macroinstruction with an assembler language END statement.

Syntax

Parameters

name

Specifies an optional name on the macroinstruction. This name is not used by Telnet and is ignored.

Usage notes

- If you code an assembler language END statement, it must be in the format:

```
END name
```

where *name* is the label of the INTAB macroinstruction and specifies the main entry point.

- Follow the ENDINTAB macroinstruction with an assembler language END statement unless the interpret table is to be followed by CSECTs containing one or more user-written APPLID routines.

Telnet LU exit setup

You can code LU exit routines to specify the LU name used to represent the client. You can optionally return a USS table name (3270 or SCS format) or an Interpret table name to be used by Telnet. The entry point name must match the routine name specified as the LUGROUP group name. Each LU exit routine specified must be assembled and link-edited as a stand-alone load module.

The LU exit can be driven multiple times. If the LUNAME returned by the exit cannot be registered, the exit is driven again for a different LUNAME. If the same name is returned, the connection fails. If a different name is returned, it is registered. If registration fails for the second name, the exit is driven a third time, and the *no additional retry flag* is activated. If the second name is again returned, the connection is terminated. If a third name is returned, registration is attempted again. If registration fails, the connection is terminated.

The LUNAME exit can be mapped as GENERIC or SPECIFIC. If both mappings are present, and the client presents Telnet with an LUNAME, the SPECIFIC mapping is attempted. If this attempt fails, the GENERIC mapping is also attempted. This conforms with the process used when TELNET assigns LUNAMES.

Telnet LU exit setup operation

The LU exit routine runs synchronously in pageable storage under the control of Telnet; it is not under the control of the application program. The LU exit Routine can use non-reentrant code. Telnet ensures that only one process at a time calls the LU exit so it can maintain local storage in the routine for LU name management. The LU exit cannot perform I/O operations. An I/O request causes the routine to terminate abnormally. The routine gets control in supervisor state with the Telnet storage key. Errors in the LU exit might damage Telnet or the entire TCP/IP stack. Telnet monitors the number of abends by the LU exit. If 3 abends occur within a 10-minute period, the LU exit is disabled by Telnet. Telnet fails any future LU exit lookup without calling the LU exit.

Mapping rules apply to the LU exit as if it were an LU group. For example, if the LU exit is mapped to a Client Identifier as a Specific group, only connections requesting specific LUs use the LU exit. The only difference between an LU group and an LU exit is whether Telnet or the LU exit generates the LU name to use. At this time, the LU exit must be used on the LUMAP or PRTMAP statement alone. If Associated Printer function is being used on the LUMAP statement, neither the LU group nor the PRT group can be an LU exit. If the LU assigned to the connection is defined in LU groups mapped by both a LUG statement and an LUMAP/PRTMAP statement, neither LU group can be defined as an LU exit.

In addition to the several Client Identifiers passed to the LU exit using the parameter list pointed to by Register 1, the parameter list also includes any LU names or ranges that were coded in the LUGROUP and

the requested application name, if specified. Telnet does not use the LU list. The LUGROUP can be defined without any LUs specified. The LUs specified can be used as seed values if the LU name exit wants to use them.

Version 2 of the LU exit function supports USS/Interpret table name specification. The parameter list for version 2 has been expanded to include specification of a 3270 format USS table name, SCS format USS table name, or an Interpret table name. Be sure your LU Exit checks the version number before accessing the expanded parameter list area. These fields are filled in with the mapped values, if they exist, by Telnet before the LU exit is called. If a name or names are changed upon return, Telnet attempts to load the table into storage if not already loaded.

Rules: The following rules apply:

- USS/Interpret table names are honored only for TN3270E connections. For TN3270E connections, the LU exit assigns an LU during connection negotiation. The LU exit is able to specify the USS table before end users receive their first USSMSG10 screen. For TN3270 connections or connections with the SIMCLIENTLU option defined, the LU exit does not assign an LU until an application is chosen. In these cases, the end user receives a Telnet solicitor panel or a USSMSG10 message from a profile-mapped USS table. When the LU exit is called for these connections, the PL_UssIgnored flag is on, indicating that the USS tables or Interpret tables assigned by the LU exit are ignored.
- Telnet loads the USS/Interpret tables the first time they are assigned by the LU exit. If a table fails to load, the table mapped by the profile is used. If no profile mapping exists, a solicitor panel is sent to the client. If both 3270-format and SCS-format tables are specified by the exit, both tables must successfully load for the pair to be used.
- After the USS/Interpret tables that were assigned by the LU exit are loaded, Telnet replaces the currently assigned profile-mapped USS/Interpret tables (3270 or SCS format) with the LU exit tables. Telnet uses the new tables for all USS messages and commands.
- Setting the table name field to blanks indicates to Telnet that no table should be used for that table type. For example, if the profile mapping maps the EZBTPUST/EZBTPSCS value to a connection and the exit returns the EZBTPUST/, Telnet uses EZBTPUST only.
- The LU exit can assign USS/Interpret tables for TN3270E connections only. SIMCLIENTLU must not be coded. If an SCS-format table name is specified, that table is used; otherwise the 3270 format table is used.

The LU exit table specified remains in effect until the connection is dropped.

You can determine the USS tables used by a particular LU exit by issuing an OBJ display command for the LuGroup that is the LU exit. For example, if you defined the following LU group LUGROUP MyLuExit,EXIT ENDLUGROUP, you can issue a D TCP/IP,,TELNET,OBJ,ID=MyLuExit command to view all USS tables loaded to support the LU Exit.

You can make changes to a USS table, and the changes become effective after the next V TCP/IP,,OBEYFILE is issued. Whenever a V TCP/IP,,OBEYFILE is issued, the USS tables specified by the LU Exit are reloaded.

Telnet specifies the function code in Register 0.

The following function codes are used:

- Function code 01 indicates the LU exit should create an LU name. Any algorithm can be used in the LU exit to generate an LU name. The LU exit either returns the LU name in the LU name field of the parameter list with a return code of 0 in Register 15, or the LU exit indicates that no LU name should be used and specifies a return code of 8 in Register 15. If Register 15 is 0, Telnet uses the LU name value, tries to register the LU name in the Telnet master LU database, and then assigns the LU to the connection. At this time, any nonzero return code is treated by Telnet as an indicator that the function did not work.

Guideline: Use 8. In future releases, other values might be used to indicate specific reasons.

- Function code 02 indicates the LU name is no longer representing the connection and is being unassigned from the Telnet connection. The LU name is now available for assignment to another connection. It is up to the LU exit to manage the list of available LU names. If LU names are not reused,

the LU exit might ignore the unassign function code. Whether or not the LU exit records the state change, Telnet ignores the return code value and deregisters the LU name from the Telnet master LU database.

- Function code 03 indicates the LU name is being deactivated because the operator issued the V TCPIP,,T,INACT,luname command or the ACB failed to open. If the LU exit is tracking the state of LU names, an inactive LU should be considered not available to represent a client. Whether or not the LU exit changes the LU state within the exit, Telnet ignores the return code value, adds the LU name to the inactive LU list, and does not allow it to be registered in the master LU database.
- Function code 04 indicates the LU name is being activated because the operator issued the V TCPIP,,T,ACT,luname command. If the LU exit is tracking the state of LU names, the LU name should be considered available to represent a client. Whether or not the LU exit changes the LU state within the exit, Telnet ignores the return code value, removes the LU name from the inactive LU list, allows registration in the master LU database, and allows assignment to a Telnet connection.
- Function code 05 indicates the LU name is already in use. If the exit returns a different LU name, Telnet attempts to register this new LU name in the Telnet master LU name database. Telnet tries up to three LU names. If the third LU name is in use, Telnet notifies the exit with a flag bit indicating that no additional retries are attempted. Upon return from the third notification, Telnet does not look at the LU name field and fails the connection. Other connections have access to the exit between retry attempts.

If a specific LU name was requested by the client and it is not an LUGROUP name, that LU name is in the LU name field of the parameter list as input to the Exit. The LU exit can leave that LU name or override it with another name. In either case, Telnet then attempts to register the returned LU name.

If the LU name is already assigned or has been deactivated, Telnet fails the connection but does not notify the LU exit that the LU was already in use. If the OPEN ACB fails, Telnet notifies the Exit that the LU name is being deactivated in the Telnet Registration database by calling the LU exit with function code 03. If the LU name is activated using the Telnet ACT command, the LU exit is called with function code 04, indicating the LU name is reactivated.

Requirements for LU exit routines

This topic lists the requirements for LU exit routines.

```
Entry from:   Telnet
Entry point:  Routine name
```

Contents of registers at entry

The contents of registers at entry are as follows:

```
Register 0:    Function code.  01 - Assign LU
                                02 - Unassign LU
                                03 - Inact LU
                                04 - Act LU
                                05 - LU in use
Register 1:    Address of parameter list specifying LU name, LUGROUP, and
               client known information.

Register 13:   Address of a 72-byte save area provided by Telnet.

Register 14:   Return address.

Register 15:   Address of entry point of this routine.
```

Contents of registers at exit

The contents of registers at exit are as follows:

```
Registers 0-14: Restored to condition at entry.

Register 15:    Return code:
```

00 - Use the LU name in the parameter area.
08 - LU name is not to be used

If the name of the LU contains fewer than 8 characters, pad with blanks to the right to provide a name with 8 characters. The LU exit routine must save and restore the contents of registers 2-14 when receiving and passing control. Do not modify any values in the parameter list other than the LU name field. Do not alter more than the 8 bytes needed for the LU name. The R15 return code indicates to Telnet what action to take.

LU exit routine parameter list

When the exit gets control, the address of the following parameter list is in register 1:

Dec Offset	Size (Bytes)	Description	Input or Output	Assign/Unassign Inact (ACB fail)	Inact/ACT Command
				Value if not set	Value if not set
0	8	LU name	Both	Blanks	Always present
8	1	Flag Bytes			
		'80'x - 1 Client is a printer	Input	Always present	Always 0
		0 Client is a terminal			
		'40'x - 1 No additional retry	Input	Always present	Always 0
		0 retry will be allowed			
		'20'x - 1 IP Address is in IPv6	Input	Always present	Always 0
		format			
		0 IP Address is in IPv4 format			
		'10'x - 1 USS/SCS/Int tables	Input	Always present	Always 0
		assigned by exit ignored for			
		this connection			
		0 USS/SCS/Int tables assigned			
		by exit will be used			
9	1	Parameter list Version level	Input	Always set	Always set
10	1	Available byte	Both	Always 0	Always 0
11	1	Available byte	Both	Always 0	Always 0
12	16	Client IP address in hex	Input	Always set	Always 0
28	4	Client Port	Input	Always set	Always 0
32	16	Destination IP address in hex	Input	Always set	Always 0
48	4	Destination Port	Input	Always set	Always 0
52	16	Linkname	Input	Blanks	Always Blanks
68	8	Userid from Client Certificate	Input	Blanks	Always Blanks
76	4	Ptr to hostname structure	Input	0	Always 0
80	8	Application netid	Input	Blanks	Always Blanks
88	8	Application name	Input	Blanks	Always Blanks
96	8	Userid from solicitor panel	Input	Blanks	Always Blanks
104	4	Ptr to LUGroup structure	Input	0	0
108	8	USS table name - 3270 format	Both	Blanks	Always Blanks
116	8	USS table name - SCS format	Both	Blanks	Always Blanks
124	8	Interpret table name	Both	Blanks	Always Blanks
132	16	Reserved	Both	Blanks	Always Blanks
Hostname structure					
0	1	Total length of Hostname	Input	0	
1	255	Client hostname	Input		
LuGroup structure					
0	4	Number of single LU names	Input		
4	n	List of all single LU names, each 8 characters			
		(n=8*number of LUs)	Input	0	
n+4	4	Number of LU range structures	Input	0	
n+8	m	List of all LU range structures, each 24 characters (low/high/variant)			
		(m=24*number of structures)	Input		

Chapter 13. EXPRESS LOGON using DCAS

The Digital Certificate Access Server (DCAS) is a host-based server that provides some distributed z/OS security server services. The most common service is Pass Ticket (like a password) generation services. It typically works in conjunction with SSL-authenticated clients that provide logon services on behalf of end users (typically workstation users) that want to log on to host applications. This allows users to log on to host applications without having to know their password, and possibly even their user ID. On the host, DCAS works with the resident security server, such as RACF, to provide this function.

Implement TLS security using AT-TLS policies. For more information about using AT-TLS policies, see [Customizing DCAS for TLS/SSL in z/OS Communications Server: IP Configuration Guide](#).

Requirement: The application Pass Ticket generation must be configured in RACF.

DCAS can support several different client-types for express logon. For additional overview and configuration information about Express Logon, see [z/OS Communications Server: IP Configuration Guide](#).

This topic contains the following information:

- [“Starting Digital Certificate Access Server” on page 579](#)
- [“Digital Certificate Access Server \(DCAS\) environment variables” on page 581](#)
- [“Digital Certificate Access Server \(DCAS\) sample procedure \(EZADCASP\)” on page 581](#)
- [“Digital Certificate Access Server \(DCAS\) configuration file keywords and parameters” on page 582](#)

Starting Digital Certificate Access Server

You can start the DCAS from the z/OS UNIX shell or with an MVS started procedure using optional parameters for debugging, logging, and specifying the configuration file. To start the DCAS from the z/OS UNIX shell, use the following format:

```
dcas <parameter_1> <parameter_2> <parameter_3> &
```

To start the DCAS from an MVS started procedure, use the following format:

```
PARM=.../<parameter_1> <parameter_2> <parameter_3>
```

The following optional parameters can be used with both the DCAS UNIX command and the MVS started procedure:

-d or -D

Indicates debugging. The following levels apply:

- 1**
Specifies log error and warning messages.
- 2**
Specifies log error, warning, and informational messages.
- 3**
Specifies log error, warning, informational, and debug messages.

-l or -L

Indicates logging to SYSLOGD or to a designated log file. If you do not specify this parameter, logging defaults to /tmp/dcas.log.

If you specify a debug level, but not logging, then the DCAS attempts to open the default log file /tmp/dcas.log. If this fails, debugging is turned off.

For SYSLOGD, the DCAS uses the log facility local0.

-c or -C

Indicates the requested configuration file (for example, /u/userx/passtick.conf). If you do not specify this parameter, the DCAS looks for the configuration file using the following search order:

1. DCAS_CONFIG_FILE environment variable
2. /etc/dcas.conf
3. tsouserid.DCAS.CONF
4. TCPIP.DCAS.CONF

Restriction: If the DCAS does not find a valid configuration file, it does not start.

The /tmp/dcas.*tcpname*.pid is a temporary DCAS pid file that the DCAS creates. This file contains the process ID of the current invocation of the DCAS.

Restrictions:

- If /tmp/dcas.*tcpname*.pid is a symbolic link, it must have an owning UID or GID that matches the EUID or EGID that is assigned to the DCAS.
- If /tmp/dcas.*tcpname*.pid is a hard link or the target of a hard link, users that are outside the owner or group of the directory in which /tmp/dcas.*tcpname*.pid is stored cannot have write access to the directory. Additionally, write access to /tmp/dcas.*tcpname*.pid must be limited to the owning UID or group, for example, --w--w----permissions.

Digital Certificate Access Server (DCAS) sample procedure (EZADCASP)

```
//DCAS      PROC
//*
//*  IBM Communications Server for z/OS
//*  SMP/E distribution name: EZADCASP
//*
//*  5694-A01 (C) Copyright IBM Corp. 2000, 2005
//*  Licensed Materials - Property of IBM
//*  "Restricted Materials of IBM"
//*  Status = CSV1R7
//*
//*  Function: Sample procedure for running the Digital
//*            Certificate Access Server (DCAS)
//*
//DCAS      EXEC PGM=EZADCDMN,REGION=4096K,TIME=NOLIMIT,
//          PARM='POSIX(ON) ALL31(ON) / -d 1 -l SYSLOGD'
//*
//*** Notes:
//*
//* - DCAS can also be invoked from the Unix System Services shell
//*   as a shell command: dcas
//*
//* - The z/OS Secure Socket Layer (SSL) product libraries must
//*   be accessible at runtime to DCAS- hlq.mlq.SGSKLOAD.
//*
//* - The system link list concatenation must contain the TCP/IP
//*   runtime libraries and the C runtime libraries. If they are
//*   not in the link list concatenation, this procedure will need
//*   to be changed to STEPLIB to them.
//*
//* - To pass parameters to DCAS, specify them after the final slash
//*   on the PARM statement. For example:
//*       // PARM=('POSIX(ON) ALL31(ON)',
//*       // 'ENVAR("LIBPATH=/usr/lib")/-d 3 -l SYSLOGD')
//*
//* - Other examples
//* // PARM=('POSIX(ON) ALL31(ON) TERMTHDACT(UATRACE) TRAP(ON)',
//* // 'ENVAR("DCAS_CONFIG_FILE=/u/us1/xxx.conf")/ -d 3 -l SYSLOGD')
//*
//*
//*
//STDENV    DD DUMMY
//SYSPRINT  DD SYSOUT=*,DCB=(RECFM=F,LRECL=80,BLKSIZE=80)
//SYSIN     DD DUMMY
//SYSERR    DD SYSOUT=*
//SYSOUT    DD SYSOUT=*,DCB=(RECFM=F,LRECL=80,BLKSIZE=80)
//CEEDUMP   DD SYSOUT=*,DCB=(RECFM=FB,LRECL=132,BLKSIZE=132)
```

Figure 21. DCA server configuration file sample

Digital Certificate Access Server (DCAS) environment variables

Table 40 on page 581 provides a list of environment variables used by DCAS that can be tailored to a particular installation:

Table 40. DCAS environment variables			
Environment variable	Server, Client or Command-type application	Description	Any specific coding rules (or a link to syntax)
DCAS_CONFIG_FILE	DCAS (Digital Certificate Access Server)	Identifies the location of the DCAS configuration file	None

Digital Certificate Access Server (DCAS) configuration file keywords and parameters

This topic describes the keywords and parameters that are used in the DCAS configuration file. For information on required AT-TLS policies for DCAS, see [Customizing DCAS for TLS/SSL in z/OS Communications Server: IP Configuration Guide](#).

The following list shows some rules for processing a DCAS configuration file:

- The # symbol as the first character on a line in a configuration file indicates a comment. The format for specifying keywords and values is <keyword> <value> with a space between the keyword and the value.
- If a keyword is unrecognized as one of the valid DCAS keywords, a message is sent to the console indicating a keyword that is not valid was detected, but that processing continues. If the same keyword is specified more than one time in the profile, the last value specified for that keyword is used.
- You can use upper or lowercase for keywords and most values, but values representing file names in the z/OS UNIX are case sensitive.
- z/OS UNIX file names can be 128 characters or fewer in length. This includes the path name, file name, forward slashes (/), and periods (.). File names longer than 128 characters are truncated.

CLIENTAUTH

Use the CLIENTAUTH keyword and parameters to specify client authentication.

Tip: You must also configure the following values in the corresponding AT-TLS policy:

- TTLSEnvironmentAction HandshakeRole ServerWithClientAuth
- TTLSEnvironmentAction -> TTLSEnvironmentAdvancedParms
 - LOCAL1 - ClientAuthType Required
 - LOCAL2 - ClientAuthType SAFCHECK

Parameters

LOCAL1

Specifies that the SSL handshake process authenticates the client certificate as well as the server certificate. This check verifies the client has received a certificate from a trusted certificate CA.

LOCAL2

Specifies that the SSL handshake process authenticates the client certificate and provides additional access control through the installation's SAF-compliant security product (for example, RACF). The following conditions apply:

- LOCAL2 verifies the client certificate has an associated user ID defined to the security product. The certificate must first be defined to the security product to obtain this validation. For more information about adding certificates to RACF, see the description of the RACDCERT command in the [z/OS Security Server RACF Command Language Reference](#).
- For security products that support the SERVAUTH class, installations can also obtain a more granular level of access control. If the installation has activated the SERVAUTH class and provided a profile for the DCAS in the SERVAUTH class, only users specified in the profile are allowed to connect to the port. The security product profile name is specified using the following format:

```
EZA.DCAS.sysname
```

where *sysname* is the name of the MVS system image.

Tip: Client certificate refers to the DCAS Client:

- TN3270 middle-tier server in the case of the IBM Express Logon Feature (ELF)
- Host on Demand (HoD) or HATS for WebExpress Logon
- The client connecting to DCAS for other enhanced logon solutions

IPADDR

Use this keyword to define the IP address to which the DCAS binds.

Tip: For TLSMECHANISM ATTLS, you must set the TTLSRule LocalAddr parameter in the corresponding AT-TLS policy to match the IPADDR value.

Parameters

ipaddr

Specifies the IP address or host name to which the DCAS binds. If you do not specify *ipaddr*, the DCAS binds to the IPv4 INADDR_ANY address or to the IPv6 unspecified address (*in6addr_any*).

Restriction: Scope information cannot be specified with the IP address or the host name.

Requirement: The TCP/IP stack must be IPv6-enabled if an IPv6 address (or host name which resolves to an IPv6 address) is specified.

PORT

Use the PORT keyword to define a basic port to the DCAS.

You must set the TTLSRule LocalPortRange parameter in the corresponding AT-TLS policy to match the PORT value.

Parameters

8990

Specifies the port over which the DCAS accepts incoming requests. Port 8990 is the default.

num

Specifies a particular port number.

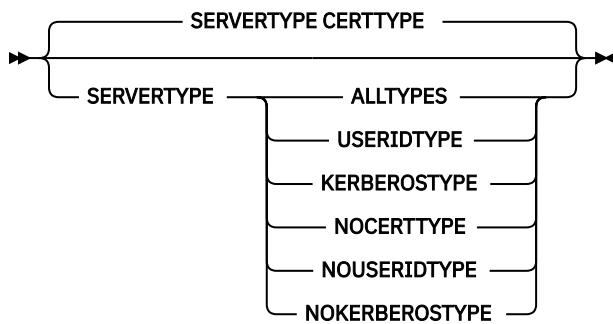

SERVERTYPE

Use the SERVERTYPE keyword and parameter to specify the type of input the DCAS server receives.

The SERVERTYPE keyword definition can be specified multiple times in the DCAS configuration file.

Subsequent definitions are logically ORed. For example, defining SERVERTYPE ALLTYPES and then SERVERTYPE NOUSERIDTYPE means that DCAS no longer accepts a user ID as input.

Restriction: Because SERVERTYPE CERTTYPE is the default, it is not valid to only specify SERVERTYPE NOCERTTYPE.

Parameters

Guideline: For any SERVERTYPE parameter, DCAS returns a Pass Ticket for the application name that it receives from the client.

SERVERTYPE CERTTYPE

Specifies that DCAS accepts only a X.509 certificate and application name as input. This is the default.

SERVERTYPE ALLTYPES

Specifies that DCAS accepts any form of currently supported and future inputs. This enables DCAS to accept a x.509 certificate, and application name (SERVERTYPE CERTTYPE) as well as a user ID and application name (SERVERTYPE USERIDTYPE).

SERVERTYPE USERIDTYPE

Specifies that DCAS accepts only a user ID and application name as input.

SERVERTYPE KERBEROSTYPE

Specifies that DCAS accepts a Kerberos principal name and application name as input.

SERVERTYPE NOCERTTYPE

Specifies that DCAS does not accept the x.509 certificate and application name as input. You can use this to turn off a previous SERVERTYPE CERTTYPE parameter.

SERVERTYPE NOUSERIDTYPE

Specifies that DCAS does not accept user ID and application name as input. You can use this to turn off a previous SERVERTYPE USERIDTYPE parameter.

SERVERTYPE NOKERBEROSTYPE

Specifies that DCAS does not accept a Kerberos principal name and application name as input. Use this parameter to turn off a previous SERVERTYPE KERBEROSTYPE parameter.

Requirements: You must specify certain values for following IBM-enhanced logon solutions:

- Express Logon Feature (ELF) requires a SERVERTYPE value of CERTTYPE or ALLTYPES.
- Web Express Logon (WEL) requires a SERVERTYPE value of USERIDTYPE or ALLTYPES.

For enhanced logon solutions other than those listed, see your product documentation for the SERVERTYPE value you need to specify. You should have an understanding of the DCAS function required by the solution prior to configuring the SERVERTYPE parameter because the data that DCAS provides is highly sensitive.

Usage notes

- The KERBEROSTYPE support enables the DCAS client to provide a Kerberos principle name and application ID. The Kerberos principal name must be mapped to a RACF user ID. This allows DCAS to provide a Pass Ticket for the user ID and application name. See [z/OS Security Server RACF Security Administrator's Guide](#) for information about defining a KERBLINK profile.

The DCAS server has been enhanced to provide the new function. This requires that the administrator of the single-signon solution use RACF or a similar security product to map a valid z/OS user ID to a Kerberos principal name. In RACF, do this by creating a KERBLINK profile in RACF.

See [z/OS Security Server RACF Security Administrator's Guide](#) for a description of Kerberos principal names and how to map them to user IDs.

TCPIP

Use the TCPIP keyword to specify the active TCP/IP stack name with which the DCAS establishes affinity.

➤ TCPIP — stackname ➤

Parameters

stackname

Specifies the name of the TCP/IP stack with which the DCAS establishes affinity.

TLSMECHANISM

The TLSMECHANISM keyword is deprecated. AT-TLS must be used to implement TLS security for DCAS. For more information about using AT-TLS policies, see [Customizing DCAS for TLS/SSL in z/OS Communications Server: IP Configuration Guide](#).

➤ TLSMECHANISM — ATTLS ➤

Parameters

ATTLS

AT-TLS policies are used for TLS/SSL.

Steps for setting up RACF for Digital Certificate Access Server (DCAS)

This topic describes how to set up RACF for DCAS.

Procedure

Perform the following steps to set up RACF for DCAS:

1. Define a user ID as superuser to OMVS services.

The server requires that you define the user ID from which the server is started to be defined to use OMVS services as a superuser. You can configure the OMVS(UID(0)) on the ADDUSER command. However, if the user ID already exists, the ADDUSER fails and the user ID is not altered to superuser. The ALTUSER value sets the user ID to superuser whether the user ID existed before or the ID was just created by the ADDUSER command.

```
ADDUSER DCAS ALTUSER DCAS DFLTGRP(OMVS) OMVS(UID(0)HOME('/'))
```

2. Give the user ID access to operator commands.

If the OPERCMDS class profile MVS.SERVMMGR.DCAS is defined to control who can start DCAS, then the user ID that starts DCAS must have CONTROL access to the profile. Use the following commands to provide access:

```
RDEFINE OPERCMDS(MVS.SERVMMGR.DCAS) UACC(NONE)
PERMIT MVS.SERVMMGR.DCAS CLASS(OPERCMDS) ACCESS(CONTROL)
ID(DCAS)
SETOPTS RACLIST(OPERCMDS) REFRESH
```

3. Provide a RACF definition for MVS startup.

If the server is started as an MVS procedure, use the following RACF definitions to define the server to RACF:

```
RDEFINE STARTED DCAS.* STDATA(USER(DCAS)) SETROPTS RACLIST(STARTED) REFRESH
```

Chapter 14. File Transfer Protocol

This topic contains z/OS File Transfer Protocol (FTP) client and server configuration information and includes the following information:

- “FTP server cataloged procedure (FTPD)” on page 587
- “FTP server cataloged procedure (FTPD) parameters” on page 589
- “FTP configuration statements in FTP.DATA” on page 609
- “SOCKS configuration statements in SOCKSCONFIGFILE” on page 792

FTP clients and servers both use a configuration file, referred to as FTP.DATA. FTP.DATA can be used to customize FTP behavior. The server's FTP.DATA file customizes the behavior of the server system, and the client's FTP.DATA file customizes the behavior of the client system.

For example, if you want to create data sets on the server's system with a logical record length of 80 characters, and create data sets on the client's system with a logical record length of 256, perform the following steps:

1. Specify the LRECL 80 configuration statement in the FTP server's FTP.DATA configuration file.
2. Specify the LRECL 256 configuration statement in the FTP client's FTP.DATA configuration file.

The setting in the FTP server's configuration file is used by the server when the user creates a file on the server's system with an FTP subcommand, such as PUT. Likewise, the setting in the FTP client's configuration file is used by the FTP client when the user creates a file on the client's system with an FTP subcommand, such as GET.

Guideline: The client setting does not override the server setting. Instead, the server setting affects data sets created on the server's system, while the client setting affects data sets created on the client system.

FTP server cataloged procedure (FTPD)

The following sample shows a start procedure for the FTP server. No start procedure is required for the FTP client.

```
//FTPD  PROC MODULE='FTPD',PARMS=' '
//*****
//*      Descriptive Name:      FTP Server Start Procedure  *
//*      File Name:             tcpip.SEZAINST(EZAFTPAP)      *
//*                               tcpip.SEZAINST(FTPD)         *
//*      SMP/E Distribution Name: EZAFTPAP                   *
//*                               *                           *
//*      Licensed Materials - Property of IBM                *
//*      "Restricted Materials of IBM"                        *
//*      5694-A01                                              *
//*      (C) Copyright IBM Corp. 1995, 2005                  *
//*      Status = CSV1R7                                       *
//*****
//*
//* SET  PARM1=TCPIVP.TCPPARMS(TCPDATA)
//*
//FTPD  EXEC PGM=&MODULE,REGION=4096K,TIME=NOLIMIT,
//      PARM=' /&PARMS '
//*
//*  Uncomment the SET statement above when using the next two lines.
//*  PARM=(' ENVAR("RESOLVER_CONFIG=/'&PARM1''")',
//*  ' /&PARMS ')
//*
//*  PARM=(' ENVAR("_BPX_JOBNAME=myftp")',
//*  ' /&PARMS ')
//*
//*  PARM=(' ENVAR("KRB5_SERVER_KEYTAB=1")',
//*  ' /&PARMS ')
//*
//***** IVP Note *****
//*
```

```

/* If executing the FTP installation verification procedures (IVP),
/* - Comment the first PARM card and uncomment both lines of the
/* second PARM card
/* - Uncomment the appropriate SYSFTPD and SYSTCPD DD cards for the IVP
/*
/******
/***** _BPX_JOBNAME Note *****
/*
/* The environment variable _BPX_JOBNAME can be specified
/* here in the FTPD procedure, so that all of the logged on
/* FTP users will have the same jobname. This can then
/* be used for performance control and identifying all FTP users.
/* To use this:
/* - Comment the first PARM card and uncomment both lines of the
/* third PARM card
/*
/******
/***** KRB5_SERVER_KEYTAB Note *****
/*
/* The environment variable KRB5_SERVER_KEYTAB can be specified
/* here in the FTPD procedure, so that the FTP server will use the
/* local instance of the Kerberos security server to decrypt tickets
/* instead of obtaining the key from the key table.
/* To use this:
/* - Comment the first PARM card and uncomment both lines of the
/* fourth PARM card
/*
/******
/*
/* The C runtime libraries should be in the system's link
/* list or add them to the STEPLIB definition here. If you
/* add them to STEPLIB, they must be APF authorized.
/*
/* To submit SQL queries to DB2 through FTP, the DB2 load
/* library with the suffix DSNLOAD should be in the system's
/* link list, or added to the STEPLIB definition here. If
/* you add it to STEPLIB, it must be APF authorized.
/*
//CEEDUMP DD SYSOUT=*
/*
/* SYSFTPD is used to specify the FTP.DATA file for the FTP
/* server. The file can be any sequential data set, member
/* of a partitioned data set (PDS), or HFS file.
/*
/* The SYSFTPD DD statement is optional. The search order for
/* FTP.DATA is:
/*
/* SYSFTPD DD statement
/* jobname.FTP.DATA
/* /etc/ftp.data
/* SYS1.TCPPARMS(FTPDATA)
/* tcpip.FTP.DATA
/*
/* If no FTP.DATA file is found, FTP default values are used.
/* For information on FTP defaults, see z/OS Communications
/* Server: IP Configuration Reference.
/**SYSFTPD DD DISP=SHR,
/* DSN=TCPIP.SEZAINST(FTPDATA)
/**SYSFTPD DD DISP=SHR,
/* DSN=TCPIVP.TCPPARMS(FTPDATA)
/*
/* SYSTCPD explicitly identifies which data set is to be
/* used to obtain the parameters defined by TCPIP.DATA
/* when no GLOBALTCPIPDATA statement is configured.
/* See the IP Configuration Guide for information on
/* the TCPIP.DATA search order.
/* The data set can be any sequential data set or a member of
/* a partitioned data set (PDS).
/**SYSTCPD DD DISP=SHR,
/* DSN=TCPIP.SEZAINST(TCPDATA)
/**SYSTCPD DD DISP=SHR,
/* DSN=TCPIVP.TCPPARMS(TCPDATA)
/*

```

Figure 22. Sample start procedure for the daemon

FTP server cataloged procedure (FTPD) parameters

The system parameters required by the FTP server are passed by the PARM parameter on the EXEC statement of the FTPD cataloged procedure. Add your parameters to PARMs= ' in the PROC statement of the FTPD cataloged procedure, making certain that:

- Each parameter is separated by a blank.
- All parameters are in uppercase, unless the security product administrator has enabled mixed-case password support. In that case, any password you supply as a parameter must be entered in the correct case.

For example: `//FTPD PROC MODULE='FTPD',PARMS='TRACE ANONYMOUS PORT 21'`

ANONYMOUS

Specifying this start option is equivalent to coding the ANONYMOUS statement in FTP.DATA with no parameters. See [“ANONYMOUSLEVEL \(FTP server\) statement” on page 638](#) and [“ANONYMOUS \(FTP server\) statement” on page 630](#) for more information.

ANONYMOUS=user_id

Specifying this start option is equivalent to coding the ANONYMOUS *user_id* statement in FTP.DATA. See [“ANONYMOUSLEVEL \(FTP server\) statement” on page 638](#) and [“ANONYMOUS \(FTP server\) statement” on page 630](#) for more information.

ANONYMOUS=user_id/password

Specifying this start option is equivalent to coding the ANONYMOUS *user_id/password* statement in FTP.DATA. See [“ANONYMOUSLEVEL \(FTP server\) statement” on page 638](#) and [“ANONYMOUS \(FTP server\) statement” on page 630](#) for more information.

Restriction: Do not code a password phrase as *password*.

ANONYMOUS=user_id/SURROGATE

Specifying this start option is equivalent to coding the ANONYMOUS *user_id/SURROGATE* statement in FTP.DATA. See [“ANONYMOUSLEVEL \(FTP server\) statement” on page 638](#) and [“ANONYMOUS \(FTP server\) statement” on page 630](#) for more information.

Requirement: To use this option, ANONYMOUSLEVEL must be greater than or equal to 3.

AUTOMOUNT

Permits a DASD volume to be mounted when attempts are made to access data sets on that volume.

AUTORECALL

Permits data sets migrated by a storage manager, such as hierarchical storage manager (HSM), to be recalled automatically.

DATASETMODE

Treats all lower qualifiers of address space names as part of the same directory. This affects the behavior of DIR, LS, MGET, and MDLETE because all lower qualifiers are returned.

DIRECTORYMODE

Treats each level of an address space name as if it were a directory. This affects the behavior of DIR, LS, MGET, and MDLETE because only the next lower qualifier is returned.

INACTIVE number_seconds

Sets the inactivity timeout to the specified number of seconds. A control connection inactive for this amount of time is closed. The default inactivity timeout is 300 seconds (5 minutes). The maximum inactive time is 86 400 seconds. A value of 0 disables the inactivity timer, and inactive control connections do not time out.

NOAUTOMOUNT

Prevents a DASD volume from being mounted when attempts are made to access data sets on that volume.

NOAUTORECALL

Prevents data sets migrated by a storage manager, such as HSM, from being recalled automatically. Migrated data sets can still be deleted even though NOAUTORECALL is specified.

Restriction: Only sequential and whole partitioned data sets can be deleted without recalling. Partitioned data set members require the whole data set to be recalled.

PORT *port_num*

Accepts incoming requests on the specified (decimal) port number rather than the port specified in `/etc/services` or the default port of 21. (*port_num* – 1) is used for data transfer. The maximum port number is 65534.

TRACE

Running TRACE might affect performance and should only be used when diagnosing problems with FTP sessions.

FTP server user exits

To limit access to an FTP server, you can use any of the user exits described in this topic. The FTP server provides increased security by using user exits.

A user exit is passed the address of a parameter list in register 1. The parameter list is a series of pointers to values. The first word of the parameter list always points to the return code. If the user exit sets the return code to 0, processing continues as normal. If the return code is not 0, authorization is denied and the user receives a negative reply indicating that the command has failed. Upon entry, the return code is 0, so a correct return can be indicated by leaving the return code alone. The return code field in the FTPOSTPR exit is included for consistency; it has no effect on processing.

The second word of the parameter list always points to a word containing the number of parameters that follow. This helps handle any future releases that might increase the number of parameters in these parameter lists.

The remainder of the parameter list points to values the FTP user exit uses in its processing.

Requirements:

- The user exit load modules must be in a cataloged data set and placed in an APF-authorized library to which the FTP server has access by way of STEPLIB, linklist, or LPA.
- The authorization state (JSCBAUTH) must be the same after exiting from the user exit as it was upon entry.
- User exit routines must be reentrant.
- User exit routines are invoked in TCB mode, problem program state, with AMODE(31). If the user exit routine changes a setting, the user exit routine must restore the setting before returning to the caller.
- The FTPCHKIP user exit is loaded when the FTP daemon initializes. If you want the FTP daemon to use a new version of this exit routine, you must stop the FTP daemon and start it again.

Rule: All data areas that are passed to the exit, including the Language Environment save area stack, above the 31 bit addressing line. If the exit routine uses any system services that require data areas below the 24 bit addressing line, the exit routine must obtain the necessary storage below the line and copy any data values there.

Guidelines:

- If you are debugging a user exit routine, you should have a test version of a server to work with so that you can stop and start without affecting other users. You can do that by putting a PORT parameter in the EXEC statement of the FTP JCL, such as `PARMS='PORT 1073'`. To connect to this server, enter the following code:

```
FTP remoteHost 1073
```

You can use any number as a port number for your test FTP server. IBM suggests that you choose a number that does not conflict with any well-known port numbers used on your host.

- z/OS FTP follows the MVS search order to load the FTP exit routines. If you are not using the user exit facility, put a dummy user exit load module in the first library in the MVS search order. This prevents

other users from putting their own modules in a library later in the concatenation sequence. This also increases the need to have that library protected using SAF.

Restriction: You cannot use the System Programming C Facilities for the user exits.

See the detailed information about the following user exits:

- [“The FTCHKCMD user exit” on page 591](#)
- [“The FTPOSTPR user exit” on page 593](#)
- [“The FTCHKIP user exit” on page 595](#)
- [“The FTCHKPWD user exit” on page 596](#)
- [“The FTCHKJES user exit” on page 598](#)
- [“The FTP server SMF user exit” on page 599](#)

Sample server user exits

You can find sample user exit routines in SEZAINST:

User exit	Location of sample
FTCHKIP	SEZAINST(FTCHKIP)
FTCHKPWD	SEZAINST(FTCHKPWD)
FTCHKCMD	SEZAINST(FTCHKCMD), SEZAINST(FTCHKCM1), SEZAINST(FTCHKCM2)
FTCHKJES	SEZAINST(FTCHKJES)
FTPOSTPR	SEZAINST(FTPOSTPA), SEZAINST(FTPOSTPR)

The FTCHKCMD user exit

FTCHKCMD is called when the server receives a command to run RETR, STOR, or any other FTP command. The user exit is passed as follows:

- The user ID
- The command
- The command parameters
- The current directory type of MVS or z/OS UNIX
- The file type of SEQ, JES, or SQL
- The current working directory value
- The address of a buffer that can be used to return modified command arguments
- A buffer to hold a 500 reply extension to explain why the exit denied the request
- The socket address structure of the client's control connection
- The socket address structure of the server's control connection
- A buffer containing the session instance identifier
- A 256-byte scratchpad buffer

The exit can accept the command, reject the command, or modify the arguments passed to the command. When the exit rejects the command, the FTP server always replies 500 *User Exit denies Userid userid* from using Command *command*. If the exit routine places text into the 500 reply extension buffer, the FTP server replies to the client with reply code 500 and the supplied text before it replies 500 *User Exit denies Userid userid* from using Command *command*.

The FTP server sometimes replies to a client with the arguments of the subcommand the client sent to the server. For example, if a client enters SITE FNIDDER=FNAT, a 200 message is returned to the

client: 200-Unrecognized parameter 'FNIDDER=FNAT' on site command. For such replies, the command arguments included are those returned by FTCHKCMD rather than those originally entered by the client.

The following parameter list is passed to FTCHKCMD:

Offset

Value

+0

Pointer to the fullword return code. Return 0 to accept the command or to pass new arguments to the command. Return a nonzero value to reject the command.

+4

Pointer to a word containing the number of following parameters (12).

+8

Pointer to the 8-byte user ID that is logged in.

+12

Pointer to the 8-byte command being entered.

+16

Pointer to a string containing arguments after the command. The first halfword of the string contains the number of characters that follow.

+20

4-byte character string with current directory type: MVS or z/OS UNIX (left-aligned).

+24

4-byte character string with current file type: SEQ, JES, or SQL.

+28

Buffer with current directory value. The first bytes hold length of remaining buffer. This is an 1102-byte output buffer in which to return modified argument strings. The first 2 bytes must be initialized to the length of the returned command string.

+32

1102-byte output buffer in which to return modified argument strings. You can modify the arguments passed to the command by placing the modified arguments in this buffer. The first 2 bytes must be initialized to the length of the returned command string.

+36

Pointer to a 71-byte buffer in which to return a 500 reply extension to be used only when the exit denies the request. The exit can place text in this buffer to explain why it denied the request. If the exit supplies text in this buffer, the server appends this text to the string 500-UX- and sends this reply prior to the reply 500 Userid userid from using Command command. The buffer is initialized to blanks before each call to FTCHKCMD.

+40

Pointer to a copy of the socket address structure for the client's control connection. This area is mapped by the SOCKADDR DSECT found in the sample exit. The FAMILY field denotes whether the structure contains an IPv4 or an IPv6 address. When the family is AF_INET, the structure contains an IPv4 address. When the FAMILY is AF_INET6, you must inspect the address itself to determine whether it is an IPv6 address or an IPv4 mapped IPv6 address.

+44

Pointer to a copy of the socket address structure for the server's control connection. This area is mapped by the SOCKADDR DSECT found in the sample exit. The FAMILY field denotes whether the structure contains an IPv4 or an IPv6 address. When the family is AF_INET, the structure contains an IPv4 address. When the FAMILY is AF_INET6, you must inspect the address itself to determine whether it is an IPv6 address or an IPv4 mapped IPv6 address.

+48

Pointer to a buffer containing a 2-byte length followed by the session identifier created by the daemon when the connection was first established for this session. The identifier has a maximum length of 14 bytes and is unique within this instance of the server.

+52

Pointer to a 256-byte scratchpad buffer, which can be used to pass information between user exits. All exits receive a pointer to this buffer except FTCHKIP and FTCHKPWD. FTP does not query or alter the contents of the scratchpad at any time. The extended tracing (DUMP) identifier of the scratchpad is 87. If extended tracing of the scratchpad is requested, the contents are dumped after execution of the user exit.

Restriction: If the exit is used for USER/PASS command processing, the scratchpad buffer should not contain a pointer unless the storage location that is referenced is available to all address spaces.

The FTPOSTPR user exit

FTPOSTPR is called upon completion of the FTP commands RETR, STOR, STOU, APPE, DELE, and RNTD. The user exit is passed as follows:

- The user ID
- The client IP address
- The client port number
- The current directory type
- The length of the parameter string
- The current working directory
- The current file type
- The FTP reply code
- A buffer containing the FTP reply line sent to the client
- The FTP command code
- The current CONDDISP setting
- The file transfer completion code
- Name of the data set or z/OS UNIX file retrieved or stored
- Two words containing the bytes transferred during execution of this command
- The socket address structure of the client's control connection
- The socket address structure of the server's control connection
- A buffer containing the session instance identifier
- A 256-byte scratchpad buffer
- The one-byte description of the confidence level in successful completion of a transfer
- A buffer containing the FTP reply

The user exit can take action based on any of the information passed to it. The close reason code indicates whether the command completed successfully. The scratchpad buffer can be used to communicate information to other exits or the next instance of this exit.

The following parameter list is passed to FTPOSTPR:

Offset	Value
+0	Pointer to the fullword return code. The value is always 0 and is passed only for consistency with other FTP user exits and parameter lists.
+4	Pointer to a word containing the number of following parameters (17).
+8	Pointer to the 8-byte buffer containing the user ID.

+12

Pointer to the 4-byte client IP address. If the client's address is an IPv6 address, this field points to a word containing x'FFFFFFFF' and the passed socket address structure for the client must be used instead. If the client's address is an IPv4 address, either this field or the socket address structure can be used.

+16

Pointer to the 2-byte client port number. Valid only when the 4-byte client IP address is not x'FFFFFFFF'.

+20

Pointer to the 4-byte character string with current directory type: MVS or z/OS UNIX (left-aligned).

+24

Pointer to a buffer containing the current directory value. The first 2 bytes hold the length of the remaining buffer.

+28

Pointer to the 4-character byte field containing the current file type (SEQ, JES, SQL) left-aligned.

+32

Pointer to the 3-character byte field containing the current FTP reply code.

+36

Pointer to buffer containing the last line of the FTP reply that was sent to the client. The first 2 bytes contain the length of the remaining buffer. When the length is zero, it indicates that the reply could not be sent to the client.

+40

Pointer to the 4-byte field containing the current FTP command code.

+44

Pointer to the 1-character byte field containing the current CONDDISP setting: C for catalog, D for delete.

+48

Pointer to the 4-byte binary field with close reason code:

- 0 — Transfer completed normally.
- 4 — Transfer completed with errors; see FTP reply code and text string.
- 8 — Transfer completed with socket communication errors; transfer is ended and no response can be sent to client.
- 12 — Transfer aborted after data connection was established.
- 16 — Transfer aborted with SQL file errors after data connection was established.

+52

Pointer to a buffer containing the name of the data set or z/OS UNIX file just retrieved or stored. The first two bytes hold the length of the remainder, and the remainder of the buffer (up to 1023 bytes) holds any additional path specification beyond the current working directory and the file name.

+56

Pointer to two contiguous words containing the bytes transferred during execution of the current FTP command. The first word holds the number of gigabytes transferred. The second word holds the number of bytes transferred in addition to the number of gigabytes transferred. The number of bytes value (word 2) can be up to 4 gigabytes.

+60

Pointer to a copy of the socket address structure for the client's control connection. This area is mapped by the SOCKADDR DSECT found in the sample exit. The FAMILY field denotes whether the structure contains an IPv4 or an IPv6 address. When the family is AF_INET, the structure contains an IPv4 address. When the FAMILY is AF_INET6, you must inspect the address itself to determine whether it is an IPv6 address or an IPv4 mapped IPv6 address.

+64

Pointer to a copy of the socket address structure for the server's control connection. This area is mapped by the SOCKADDR DSECT found in the sample exit. The FAMILY field denotes whether the structure contains an IPv4 or an IPv6 address. When the family is AF_INET, the structure contains an IPv4 address. When the FAMILY is AF_INET6, you must inspect the address itself to determine whether it is an IPv6 address or an IPv4 mapped IPv6 address.

+68

Pointer to a buffer containing a 2-byte length followed by the session identifier created by the daemon when the connection was first established for this session. The identifier has a maximum length of 14 bytes and is unique within this instance of the server.

+72

Pointer to a 256-byte scratchpad buffer, which can be used to pass information between user exits. All exits receive a pointer to this buffer except FTCHKIP and FTCHKPWD. FTP does not query or alter the contents of the scratchpad at any time. The extended tracing (DUMP) identifier of the scratchpad is 87. If extended tracing of the scratchpad is requested, the contents are dumped after execution of the user exit.

+76

Pointer to a 1-byte description of the confidence level in successful completion of a transfer. Possible values are:

X'00'

Confidence level is High. No errors were detected on the inbound transfer

X'01'

Confidence level is NoEOF due to a missing EOF marker in an inbound file being transferred using STRUCTURE RECORD, MODE B, or MODE C.

X'02'

Confidence level is Low because the client did not respond after the inbound transfer or another error was reported. Low overrides NoEOF if both conditions are present.

X'03'

Confidence level is Unknown because this is an outbound transfer. An outbound transfer reports a confidence level of Low if an error occurs shutting down the data connection. Otherwise, outbound transfers are reported as Unknown even if no error was detected because not all checks can be done for outbound transfers

X'04'

Confidence level checking is not active. See [“CHKCONFIDENCE statement \(FTP client and server\) statement” on page 650.](#)

+80

Pointer to a buffer containing the complete text of the server reply that was sent to the client. The first two bytes contain the length of the remaining buffer.

When the length of the remaining buffer is 0, FTP could not obtain sufficient storage to hold the complete text of the server reply. You can obtain the last line of the reply by inspecting the parameter at offset x'36'.

The FTCHKIP user exit

FTCHKIP is called at the initial stage of login or whenever the user issues an OPEN command to open a new connection. The IP and PORT addresses of the local and remote hosts are passed to the user exit. The user exit can use them to determine whether the remote host's control connection should be canceled. The message 421 User Exit rejects open for connection is sent to the user if the connection is denied. The following parameter list is passed to FTCHKIP.

Offset**Value****+0**

Pointer to the word with the return code

+4

Pointer to a word containing the number of following parameters (7)

+8

Pointer to the fullword remote IP address. If the client's address is an IPv6 address, this field points to a word containing x'FFFFFFFF' and the passed socket address structure for the client must be used instead. If the client's address is an IPv4 address, either this field or the socket address structure can be used.

+12

Pointer to the halfword remote port number. Valid only when the fullword remote IP address is not x'FFFFFFFF'.

+16

Pointer to the fullword local IP address. If the server's address is an IPv6 address, this field points to a word containing x'FFFFFFFF' and the passed socket address structure for the server should be used instead. If the server's address is an IPv4 address, either this field or the socket address structure can be used.

+20

Pointer to the halfword local port number. Valid only when the fullword local IP address is not x'FFFFFFFF'.

+24

Pointer to a copy of the socket address structure for the client's control connection. This area is mapped by the SOCKADDR DSECT found in the sample exit. The FAMILY field denotes whether the structure contains an IPv4 or an IPv6 address. When the family is AF_INET, the structure contains an IPv4 address. When the FAMILY is AF_INET6, you must inspect the address itself to determine whether it is an IPv6 address or an IPv4 mapped IPv6 address.

+28

Pointer to a copy of the socket address structure for the server's control connection. This area is mapped by the SOCKADDR DSECT found in the sample exit. The FAMILY field denotes whether the structure contains an IPv4 or an IPv6 address. When the family is AF_INET, the structure contains an IPv4 address. When the FAMILY is AF_INET6, you must inspect the address itself to determine whether it is an IPv6 address or an IPv4 mapped IPv6 address.

+32

Pointer to a buffer containing a 2-byte length followed by the session identifier created by the daemon when the connection was first established for this session. The identifier has a maximum length of 14 bytes and is unique within this instance of the server.

FTCHKIP has been placed before the user logs in, and if access is denied, the user receives a message and the control connection is severed. This message comes at a point when most clients expect to continue with the login process by sending the user ID and password. Even though it is possible, some FTP clients might not expect a 421 message at this point, but it is the most appropriate place for this exit.

The FTCHKPWD user exit

The FTP server calls the FTCHKPWD exit after the server receives the user ID and password from the FTP client, but before the server uses the password to authenticate the user logging in. When the user logs in anonymously, and you have coded ANONYMOUSLEVEL 3 in the server's FTP.DATA, and the server prompts the user for an email address, the FTP server calls this exit:

- after the server receives the USER command,
- and again after it receives the PASS command.

The exit has the option of rejecting the attempt to log in to the FTP server. The reply Login attempt by '<user>' rejected by user exit is sent to the user if the exit rejects the request to log in to the FTP server. The following parameter list is passed to FTCHKPWD.

Offset

Value

+0

Pointer to the word with the return code

Requirement: The FTCHKPWD exit routine must set the return code to a nonzero value to reject the attempt to log in. The FTCHKPWD exit routine must set the return code to zero to permit the user to continue logging in.

+4

Pointer to a word containing the number of following parameters (8)

+8

Pointer to the 8-byte ID of the user logging in

+12

Pointer to the 8-byte password of the user logging in

Results:

- The password is passed without alteration to the exit routine when one of the following situations occurs:
 - You have enabled RACF mixed case password support
 - Your security product is not RACF, but it uses the RACF SAF interface to indicate that mixed passwords are enabled.

Otherwise, the password is translated to uppercase before it is passed to the exit routine.

- If the user logs in with a password phrase, this parameter is set to the first eight characters of the password phrase.

Tip: The password or entire password phrase is also passed to the exit as the parameter at offset +36.

+16

Pointer to a buffer containing a field that is 2 bytes in length followed by the user data

See [“ANONYMOUS \(FTP server\) statement” on page 630](#) for more information about this field.

+20

Pointer to a word containing the total number of bad passwords entered during this session

+24

Pointer to a copy of the socket address structure for the client's control connection. This area is mapped by the SOCKADDR DSECT found in the sample exit. The FAMILY field denotes whether the structure contains an IPv4 or an IPv6 address. When the family is AF_INET, the structure contains an IPv4 address. When the FAMILY is AF_INET6, you must inspect the address itself to determine whether it is an IPv6 address or an IPv4 mapped IPv6 address.

+28

Pointer to a copy of the socket address structure for the server's control connection. This area is mapped by the SOCKADDR DSECT found in the sample exit. The FAMILY field denotes whether the structure contains an IPv4 or an IPv6 address. When the family is AF_INET, the structure contains an IPv4 address. When the FAMILY is AF_INET6, you must inspect the address itself to determine whether it is an IPv6 address or an IPv4 mapped IPv6 address.

+32

Pointer to a buffer containing a field that is 2 bytes in length followed by the session identifier that was created by the daemon when the connection was first established for this session. The identifier has a maximum length of 14 bytes and is unique within this instance of the server.

+36

Pointer to a buffer containing a field that is 2 bytes in length followed by the password or password phrase the user entered to log in to the FTP server.

Notes:

- When PASSPHRASE FALSE is configured in FTP.DATA of the server, the pointed buffer consists of a 2-byte field, which contains zeros, and is followed by 100 blanks.

- When PASSPHRASE TRUE is configured in FTP.DATA of the server, the pointed buffer consists of a 2-byte field, which contains the length of the password or password phrase, and is followed by a 100-byte field. The 100-byte field contains the password or password phrase that is used to log in to FTP and is right-padded with blanks that are up to 100 characters in length.

The FTCHKJES user exit

FTCHKJES is called if the server is in FILETYPE=JES mode and the client tries to submit a job. The exit can allow or refuse the job to be submitted to the JES internal reader based on any criteria passed to the exit. For example, the exit can look for a USER= parameter on the JOB statement and check it against the client's user ID. The reply 550 User Exit refuses this job to be submitted by userid is sent to the user if the remote job submission is denied. The following parameter list is passed to FTCHKJES.

Offset

Value

+0

Pointer to the word with the return code

+4

Pointer to a word containing the number of following parameters (13)

+8

Pointer to the 8-character user ID that is logged on

+12

Pointer to the buffer containing the current logical record being submitted

+16

Pointer to a word with the number of bytes in the buffer

+20

Pointer to a word containing the JES LRECL being used

+24

Pointer to a word containing the logical record number

+28

Pointer to a word containing the total number of bytes transferred so far

+32

Pointer to a word containing the unique client ID

+36

Pointer to a word containing the JES RECFM (0 for fixed, 1 for variable)

+40

Pointer to a word containing the JES user exit anchor. (One possible use of this anchor is to provide the exit routine with a location to store the address of a persistent storage area for handling multiple calls.)

+44

Pointer to a copy of the socket address structure for the client's control connection. This area is mapped by the SOCKADDR DSECT found in the sample exit. The FAMILY field denotes whether the structure contains an IPv4 or an IPv6 address. When the family is AF_INET, the structure contains an IPv4 address. When the FAMILY is AF_INET6, you must inspect the address itself to determine whether it is an IPv6 address or an IPv4 mapped IPv6 address.

+48

Pointer to a copy of the socket address structure for the server's control connection. This area is mapped by the SOCKADDR DSECT found in the sample exit. The FAMILY field denotes whether the structure contains an IPv4 or an IPv6 address. When the family is AF_INET, the structure contains an IPv4 address. When the FAMILY is AF_INET6, you must inspect the address itself to determine whether it is an IPv6 address or an IPv4 mapped IPv6 address.

+52

Pointer to a buffer containing a 2-byte length followed by the session identifier created by the daemon when the connection was first established for this session. The identifier is unique within this instance of the daemon. It is included in messages written to SYSLOG and can be used similarly by the exit. It is preferred over the similar client ID found at +32 in the parameter list.

+56

Pointer to a 256-byte scratchpad buffer, which can be used to pass information between user exits. All exits receive a pointer to this buffer, except FTCHKIP and FTCHKPWD. FTP does not query or alter the contents of the scratchpad at any time. The extended tracing (DUMP) identifier of the scratchpad is 87. If extended tracing of the scratchpad is requested, the contents are dumped after execution of the user exit.

The return code word is initialized to 0 so the user exit can return without changing it if there is a correct return code. Any other return code denies access to the resource in question.

The FTP server SMF user exit

To access the (preferred) type 119 FTP SMF records, use the system-wide SMF user exits IEFU83 and IEFU85. See *z/OS MVS System Management Facilities (SMF)* for more information. For the FTP client, IEFU85 SMF exit is invoked, and for the FTP server, IEFU83 SMF exit is invoked.

Restriction: This exit is called for type 118 records only.

Tip: Some FTP type 119 records are available to the NMI SYSTCPSM programming interface. See the information about real time SMF data NMI (SYSTCPSM) record formats in *z/OS Communications Server: IP Programmer's Guide and Reference*.

Type 118 SMF record types to be written are based on the SMFCONFIG statement in SMF.DATA. The FTP server SMF user exit is called before a matching type 118 SMF record is written to the SYS1.MANx data set. The user exit allows site-specific modifications to the record and can prevent the record's being written to the SYS1.MANx data set.

To enable the exit, include the SMFEXIT statement in the FTP.DATA data set.

Requirement: The routine must be named FTPSMFEX and placed in an installation-defined link library or an APF-authorized data set defined by a STEPLIB DD statement in the FTPD cataloged procedure. FTP calls the SMF user exit before each type 118 SMF record is written.

On entry to FTPSMFEX, register 1 contains a pointer to the following 2-word parameter list:

Offset

Value

0

Pointer to the return code

4

Pointer to the type 118 SMF record

Prior to calling the SMF user exit, the return code is set to 0. A return code of 0 specifies that the SMF record is written. To suppress writing the SMF record to the SYS1.MANx data set, the user exit must change the return code to a nonzero value.

FTP client user exits

The FTP client uses user exits to provide security to enable the administrator to control the FTP commands that are sent to the server or to monitor replies that are sent from the FTP server. For example, an administrator can perform the following actions:

- Protect some data sets, which a user has access to, from being transferred from the z/OS host.
- Inspect or modify the names of data sets that are specified on file transfer subcommands by end users.
- End an FTP client address space, if that client is in the process of sending an unauthorized FTP command.

- Inspect each reply from the FTP server and, if certain replies are received, end the client.

Restrictions:

- User exit routines must be in a cataloged data set which is APF-authorized. The data set must be made available to the FTP client via standard z/OS load module search, such as adding the data set to the LNKLIST or via STEPLIB.
- User exit routines must be reentrant.
- User exit routines should be written in Assembler Language. Standard linkage conventions must be used. See [z/OS MVS Programming: Assembler Services Guide](#) for the linkage conventions.

Restriction: User exit routines can be written in C, but C exit routines cannot return an exit reason code. If necessary, you can return a message in the optional message field to display the reason code.

- User exit routines are invoked in TCB mode, program problem state, with AMODE(31). If the user exit routine changes a setting, it must restore it before returning to the caller.
- User exit routines must communicate the result of their processing back to FTP client by setting a return code in register 15 and a reason code in register 0 (in case of a non-zero return code) before returning to the caller.
- FTP client user exits are not supported when the FTP client is invoked in an environment in which the FTP client cannot be executed as an authorized program or command. For example, FTP client user exits are not supported in the dynamic TSO environment that the IKJTSOEV service builds.

The parameter list that is passed to the user exit routine is an array of pointers to values. The first word of the parameter list points to a word that contains the number of parameters that follow. This helps you to handle any future releases that might increase the number of parameters in these parameter lists. The FTP client passes the TCP connection ID to each user exit. The TCP connection ID parameter uniquely identifies a control connection, and remains the same for all user exit calls that are associated with a specific control connection. You can use the TCP connection ID to correlate user exit calls.

To install your user exit routines, associate them with the defined user exit by using either of these methods:

- The EXIT statement of the PROGxx parmlib member. The EXIT statement allows an installation to add exit routines to an exit. At IPL, you can use PROG=xx to specify the particular PROGxx parmlib member that the system is to use. For example, you can specify:

```
EXIT ADD EXITNAME(EZAFCCMD) MODNAME(CSFTPEX1)
```

- The SETPROG EXIT operator command. This command performs the same functions as the EXIT statement of the PROGxx parmlib member. For example, you can specify:

```
SETPROG EXIT, ADD, EXITNAME=EZAFCCMD, MODNAME=CSFTPEX1
```

For more information about user exits installation, see [Exit Routines - Using Dynamic Exit Services in z/OS MVS Programming: Authorized Assembler Services Guide](#).

Dynamic exit services (DES) allows multiple exit routines to be run when a user exit is called. Multiple user exit routines mean that an exit routine called earlier in the sequence can end the client or the current command before the remaining exit routines are called. In that case, no remaining exit routines are called.

Multiple exit routines also mean that another exit routine might modify your output before the FTP client can apply it, and might modify the input from the FTP client before your exit routine receives it. Use caution when creating tokens or handles based on input parameters to avoid conflicts with other user exit routines.

Restriction: FTP cannot control the call sequence of the multiple exit routines. Do not assume your exit routine is called in any particular sequence, such as first or last.

See the detailed information about the following user exits:

- [“The EZAFCCMD user exit” on page 601](#)
- [“The EZAFCREP user exit” on page 607](#)

- [“Using both EZAFCMD and EZAFCREP user exits” on page 609](#)

Sample client user exits

You can find user exit samples in *hlq.SEZAINST(EZAFCEXT)*. EZAFCEXT is a JCL file. It creates user exit routine load modules. When the JCL is submitted, it creates four load modules. EZAFCMD and EZAFCREP are user exit routines. EZAFCOM and ASMTSYSL are assistant load modules that are called by the EZAFCMD and EZAFCREP user exit routines.

Table 41. User exit samples		
Load module	Language	Description
EZAFCMD	Assembler	EZAFCMD works in conjunction with the EZAFCREP. These two exits maintain a shared storage area where the FTP session state is maintained. The EZAFCMD maintains information in the shared session data area based on which commands are being sent to the server. When a file transfer has completed successfully, a message is written to syslogD.
EZAFCREP	Assembler	EZAFCREP works in conjunction with the EZAFCMD. These two exits maintain a shared storage area where the FTP session state is maintained. EZAFCREP analyzes the replies to the commands that were sent to the server and parses information from a select set of replies. When a file transfer has completed successfully, a message is written to syslogD.
EZAFCOM	Assembler	EZAFCOM is called from both of these exits during initialization. EZAFCOM contains common code for the EZAFCMD (EZAFCMD) and EZAFCREP (EZAFCREP) FTP client exit routines.
ASMTSYSL	Assembler	ASMTSYSL provides an interface for writing messages to z/OS syslogD from non-C programs.

The EZAFCMD user exit

The EZAFCMD user exit is called by the FTP client before each command is sent to the FTP server. It can be used to inspect an FTP command, modify the arguments of an FTP command, reject an FTP command, or end the FTP client before the command is sent to the server.

The following table is the parameter list that is passed to the EZAFCMD user exit:

Table 42. Parameter list passed to the EZAFCMD user exit	
+ Offset (decimal)	Value
0	Pointer to a binary fullword that contains the number of parameters that follow (15).
4	Pointer to the 8-byte TCP connection ID. This is a character field. The TCP connection ID parameter identifies a control connection, and remains the same for all user exit calls that are associated with a specific control connection.
8	Pointer to a 256-byte buffer that contains a 2-byte field followed by the remote FTP user ID. The first two bytes hold the length of the remote FTP user ID. The buffer is padded with NULLs.
12	Pointer to an 8-byte buffer that contains the FTP command that is being sent to the server. The buffer is padded with blanks.
16	Pointer to a 5122-byte buffer that contains a 2-byte field followed by the arguments of the FTP command reported at offset 12. The first two bytes hold the length of the FTP command arguments. This buffer is padded with NULLs.

Table 42. Parameter list passed to the EZAFCCMD user exit (continued)

+ Offset (decimal)	Value
20	Pointer to a 4-byte character string with the current local FTP client directory type: MVS or z/OS UNIX file system (left-aligned). The buffer is padded with blanks.
24	Pointer to a 4-byte character string with the local UNIX file type: FILE or FIFO. The buffer is padded with blanks.
28	Pointer to a 1026-byte buffer that contains a 2-byte field followed by the current local directory. The first two bytes of the buffer hold the length of the current local directory. The buffer is padded with NULLs.
32	Pointer to a 1026-byte buffer that contains a 2-byte field followed by the fully qualified local MVS data set name or the absolute path name of the local z/OS UNIX file. The first two bytes hold the length of the MVS data set name or path name. The value of the length is set to zero when the command is not associated with a local MVS data set name or z/OS UNIX file.

Table 42. Parameter list passed to the EZAFCCMD user exit (continued)

+ Offset (decimal)	Value
36	<p>Pointer to a 2-byte length field followed by a buffer containing the local FTP client configuration options (See note 1 following this table). The length field is set to the length of the buffer that follows. The configuration options come from the z/OS FTP client default configuration, the z/OS FTP client START parameters, and the z/OS FTP client FTP.DATA file or data set. Data in the buffer is in the format of <i>2-byte binary total length2-byte binary lengthconfig_option = config_value</i>, and is printable EBCDIC apart from the length field. The 2-byte length field does not include the length field itself. When you reach a length field with the value zero, there are no more entries in the buffer. The buffer is updated when a configuration option is changed by the following subcommands:</p> <ul style="list-style-type: none"> • LOCSITE • MODE • TYPE • STRUCT • ASCII • BIG5 • BINARY • BLOCK • EBCDIC • EUCKANJI • HANGEUL • IBMKANJI • JIS78KJ • JIS83KJ • KSC5601 • SCHINESE • TCHINESE • UCS2 • SJISKANJI • STREAM • RECORD • STRUCTURE • CCC • PROTECT • PROTECT • SAFE • CLEAR • PRIVATE <p>Requirement: Do not assume that a specific configuration option is always located at the same offset in this buffer. You must scan the buffer on each call to your exit routine to locate the specific option you are interested in.</p>

Table 42. Parameter list passed to the EZAFCCMD user exit (continued)

+ Offset (decimal)	Value
40	<p>Pointer to a copy of the socket address structure for the client control connection. This area is mapped by the SOCKADDR DSECT (See note 2 following this table).</p> <p>The FAMILY field denotes whether the structure contains an IPv4 (Family=2, AF_INET) or an IPv6 (Family=19, AF_INET6) address. When the family is AF_INET, the structure contains an IPv4 address. When the FAMILY is AF_INET6, you must inspect the address to determine whether it is an IPv6 address or an IPv4 mapped IPv6 address. See note 2 following this table for a sample layout of the socket address structure.</p>
44	<p>Pointer to a copy of the socket address structure for the server control connection. This area is mapped by the SOCKADDR DSECT (See note 2 following this table).</p> <p>The FAMILY field denotes whether the structure contains an IPv4 (Family=2, AF_INET) or an IPv6 (Family=19, AF_INET6) address. When the family is AF_INET, the structure contains an IPv4 address. When the FAMILY is AF_INET6, you must inspect the address to determine whether it is an IPv6 address or an IPv4 mapped IPv6 address. See note 2 following this table for a sample layout of the socket address structure.</p>
48	<p>Pointer to a copy of the socket address structure for the SOCKS server connection when the client connects to the FTP server through a SOCKS server. This area is mapped by the SOCKADDR DSECT (See note 2 following this table). If no SOCKS server is used, the first two bytes of the address structure will be set to X'0000'. The SOCKS server IP address is in the AF_INET address family.</p>
52	<p>Pointer to a 40-byte buffer containing the socket APPLDATA for the current control connection</p> <p>The FTP client APPLDATA for the control connection contains security related information for the control connection. For more information about APPLDATA, see FTP Client Application Programming Interface (API) in z/OS Communications Server: IP Programmer's Guide and Reference.</p>
56	<p>Pointer to a 5122-byte output buffer to return modified command arguments. Your exit routine can modify the arguments that are passed to the command by placing the modified arguments in this buffer. The first two bytes must be initialized to the length of the modified command arguments.</p>
60	<p>Pointer to a 71-byte buffer to return a message when the user exit routine ends the FTP client or rejects a command. Your exit routine can place text in this buffer to explain why it ended the FTP client or rejected the command. This buffer is initialized to the blanks before each call to the EZAFCCMD user exit.</p>

Note:

1. The following sample illustrates how the local configuration options structure is built:

```
H'16',C'OPTION1 = VALUE1',H'18',C'OPTION2 = VALUE234',,,,H'0'
```

```
2-bytes binary with the value 16, followed by a 16-byte character string
2-bytes binary with the value 18, followed by an 18-byte character string
2-byte binary with the value zero (no more options in the structure)
```

All entries use a common format with the option name followed by a space, followed by an equal sign (=), followed by another space, followed by the value of the option.

2. Sample socket address structure layout (based upon the SOCKADDR structure in SYS1.MACLIB(BPXYSOCK):

```

*
* -----
*
* Socket address structure
*
* -----
*
SOCKADDR DSECT
SOCKLEN  DC      AL1(0)          *If FAM=2, this field is zero
*                                *If FAM=19, this field is the
*                                *length of the structure
SOCKFAM  DC      AL1(0)          *Socket family
SOCKIPV4 EQU     2              *IPv4 socket structure
SOCKIPV6 EQU     19             *IPv6 socket structure
SOCKPORT DC      AL2(0)          *Port number
IPV4SOCK DS      0C
IPV4ADDR DC      A(0)           *IPv4 address
          ORG     IPV4SOCK
IPV6FLOW DC      A(0)           *IPv6 flow label
IPV6ADDR DC      XL16'00'       *IPv6 address
          ORG

```

The EZAFCMD user exit can return the following return codes to the FTP client in register 15:

RC=0

The exit is to send the command to server.

RC=4

The exit accepts the command but modifies the arguments.

RC=8

The exit rejects the command.

RC=12

The exit is to end the FTP client address space.

The EZAFCMD user exit can also return a reason code to the FTP client in register 0 if the return code in register 15 is not 0.

Results

- When user exit EZAFCMD returns code 0, FTP continues processing the command.
- When user exit EZAFCMD returns code 4,
 - If the arguments of the FTP command are modified, message EZA1532I is displayed.
 - The commands PASS and ACCT have security sensitive data in the command arguments and the arguments are not passed to the user exit. However, the exit is allowed to replace the arguments of the commands.
 - The command ADAT has security sensitive data in the command argument and the argument is not passed to the user exit. Message EZA1545I indicates that the modified argument will be ignored.
 - Because the FTP server and client must remain synchronized, changing the arguments of the following commands leads to unpredictable results:
 - AUTH
 - EPRT
 - EPSV
 - MODE
 - PBSZ
 - PORT
 - PROT
 - REST
 - SITE
 - STRU

- TYPE
- XLMT
- RETR during a load module transfer
- STOR during a load module transfer

Therefore, the changed arguments of these commands are ignored and an EZA1545I message is displayed.

- If more than one exit routine is associated with this user exit, the FTP client passes the modified arguments to the next user exit routine. If this is the only exit routine associated with this user exit, or it is the last exit routine in the calling sequence for this user exit, the FTP client sends the command with modified arguments to the server.
- When user exit EZAFCMD returns code 8,
 - FTP logs the reason code in register 0 with message EZA1533I, but does not interpret the reason code. The exit routine determines what the reason codes means.
 - If the exit routine returned a message in the 71-byte buffer provided at offset 64 in the EZAFCMD parameter list, the FTP client displays message EZA1556I before message EZA1533I to explain why the user exit routine rejected the command. The client always displays message EZA1533I.
 - The exit cannot reject the QUIT command, no matter whether the QUIT command is from the QUIT subcommand or from the CLOSE subcommand.
 - If more than one exit routine is associated with this user exit, the FTP client stops calling exit routines for this command.
- When user exit EZAFCMD returns code 12,
 - FTP logs the reason code in register 0 with message EZA1546I, but does not interpret the reason code. The exit routine determines what the reason codes means.
 - If the exit routine returned a message in the 71-byte buffer provided at offset 64 in the EZAFCMD parameter list, the client displays message EZA1556I before message EZA1546I to explain why the user exit routine ended the FTP client. The client always displays message EZA1556I.
 - The exit cannot end the FTP client when the QUIT command is from the QUIT subcommand. However, the client always ends as part of QUIT subcommand processing.
 - The exit can end the FTP client when the QUIT command is from the CLOSE subcommand.
 - If more than one exit routine is associated with this user exit, the FTP client stops calling exit routines for this command.

Examples

Example 1: If the EZAFCMD1 user exit routine is installed for the EZAFCMD user exit, EZAFCMD1 modifies the argument of the CWD command to '/u/user1':

```
EZA1460I Command:
cd 'user1'
EZA1532I User exit EZAFCMD module EZAFCMD1 modified the FTP command arguments
EZA1701I >>> CWD /u/user1
250 HFS directory /u/user1 is the current working directory.
```

Example 2: If the EZAFCMD2 user exit routine is installed for the EZAFCMD user exit, EZAFCMD2 rejects the PORT command:

```
EZA1460I Command:
ls
EZA1556I EZAFCMD message: EZAFCMD2 Rejected the FTP command
EZA1533I User exit EZAFCMD module EZAFCMD2 prevented user USER1 from sending co
mmand PORT - exit reason code x'00000004' (4)
EZA1636I *** I can't open a data-transfer connection:
EZZ9830I USER13 FTP failed - Cmd = 20(ls) Reply = n/a NX CEE RC = 2720
```

Example 3: If the EZAFCM3 user exit routine is installed for the EZAFCMD user exit, EZAFCM3 ends the FTP client:

```
EZA1460I Command:
get '/u/user1/ftp.example' '/u/user2/ftp.example'
EZA1556I EZAFCMD message: EZAFCM3 cancelled the FTP client
EZA1546I User exit EZAFCMD module EZAFCM3 ended the FTP client - exit reason c
ode x'00000004' (4)
EZA1636I *** I can't open a data-transfer connection:
EZA1701I >>> QUIT
221 Quit command received. Goodbye.
```

Example 4: Multiple user exit routines can be installed for the EZAFCMD user exit. The EZAFCM4 and EZAFCM5 user exit routines are installed for the EZAFCMD user exit. EZAFCM4 modifies the argument of the LIST command to '/u/user2' and EZAFCM5 ends the FTP client when it receives the LIST command:

```
EZA1460I Command:
dir '/u/user1'
EZA1701I >>> PORT 9,42,105,183,4,31
200 Port request OK.
EZA1532I User exit EZAFCMD module EZAFCM4 modified the FTP command arguments
EZA1556I EZAFCMD message: EZAFCM5 cancelled the FTP client
EZA1546I User exit EZAFCMD module EZAFCM5 ended the FTP client - exit reason c
ode x'00000004' (4)
EZZ9830I USER11 FTP failed - Cmd = 14(dir) Reply = 200 NX CEE RC = 2814
EZA1701I >>> QUIT
221 Quit command received. Goodbye.
```

The EZAFCREP user exit

The EZAFCREP user exit is called when the FTP client receives a single-line reply or one line of a multiple line reply over the control connection that is sent from the server. A user exit routine that you write for EZAFCREP can inspect the FTP server reply, or end the FTP client after the FTP client receives a certain line of the reply sent from the server.

The following table is the parameter list that is passed to the EZAFCREP user exit:

Table 43. Parameter list passed to the EZAFCREP user exit	
+ Offset (decimal)	Value
0	Pointer to a binary fullword that contains the number of parameters that follow (4).
4	Pointer to the 8-byte TCP connection ID. This is a character field. The TCP connection ID parameter uniquely identifies a control connection, and will remain the same for all user exit calls that are associated with a specific control connection.
8	Pointer to a buffer that contains a 2-byte length field followed by the FTP server reply line. The first two bytes hold the length of FTP server reply line. The buffer is padded with NULLs.
12	Pointer to a 40-byte buffer containing the socket APPLDATA for the current control connection. For more information about APPLDATA, see FTP Client Application Programming Interface (API) in z/OS Communications Server: IP Programmer's Guide and Reference .
16	Pointer to a 71-byte buffer to return a message when the user exit routine ends the FTP client. The user exit can put text in this buffer to explain why it ends the FTP client. If the exit supplies text in this buffer, the FTP client displays this text as message EZZ1556I. This buffer is initialized to blanks before each call to the EZAFCREP user exit.

The EZAFCREP user exit can return the following return codes to the FTP client in register 15:

RC=0

The exit accepts the reply.

RC=12

The exit ends the FTP client address space.

It can also return a reason code to the FTP client in register 0 if the return code in register 15 is not 0.

Results

- When the EZAFCREP user exit returns code 0, FTP continues processing the reply.
- When the EZAFCREP user exit returns code 12,
 - FTP logs the reason code in register 0 with message EZA1546I, but does not interpret the reason code. The exit routine determines what the reason codes means.
 - If the exit routine places a message into the 71-byte buffer, the client displays it as message EZA1556I before message EZA1546I. The client always displays message EZA1556I.
 - If the input to the EZAFCREP user exit was one line of a multiple line reply, FTP flushes the remaining lines of the reply from its receive buffer, but does not print them.
 - The FTP client ignores the return code if the EZAFCREP user exit decides to end the FTP client for a reply to the QUIT command.
 - The FTP client ignores the return code if the EZAFCREP user exit decides to end the FTP client for a reply with the reply code in the range 100 - 199.

Example

If the user exit EZAFCREP is active, it is called for each line of a reply as it is received, and FTP displays each line of reply as it is received. If the user exit ends the FTP client in the middle of a multiple line reply, the FTP client will flush all remaining lines of the reply but not print them. The user exit will not be called again for this instance of the FTP client.

Suppose two user exit routines EZAFCRE1 and EZAFCRE2 are both installed for user exit EZAFCREP. EZAFCRE1 ends the FTP client when it receives the reply '214 - A fully qualified directory name (specified in quotes or' from subcommand help server cwd, EZAFCRE2 accepts any FTP reply. Suppose the operator installs the two exit routines in this order: first EZAFCRE1, then EZAFCRE2.

```
help server cwd
EZA1701I >>> HELP CWD
EZA1582I The foreign server has this help:
214-CWD directory-name: changes the working directory to this directory-name
214-by appending it to the present working directory name.
214-A fully qualified directory name (specified in quotes or
EZA1556I EZAFCREP message: EZAFCRE1 Cancelled the FTP client
EZA1546I User exit EZAFCREP module EZAFCRE1 ended the FTP client - exit reason c
ode x'00000001' (1)
EZA1701I >>> QUIT
221 Quit command received. Goodbye.
```

```
The log on the system console:
- 00.07.42 EZAFCRE1 - Input - Offset: +00 Value: 00000003
- 00.07.42 EZAFCRE1 - Input - Offset: +04 Value: 00000088
- 00.07.42 EZAFCRE1 - Input - Offset: +08 Value: 214-CWD directory-
- name: changes the working directory to this directory-name
- 00.07.42 EZAFCRE2 - Input - Offset: +00 Value: 00000003
- 00.07.42 EZAFCRE2 - Input - Offset: +04 Value: 00000088
- 00.07.42 EZAFCRE2 - Input - Offset: +08 Value: 214-CWD directory-
- name: changes the working directory to this directory-name
- 00.07.42 EZAFCRE1 - Input - Offset: +00 Value: 00000003
- 00.07.42 EZAFCRE1 - Input - Offset: +04 Value: 00000088
- 00.07.42 EZAFCRE1 - Input - Offset: +08 Value: 214-by appending it
- to the present working directory
name.
- 00.07.42 EZAFCRE2 - Input - Offset: +00 Value: 00000003
- 00.07.42 EZAFCRE2 - Input - Offset: +04 Value: 00000088
```

```
- 00.07.42 EZAFCRE2 - Input - Offset: +08 Value: 214-by appending it
- to the present working directory name.
- 00.07.42 EZAFCRE1 - Input - Offset: +00 Value: 00000003
- 00.07.42 EZAFCRE1 - Input - Offset: +04 Value: 00000088
- 00.07.42 EZAFCRE1 - Input - Offset: +08 Value: 214-A fully qualified
- directory name (specified in quotes or
```

In this example, the EZAFCRE1 user exit routine is called three times and the EZAFCRE2 user exit routine is called two times. If EZAFCRE1 ends the FTP client for a certain reply:

- EZAFCRE2 will not be called again for this invocation of EZAFCREP.
- EZAFCREP will not be called again for this FTP client.

The FTP client will flush remaining reply lines from command HELP CWD. The FTP client sends a QUIT command to the server.

Using both EZAFCMD and EZAFCREP user exits

Results:

- Usually a call to user exit EZAFCMD will have a corresponding call to user exit EZAFCREP, but not in the following situations:
 - If the EZAFCMD user exit decides to reject the command or end the FTP client, the command will not be sent to the server, so the EZAFCREP user exit will not be called.
 - You can install more than one EZAFCREP exit routine. If one of the exit routines decides to end the client, the remaining EZAFCREP exit routines will not be called for the corresponding EZAFCMD call.
- Usually a call to the EZAFCREP user exit will have a corresponding call to user exit EZAFCMD, but not when the FTP server sends the Good Morning reply 220 to the client before the first command flows to the server from the client. The EZAFCREP user exit is called, but there is no corresponding EZAFCMD call.

Requirements:

- Your EZAFCMD exit routine must handle the possibility that your EZAFCREP exit routine will not be called.
- Your EZAFCREP exit routine must handle the possibility that your EZAFCMD exit was not called.

FTP configuration statements in FTP.DATA

The FTP.DATA configuration data set is optional. The FTP daemon searches for this data set during initialization.

The FTP server search order is:

1. A data set specified by the //SYSFTPDD statement
2. *ftpserve_job_name*.FTP.DATA
3. /etc/ftp.data
4. SYS1.TCPPARMS(FTPDATA)
5. *hlq*.FTP.DATA data set

As shown in [Table 44 on page 610](#), the FTP client uses one of the following search orders to obtain the local site parameter values:

Table 44. FTP client search orders

TSO shell	UNIX System Services shell
1. -f	1. -f
2. SYSFTPD DD statement	2. \$HOME/ftp.data
3. tso_prefix.FTP.DATA	3. userid.FTP.DATA
4. userid.FTP.DATA	4. /etc/ftp.data
5. /etc/ftp.data	5. SYS1.TCPPARMS(FTPDATA) data set
6. SYS1.TCPPARMS(FTPDATA) data set	6. tcpip_hlq.FTP.DATA file
7. tcpip_hlq.FTP.DATA file	

If you use an MVS data set, this data set should have a logical record length of 80 and a block size that is a multiple of 80. If a UNIX file (such as /etc/ftp.data) is the configuration input, ensure that there are no trailing blanks on the configuration statements, because some specifications might be rejected if trailing blanks are present.

FTP parameters have default values, and you can change these defaults using statements in the FTP.DATA configuration data set. It is not necessary to include all statements in the FTP.DATA data set.

Guideline: Only include the statements if the default value is not what you want, because the default is used for any statement not included in the FTP.DATA data set.

The following names are shipped samples of the FTP.DATA data sets:

- SEZAINST(FTPDATA) for the server
- SEZAINST(FTCDATA) for the client

The FTP client and server read FTP.DATA once at initialization. Therefore, any changes you make to FTP.DATA are not applied until the next time you start the FTP client and server.

Some FTP server parameters can be changed during an FTP session by issuing the SITE command from the FTP client. Likewise, FTP client parameters can be changed during an FTP session by issuing the subcommand from the FTP client. See the [z/OS Communications Server: IP User's Guide and Commands](#) for more information about the SITE command and the [LOCSite subcommand--Specify site information to the local host subcommand](#).

Data set attributes play a significant role in FTP performance.

Guidelines: If your environment permits, tune both BLKSIZE and LRECL according to the following guidelines:

- Use a value at or slightly below half of a DASD track as the block size. The half-track threshold for IBM 3380 DASD is 23 476 and for IBM 3390 DASD is 27 998.
- Use FB as the data set allocation format.
- Use cached DASD controllers.
- If your environment permits, use a preallocated data set for FTP transfer operations into MVS.

Summary of FTP client and server configuration statements

The statements for the FTP.DATA data set are summarized in [Table 45 on page 611](#) and explained in detail in [“FTP.DATA data set statements” on page 628](#).

Guidelines:

- Use separate FTP.DATA data sets for the FTP client and the FTP server if you are specifying any conflicting statements.
- When you share the FTP server FTP.DATA data set with the FTP client, understand that some of the values for the statements in the FTP.DATA data set have different meanings in the two environments. If

the files are shared, error messages could be generated or values that are not valid could be used for each client using the FTP.DATA data set containing server-only statements.

See [“FTP configuration statements in FTP.DATA” on page 609](#) for more information about the search order for both the client and server.

Table 45. Summary of FTP client and server configuration statements

Statement	Description	Applies to client, server, or both	See
ACCESSERRORMSG	Allow FTP Server to send detailed login failure replies.	Server	“ACCESSERRORMSG (FTP server) statement” on page 628
ADMINEMAILADDRESS	Specify a value to use with %E keyword for banner text.	Server	“ADMINEMAILADDRESS (FTP server) statement” on page 629
ANONYMOUS	Allow a remote user to issue USER ANONYMOUS without supplying a logon password.	Server	“ANONYMOUS (FTP server) statement” on page 630
ANONYMOUSFILEACCESS	Specify the type of files (MVS or z/OS UNIX) that anonymous clients are allowed to access.	Server	“ANONYMOUSFILEACCESS (FTP server) statement” on page 632
ANONYMOUSFILETYPEJES	Control access to the FILETYPE SITE keyword of anonymous users when ANONYMOUSLEVEL 3 or greater is specified.	Server	“ANONYMOUSFILETYPEJES (FTP server) statement” on page 633
ANONYMOUSFILETYPESEQ	Control access to the FILETYPE SITE keyword of anonymous users when ANONYMOUSLEVEL 3 or greater is specified.	Server	“ANONYMOUSFILETYPESEQ (FTP server) statement” on page 633
ANONYMOUSFILETYPESQL	Control access to the FILETYPE SITE keyword of anonymous users when ANONYMOUSLEVEL 3 or greater is specified.	Server	“ANONYMOUSFILETYPESQL (FTP server) statement” on page 634
ANONYMOUSFTPLOGGING	Specify whether the FTP server should log FTP session activity for anonymous users.	Server	“ANONYMOUSFTPLOGGING (FTP server) statement” on page 635
ANONYMOUSHFSDIRMODE	Specify the mode bits used for directories created by anonymous users.	Server	“ANONYMOUSHFSDIRMODE (FTP server) statement” on page 636

Table 45. Summary of FTP client and server configuration statements (continued)

Statement	Description	Applies to client, server, or both	See
ANONYMOUSHFSFILEMODE	Specify the mode bits used when storing files created by anonymous users.	Server	“ANONYMOUSHFSFILEMODE (FTP server) statement” on page 637
ANONYMOUSHFSINFO	Specify an anonymous user z/OS UNIX directory information file mask.	Server	“ANONYMOUSHFSINFO (FTP server) statement” on page 637
ANONYMOUSLEVEL	Specify the type of anonymous access permitted to users who issue USER ANONYMOUS.	Server	“ANONYMOUSLEVEL (FTP server) statement” on page 638
ANONYMOUSLOGINMSG	Specify anonymous user login messages.	Server	“ANONYMOUSLOGINMSG (FTP server) statement” on page 640
ANONYMOUSMVSINFO	Specify anonymous user MVS information file (LLQ).	Server	“ANONYMOUSMVSINFO (FTP server) statement” on page 642
APPLNAME	Specify the FTP server application name.	Server	“APPLNAME (FTP server) statement” on page 643
ASATRANS	Specify how print control characters should be handled.	Both	“ASATRANS (FTP client and server) statement” on page 643
AUTOMOUNT	Specify whether to mount DASD volumes containing data sets to be accessed.	Both	“AUTOMOUNT (FTP client and server) statement” on page 644
AUTORECALL	Automatically recall data sets migrated by the storage manager.	Both	“AUTORECALL (FTP client and server) statement” on page 644
AUTOTAPEMOUNT	Specify whether to mount tape volumes containing data sets to be accessed.	Both	“AUTOTAPEMOUNT (FTP client and server) statement” on page 645
BANNER	Request that a welcome banner is displayed immediately after a new connection is established.	Server	“BANNER (FTP server) statement” on page 646
BLKSIZE	Specify the block size of newly allocated data sets.	Both	“BLKSIZE (FTP client and server) statement” on page 647
BUFNO	Specify the number of access method buffers.	Both	“BUFNO (FTP client and server) statement” on page 648

Table 45. Summary of FTP client and server configuration statements (continued)

Statement	Description	Applies to client, server, or both	See
CCONNTIME	Defines the amount of time to wait after attempting to close a control connection before terminating it and reporting an error.	Client	“CCONNTIME (FTP client) statement” on page 648
CCTTRANS	Specify the SBCS translation table to be used for the control connection.	Client	“CCTTRANS (FTP client) statement” on page 649
CCXLATE	Specify the translation table data set for the control connection.	Server	“CCXLATE (FTP server) statement” on page 649
CHKCONFIDENCE	Specify that the FTP client or server checks and reports the confidence level in the successful completion of file transfers.	Both	“CHKCONFIDENCE statement (FTP client and server) statement” on page 650
CHKPTINT	Specify the checkpoint interval when FTP is the sending site in a file transfer request.	Both	“CHKPTINT (FTP client and server) statement” on page 652
CHKPTPREFIX	Used to determine the <i>hlq</i> for the checkpoint file.	Client	“CHKPTPREFIX (FTP client) statement” on page 654
CIPHERSUITE	Specify the name of a CipherSuite that is used during the TLS handshake.	Client	“CIPHERSUITE (FTP client) statement” on page 655
CLIENTERRCODES	Specify whether FTP return codes are to be converted to client error codes.	Client	“CLIENTERRCODES (FTP client) statement” on page 657
CONDDISP	Specify whether FTP should keep or delete a new data set or file when a file transfer ends prematurely.	Both	“CONDDISP (FTP client and server) statement” on page 658

Table 45. Summary of FTP client and server configuration statements (continued)

Statement	Description	Applies to client, server, or both	See
CTRL_TLS_SESSTCKTS	Use the CTRL_TLS_SESSTCKTS statement to specify whether the FTP server should control the sending of TLSv1.3 session tickets for session reuse or allow session tickets to be sent transparently by AT-TLS.	Server	“CTRL_TLS_SESSTCKTS (FTP server) statement” on page 659
CTRLCONN	Specify code set to be used for the control connection.	Both	“CTRLCONN (FTP client and server) statement” on page 660
DATACLASS	Specify the SMS-managed data class as defined by your organization for FTP.	Both	“DATACLASS (FTP client and server) statement” on page 661
DATACTTIME	Specify the amount time that the client waits after attempting to send or receive data before terminating the connection and reporting an error to the user.	Client	“DATACTTIME (FTP client) statement” on page 663
DATAKEEPAIVE	Specify the data connection keepalive timer.	Both	“DATAKEEPAIVE (FTP client and server) statement” on page 664
DATATIMEOUT	Specify the time that the server waits for a response to a send or for the completion of a passive connection.	Server	“DATATIMEOUT (FTP server) statement” on page 664
DB2®	Specify the name of the Db2 subsystem.	Both	“DB2 (FTP client and server) statement” on page 665
DB2PLAN	Specify the name of the Db2 plan to be used by FTP.	Both	“DB2PLAN (FTP client and server) statement” on page 666
DBSUB	Specify whether substitution is allowed for double-byte file data that cannot be translated.	Both	“DBSUB (FTP client and server) statement” on page 666

Table 45. Summary of FTP client and server configuration statements (continued)

Statement	Description	Applies to client, server, or both	See
DCBDSN	Specify a data set to be used as a model for allocation of new data sets.	Both	“DCBDSN (FTP client and server) statement” on page 667
DCONNTIME	Specify the amount of time to wait after attempting to close a data transfer before terminating the connection and reporting an error.	Both	“DCONNTIME (FTP client and server) statement” on page 668
DEBUG	Specify to activate a specific trace type.	Both	“DEBUG (FTP client and server) statement” on page 668
DEBUGONSITE	Specify whether an FTP client is allowed to enter the SITE DEBUG command to change general tracing options.	Server	“DEBUGONSITE (FTP server) statement” on page 670
DEST	Specify the NJE destination to which the files are routed when you enter a PUT subcommand.	Server	“DEST (FTP server) statement” on page 671
DIRECTORY	Specify the number of directory blocks to be allocated for the directory of a PDS.	Both	“DIRECTORY (FTP client and server) statement” on page 671
DIRECTORYMODE	Specify how to treat the data set qualifiers below the current directory.	Both	“DIRECTORYMODE (FTP client and server) statement” on page 672
DSNTYPE	Specify the data set name type for new physical sequential data sets.	Both	“DSNTYPE (FTP client and server) statement” on page 673
DSWAITTIME	Specify the number of minutes that FTP tries to access an MVS data set that could not be obtained because another job or process was holding the data set.	Both	“DSWAITTIME (FTP client and server) statement” on page 674

Table 45. Summary of FTP client and server configuration statements (continued)

Statement	Description	Applies to client, server, or both	See
DSWAITTIMEREPLY	Specify how often to send the following reply message to the client while the FTP server is waiting for access to an MVS data set.	Server	“DSWAITTIMEREPLY (FTP server) statement” on page 675
DUMP	Specify to activate an extended trace dump ID.	Both	“DUMP (FTP client and server) statement” on page 677
DUMPONSITE	Specify whether an FTP client is allowed to enter the SITE DUMP command to change the extended tracing options.	Server	“DUMPONSITE (FTP server) statement” on page 678
EATTR	Specify whether new data sets can have extended attributes and whether the data sets can reside in the EAS.	Both	“EATTR (FTP client and server) statement” on page 678
EMAILADDRCHECK	Control the extent to which the FTP server validates e-mail addresses entered by FTP clients while logging in to the FTP server.	Server	“EMAILADDRCHECK (FTP server) statement” on page 679
ENCODING	Specify the type of data encoding on the network.	Both	“ENCODING (FTP client and server) statement” on page 680
EPSV4	Direct the FTP client to use EPSV and EPRT commands on IPv4 sessions.	Client	“EPSV4 (FTP client) statement” on page 681
EXTENSIONS	Enable FTP to recognize extensions to FTP that are not described in RFC 959.	Both	“EXTENSIONS (FTP client and server) statement” on page 682
FIFOIOTIME	Specify the FIFOIOTIME statement to set a timeout for reads and writes to a z/OS UNIX named pipe.	Both	“FIFOIOTIME (FTP client and server) statement” on page 684

Table 45. Summary of FTP client and server configuration statements (continued)

Statement	Description	Applies to client, server, or both	See
FIFOOPEN TIME	Specify the FIFOOPEN TIME statement to define the length of time that FTP waits after attempting to open a z/OS UNIX named pipe before reporting an error.	Both	“FIFOOPEN TIME (FTP client and server) statement” on page 685
FILETYPE	Specify the operational mode of FTP.	Both	“FILETYPE (FTP client and server) statement” on page 686
FTPKEEPALIVE	Specify the control connection keepalive timer value in seconds.	Both	“FTPKEEPALIVE (FTP client and server) statement” on page 687
FTPLOGGING	Specify whether the FTP server logs FTP session activity for unknown users (that is, users that are not anonymous users).	Server	“FTPLOGGING (FTP server) statement” on page 688
FWFRIENDLY	Specify how data connections are to be set up between the client and the server.	Client	“FWFRIENDLY (FTP client) statement” on page 689
HFSINFO	Specify a file containing welcome messages specific to each FTP server directory visited by an FTP client.	Server	“HFSINFO (FTP server) statement” on page 690
INACTIVE	Set the inactivity timer to a specified number of seconds.	Server	“INACTIVE (FTP Server) statement” on page 691
INACTTIME	Specify the amount of time to wait for an expected response from the server, on either the control or the data connection, before closing the session. Data transfer times that exceed this value does not cause session termination unless the time between data packet arrivals exceeds this value.	Client	“INACTTIME (FTP client) statement” on page 691

Table 45. Summary of FTP client and server configuration statements (continued)

Statement	Description	Applies to client, server, or both	See
ISPFSTATS	Allow FTP to create and maintain statistics for partitioned data set members.	Both	“ISPFSTATS (FTP client and server) statement” on page 692
JESENTRYLIMIT	Specify how many JES entries can be displayed at one time with the LIST or NLST command.	Server	“JESENTRYLIMIT (FTP server) statement” on page 693
JESGETBYDSN	Specify how to treat the foreign file name on a GET command when FILETYPE=JES is specified.	Server	“JESGETBYDSN (FTP server) statement” on page 693
JESINTERFACELEVEL	Specify the JES interface level.	Server	“JESINTERFACELEVEL (FTP server) statement” on page 694
JESLRECL	Specify the record length of the job being submitted.	Server	“JESLRECL (FTP server) statement” on page 696
JESPUTGETTO	Specify the number of seconds for the JES PutGet timeout.	Server	“JESPUTGETTO (FTP server) statement” on page 697
JESRECFM	Specify the record format of the job being submitted.	Server	“JESRECFM (FTP server) statement” on page 697
KEYRING	Define the key ring that contains the certificate to be used during the TLS handshake.	Client	“KEYRING (FTP client) statement” on page 698
LISTLEVEL	Specifies the format of the LIST command reply.	Server	“LISTLEVEL (FTP server) statement” on page 699
LISTSUBDIR	Specify whether subdirectories of the parent directory are listed when FTP generates a list of files.	Both	“LISTSUBDIR (FTP client and server) statement” on page 700
LOGCLIENTERR	Specify to activate client error logging feature.	Client	“LOGCLIENTERR (FTP client) statement” on page 702

Table 45. Summary of FTP client and server configuration statements (continued)

Statement	Description	Applies to client, server, or both	See
LOGINMSG	Specify the file containing messages to be displayed to FTP clients when they have successfully logged in.	Server	“LOGINMSG (FTP server) statement” on page 703
LRECL	Specify the size of the records in a data set.	Both	“LRECL (FTP client and server) statement” on page 704
MBDATACONN	Specify the multibyte data translation code pages for data connections.	Both	“MBDATACONN (FTP client and server) statement” on page 705
MBREQUIRELASTEOL	Specify whether FTP requires the last record of incoming multibyte files to end with the FTP standard EOL sequence.	Both	“MBREQUIRELASTEOL (FTP client and server) statement” on page 706
MBSSENDEOL	Specify to the FTP client or server what EOL sequence to use when the ENcoding value is MBCS.	Both	“MBSSENDEOL statement (FTP client and server) statement” on page 707
MGMTCLASS	Specify the SMS management class to be assigned to newly allocated data sets.	Both	“MGMTCLASS (FTP client and server) statement” on page 708
MIGRATEVOL	Specify the volume ID for migrated data sets not under the control of IBM Storage Management Systems.	Both	“MIGRATEVOL (FTP client and server) statement” on page 709
MVSINFO	Specify the MVS data sets whose contents are to be returned to the FTP client and displayed to the end user when a user changes directories.	Server	“MVSINFO (FTP server) statement” on page 710
MVSURLKEY	Specify a token that users can enter as part of an FTP URL to encode an MVS data set name.	Server	“MVSURLKEY (FTP server) statement” on page 710

Table 45. Summary of FTP client and server configuration statements (continued)

Statement	Description	Applies to client, server, or both	See
MYOPENTIME	Specify the amount of time to wait for a session to open before terminating the attempt and reporting an error.	Client	“MYOPENTIME (FTP client) statement” on page 711
NETRCLEVEL	Specify how the FTP client searches the NETRC data set for FTP server hostnames.	Client	“NETRCLEVEL (FTP client) statement” on page 712
NONSWAPD	Specify whether the FTP daemon is swappable.	Server	“NONSWAPD (FTP server) statement” on page 712
PASSIVEDATACONN	Specify to direct the server to verify the peer IP address of the data socket is the client's IP address.	Server	“PASSIVEDATACONN (FTP server) statement” on page 713
PASSIVEDATAPORTS	Specify a range of port numbers for the FTP server to use as listening data socket ports.	Server	“PASSIVEDATAPORTS (FTP server) statement” on page 714
PASSIVEIGNOREADDR	Specify to direct the FTP client to ignore the IP address returned from the server on the PASV reply on IPv4 sessions.	Client	“PASSIVEIGNOREADDR (FTP client) statement” on page 714
PASSIVEONLY	Controls whether data connections for the client are passive mode only.	Client	“PASSIVEONLY (FTP client) statement” on page 715
PDSTYPE	Specify the type of MVS directories (PDS or PDSE) FTP should allocate.	Both	“PDSTYPE (FTP client and server) statement” on page 717
PORTCOMMAND	Specify whether the PORT and EPRT commands are accepted or rejected.	Server	“PORTCOMMAND (FTP server) statement” on page 718

Table 45. Summary of FTP client and server configuration statements (continued)

Statement	Description	Applies to client, server, or both	See
PORTCOMMANDIPADDR	Specify the server to accept only PORT or EPRT commands whose IP address matches that of the client.	Server	“PORTCOMMANDIPADDR (FTP server) statement” on page 718
PORTCOMMANDPORT	Specify what range or port values the server accepts as a parameter for the PORT and EPRT commands.	Server	“PORTCOMMANDPORT (FTP server) statement” on page 719
PORTOFENTRY4	Specify the port of entry resource class to use for IPv4 login clients.	Server	“PORTOFENTRY4 (FTP server) statement” on page 720
PRIMARY	Specify the number of tracks, blocks, or cylinders for primary allocation.	Both	“PRIMARY (FTP client and server) statement” on page 720
PROGRESS	Specify the interval between progress report messages generated by the FTP client during an inbound or outbound file transfer.	Client	“PROGRESS (FTP client) statement” on page 721
QUOTESOVERRIDE	Specify use of single quotation marks in file name.	Both	“QUOTESOVERRIDE (FTP client and server) statement” on page 722
RDW	Specify whether RDWs are discarded upon retrieval.	Both	“RDW (FTP client and server) statement” on page 723
RECFM	Specify the record format of a data set.	Both	“RECFM (FTP client and server) statement” on page 723
REMOVEINBEOF	Remove UNIX EOF on inbound ASCII transfers.	Both	“REMOVEINBEOF (FTP client and server) statement” on page 725
REPLY226 (FTP server)	Direct the FTP server to reply to the FTP client with reply code 226 instead of reply code 250.	Server	“REPLY226 (FTP server) statement” on page 726
REPLYSECURITYLEVEL	Specify level of secure information returned in FTP replies.	Server	“REPLYSECURITYLEVEL (FTP server) statement” on page 727

Table 45. Summary of FTP client and server configuration statements (continued)

Statement	Description	Applies to client, server, or both	See
RESTGET	Specify whether the checkpoint data set is opened for a GET request.	Client	“RESTGET (FTP client) statement” on page 728
RESTPUT	Specify whether the server supports checkpoint and restart processing when receiving data (put operation).	Server	“RESTPUT (FTP server) statement” on page 728
RETPD	Specify the number of days a newly allocated data set should be retained.	Both	“RETPD (FTP client and server) statement” on page 729
SBDATACONN	Specify single-byte data translation for the data connection.	Both	“SBDATACONN (FTP client and server) statement” on page 731
SBSENDEOL	Specify to the FTP client or server what end of line (EOL) sequence to use for outbound ASCII file transfer when the ENcoding value is SBCS.	Both	“SBSENDEOL statement (FTP client and server) statement” on page 732
SBSUB	Specifies whether a substitution is allowed for a data byte that cannot be translated.	Both	“SBSUB (FTP client and server) statement” on page 733
SBSUBCHAR	Specifies the single-byte substitution character for untranslatable data characters.	Both	“SBSUBCHAR (FTP client and server) statement” on page 734
SBTRANS	Specify the SBCS translation table to be used for the data connection.	Client	“SBTRANS (FTP client) statement” on page 735
SECONDARY	Specify the number of tracks, blocks, or cylinders for secondary allocation.	Both	“SECONDARY (FTP client and server) statement” on page 735

Table 45. Summary of FTP client and server configuration statements (continued)

Statement	Description	Applies to client, server, or both	See
SECURE_CTRLCONN	Specify the SECURE_CTRLCONN statement to specify the minimum level of security allowed for the control connection.	Both	“SECURE_CTRLCONN (FTP client and server) statement” on page 736
SECURE_DATACONN	Specify the SECURE_DATACONN statement to specify the minimum level of security required on the data connection.	Both	“SECURE_DATACONN (FTP client and server) statement” on page 738
SECURE_FTP	Specify the SECURE_FTP statement to specify whether authentication is required.	Both	“SECURE_FTP (FTP client and server) statement” on page 739
SECURE_HOSTNAME	Specify the SECURE_HOSTNAME statement to specify whether the client verifies the host name in the server's certificate.	Client	“SECURE_HOSTNAME (FTP client) statement” on page 741
SECUREIMPLICITZOS	Specify when the security of the session should be negotiated for implicit TLS connections.	Both	“SECUREIMPLICITZOS (FTP client and server) statement” on page 741
SECURE_LOGIN	Specify the SECURE_LOGIN statement to set the authorization level required for users.	Server	“SECURE_LOGIN (FTP server) statement” on page 743
SECURE_MECHANISM	Specifies which security mechanism the client uses.	Client	“SECURE_MECHANISM (FTP client) statement” on page 744
SECURE_PASSWORD	Specify whether a password is required by the FTP server for an TLS protected session.	Server	“SECURE_PASSWORD (FTP server) statement” on page 745
SECURE_PASSWORD_KERBEROS	Specify whether a password is required for a Kerberos protected session.	Server	“SECURE_PASSWORD_KERBEROS (FTP server) statement” on page 746

Table 45. Summary of FTP client and server configuration statements (continued)

Statement	Description	Applies to client, server, or both	See
SECURE_PBSZ	Specify the maximum size of the encoded data blocks sent during file transfer.	Both	“SECURE_PBSZ (FTP client and server) statement” on page 748
SECURE_SESSION_REUSE	Specify whether session reuse is required when SSL/TLS is used to protect the connections.	Both	“SECURE_SESSION_REUSE (FTP client and server) statement” on page 749
SEQNUMSUPPORT	Specify that sequence numbers in files designated by the ddname INPUT are ignored.	Client	“SEQNUMSUPPORT (FTP client) statement” on page 751
SMF	Specify the default SMF record subtype for all SMF records.	Server	“SMF (FTP server) statement” on page 752
SMFAPPE	Specify the SMF record subtype for the APPEND subcommand.	Server	“SMFAPPE (FTP server) statement” on page 754
SMFDCFG	Specify a type 119 SMF record of subtype 71 is collected for the FTP daemon configuration information when the FTP daemon starts.	Server	“SMFDCFG (FTP server) statement” on page 755
SMFDEL	Specify the SMF record subtype for the DELETE subcommand.	Server	“SMFDEL (FTP server) statement” on page 756
SMFEXIT	Call the FTPSMFEX user exit routine.	Server	“SMFEXIT (FTP server) statement” on page 757
SMFJES	Collect SMF records when FILETYPE is JES.	Server	“SMFJES (FTP server) statement” on page 758
SMFLOGN	Specify the SMF record subtype when recording logon failures.	Server	“SMFLOGN (FTP server) statement” on page 759
SMFREN	Specify the SMF record subtype for the RENAME subcommand.	Server	“SMFREN (FTP server) statement” on page 760
SMFRETR	Specify the SMF record subtype for the RETR subcommand.	Server	“SMFRETR (FTP server) statement” on page 761

Table 45. Summary of FTP client and server configuration statements (continued)

Statement	Description	Applies to client, server, or both	See
SMFSQL	Collect SMF records when FILETYPE is SQL.	Server	“SMFSQL (FTP server) statement” on page 762
SMFSTOR	Specify the SMF record subtype for the STOR and STOU subcommands.	Server	“SMFSTOR (FTP server) statement” on page 763
SOCKSCONFIGFILE	Specify the SOCKS server configuration file the FTP client uses to determine which FTP servers require SOCKS protocols.	Client	“SOCKSCONFIGFILE (FTP client) statement” on page 764
SPACETYPE	Specify whether newly allocated data sets are allocated in blocks, cylinders, or tracks.	Both	“SPACETYPE (FTP client and server) statement” on page 765
SPREAD	Specify output in spreadsheet format when file type is SQL.	Both	“SPREAD (FTP client and server) statement” on page 766
SQLCOL	Specify the column headings of the output file.	Both	“SQLCOL (FTP client and server) statement” on page 767
SSLV3	Control whether SSLV3 is enabled for connections that are secured by using TLS implemented by FTP.	Client	“SSLV3 (FTP client connection) statement” on page 768
STARTDIRECTORY	Specify which file system is used initially when a new user logs in.	Server	“STARTDIRECTORY (FTP server) statement” on page 768
STORCLASS	Specify the SMS-managed storage class for the FTP server.	Both	“STORCLASS (FTP client and server) statement” on page 769
SUPPRESSIGNOREWARNINGS	Instruct FTP not to issue message EZYFT47I whenever it ignores a statement coded in FTP.DATA	Both	“SUPPRESSIGNOREWARNINGS (FTP client and server) statement” on page 770
TAPERADSTREAM	Specify whether to use a more efficient read path (read as stream) to retrieve tape data sets from the server.	Server	“TAPERADSTREAM (FTP server) statement” on page 771

Table 45. Summary of FTP client and server configuration statements (continued)

Statement	Description	Applies to client, server, or both	See
TLSMECHANISM	Specify how TLS security is implemented.	Both	“TLSMECHANISM (FTP client and server) statement” on page 772
TLSPORT	Set the secure port on which the FTP client or the FTP server implicitly protects the FTP session with TLS.	Both	“TLSPORT (FTP client and server) statement” on page 773
TLSRFCLEVEL	Specify the level of RFC 4217 (<i>Securing FTP with TLS</i>) that FTP supports.	Both	“TLSRFCLEVEL (FTP client and server) statement” on page 774
TLSTIMEOUT	Specify the maximum time between full TLS handshakes.	Client	“TLSTIMEOUT (FTP client) statement” on page 775
TLSV1	Control whether TLSv1 is enabled for connections that are secured by using TLS implemented by FTP.	Client	“TLSV1 (FTP client) statement” on page 776
TRACE	Start tracing.	Both	“TRACE (FTP client and server) statement” on page 776
TRACEAPI	Define a control for tracing for a user-written program that uses the callable API interface for the z/OS FTP client.	Client	“TRACEAPI (FTP client) statement” on page 777
TRAILINGBLANKS	Include trailing blanks in fixed format data sets when retrieved.	Both	“TRAILINGBLANKS (FTP client and server) statement” on page 778
TRUNCATE	Allow truncating records that are longer than LRECL.	Both	“TRUNCATE (FTP client and server) statement” on page 778
UCOUNT	Specify the unit count for new data set allocations.	Both	“UCOUNT (FTP client and server) statement” on page 779
UCSHOSTCS	Specify the EBCDIC code set to be used for data conversion to or from Unicode.	Both	“UCSHOSTCS (FTP client and server) statement” on page 780

Table 45. Summary of FTP client and server configuration statements (continued)

Statement	Description	Applies to client, server, or both	See
UCSSUB	Specify whether Unicode-to-EBCDIC conversion should use the EBCDIC substitution character or cause the data transfer to be terminated if a Unicode character cannot be converted to a character in the target EBCDIC code set.	Both	“UCSSUB (FTP client and server) statement” on page 780
UCSTRUNC	Specify whether the transfer of Unicode data should be aborted if truncation occurs at the MVS host.	Both	“UCSTRUNC (FTP client and server) statement” on page 781
UMASK	Specify the file mode creation mask.	Both	“UMASK (FTP client and server) statement” on page 781
UNICODEFILESYSTEMBOM	Specify whether to add a Byte Order Mark (BOM) to a file stored in the local file system when the file system code page is UNICODE.	Both	“UNICODEFILESYSTEMBOM (FTP client and server) statement” on page 782
UNITNAME	Specify the unit type for allocation of new data sets.	Both	“UNITNAME (FTP client and server) statement” on page 784
UNIXFILETYPE	Specify the UNIXFILETYPE statement in the FTP server and client to indicate whether to treat z/OS UNIX file system files as regular files or as z/OS UNIX named pipes during file transfer.	Both	“UNIXFILETYPE (FTP client and server) statement” on page 784
VCOUNT	Specify the volume count for allocation of new data sets.	Both	“VCOUNT (FTP client and server) statement” on page 786

Table 45. Summary of FTP client and server configuration statements (continued)

Statement	Description	Applies to client, server, or both	See
VERIFYUSER	Specify whether the FTP server should verify whether a user attempting to log into FTP has been granted access to the server's port profile in the SERVAUTH class.	Server	“VERIFYUSER (FTP server) statement” on page 787
VOLUME	Specify the volume serial number or numbers for allocation of new data sets.	Both	“VOLUME (FTP client and server) statement” on page 788
WRAPRECORD	Specify whether data is wrapped or truncated if no new-line character is encountered before the logical record length is reached.	Both	“WRAPRECORD (FTP client and server) statement” on page 789
WRTAPEFASTIO	Allow write to tape of ASCII stream data to use BSAM I/O routines.	Both	“WRTAPEFASTIO (FTP client and server) statement” on page 790
XLATE	Specify the translation table data set for the data connection.	Server	“XLATE (FTP server) statement” on page 791

FTP.DATA data set statements

These topics cover, in detail, the statements you can use in the FTP.DATA data set. Each statement heading identifies whether the statement applies to FTP client, server, or both.

ACCESSERRORMSGS (FTP server) statement

Use the ACCESSERRORMSGS statement to allow FTP server to send detailed login failure replies to an FTP client.

Syntax

Parameters

FALSE

Do not send detailed login failure replies to an FTP client.

TRUE

Send detailed login failure replies to an FTP client.

Examples

To send detailed login failure replies to an FTP client, use the following code:

```
ACCESSERRORMSGs TRUE
```

Usage notes

The text of detailed login failure replies can be traced using the ACC parameter of the DEBUG statement. You do not need to code ACCESSERRORMSGs TRUE to trace this information.

Related topics

- [“DEBUG \(FTP client and server\) statement” on page 668](#)

ADMINEMAILADDRESS (FTP server) statement

Use the ADMINEMAILADDRESS statement to specify a value to substitute for the %E keyword used for the data set or file specified in the BANNER, LOGINMSG, ANONYMOUSMVSINFO, ANONYMOUSLOGINMSG, HFSINFO, and MVSINFO statements. This statement is used to specify the e-mail address of the FTP server administrator.

Syntax

➤ ADMINEMAILADDRESS — *value* ➤

Parameters

value

The e-mail address displayed when %E is used in BANNER, LOGINMSG, ANONYMOUSMVSINFO, ANONYMOUSLOGINMSG, HFSINFO, and MVSINFO displays.

Examples

```
ADMINEMAILADDRESS TheWebMaster@Myhost.MyCompany.Com
```

- [“MVSINFO \(FTP server\) statement” on page 710](#)

ANONYMOUS (FTP server) statement

Use the ANONYMOUS statement to allow remote users to log in as anonymous users.

You can use ANONYMOUSLEVEL, ANONYMOUSFILEACCESS, ANONYMOUSFILETYPESQL, ANONYMOUSFILETYPEJES, and ANONYMOUSFILETYPESEQ in conjunction with ANONYMOUSLEVEL 3 to restrict anonymous users' access to data sets and files. Use ANONYMOUSMVSINFO, ANONYMOUSLOGINMSG, ANONYMOUSHFSINFO, and EMAILADDRCHECK to customize the FTP session for anonymous users.

Requirement: If you choose an ANONYMOUSLEVEL value greater than 1, and you choose STARTDIRECTORY HFS, you must create an anonymous directory structure in the z/OS UNIX. For more information about [anonymous logins](#), see [z/OS Communications Server: IP Configuration Guide](#).

Syntax

Parameters

user_id

The security access facility (SAF) identity of the anonymous user. When a remote user enters ANONYMOUS as a user ID, the FTP server treats the login request as though the specified *user_id* was entered instead of ANONYMOUS. The user is prompted for the password to *user_id*. If the user enters the correct password or password phrase, the user is logged in as the specified *user_id*.

If you are using RACF, the system builds a user accessor environment element (ACEE), and the ANONYMOUS user has access to any resources available to the specified user ID.

user_id/password

The security access facility (SAF) identity and password the FTP server uses for anonymous user. When a remote user enters ANONYMOUS as the user ID, the FTP server treats the login request as though the specified *user_id* was entered instead of ANONYMOUS. The FTP server automatically provides the *password* for the specified *user_id* and the user is logged in as the specified *user_id*. If you are using RACF, the system builds the user ACEE for the specified *user_id* and the ANONYMOUS user has authorized access to the same resources as the specified *user_id*.

If ANONYMOUSLEVEL 3 is specified, the behavior is different. See [“ANONYMOUSLEVEL \(FTP server\) statement”](#) on page 638 for details.

Restriction: Do not code a password phrase as *password*.

user_id/SURROGATE

Allows a remote user to enter ANONYMOUS as a user ID. When ANONYMOUS is entered as the user ID, the FTP server treats the login request as though the specified *user_ID* was entered instead of ANONYMOUS. The FTP Server calls RACF and checks if this *user_ID* is allowed to login without a password or password phrase.

Requirement: In order to use this option, ANONYMOUSLEVEL must be greater or equal to 3. See [“ANONYMOUSLEVEL \(FTP server\) statement”](#) on page 638 for details.

Examples

Allow a remote user to enter ANONYMOUS as a user ID and be connected to the server system with the user ID of TERMABC:

Tip:

- If you code ANONYMOUSLEVEL 3 in FTP.DATA, you can code additional statements to configure ANONYMOUS support and security. See **Related topics** for more information.

Requirements:

- If you specify a user ID on the ANONYMOUS statement, that user ID must be defined and have a z/OS UNIX segment defined or set to the default value.
- If you code the ANONYMOUS statement without a user ID, the user ID ANONYMO must be defined and must have a z/OS UNIX segment defined or set to the default value.

Results:

- If you code the ANONYMOUS statement without a user ID:
 - The end user is not prompted for a password.
 - If you are using the FTCHKPWD user exit,
 - the exit is called with user ID ANONYMO and password *.
 - If ANONYMOUSLEVEL 3 is coded in FTP.DATA and the FTP server prompts the FTP client for an email address, the email address is passed to the exit as the userdata parameter.
 - The user ID ANONYMO and the STARTDIRECTORY statement in FTP.DATA determine the initial working directory. See [initial working directory consideration in the z/OS Communications Server: IP User's Guide and Commands](#) for more information.
 - The initial working directory is ANONYMO when the STARTDIRECTORY MVS statement is coded in FTP.DATA.
 - The initial working directory is the home directory for the ANONYMO user ID when the STARTDIRECTORY HFS statement is coded in FTP.DATA.
 - If you are using RACF, a user who logs in as 'anonymous' has access to any resources accessible to the ANONYMO user ID.
- If you code the ANONYMOUS statement with a user ID, the user ID you coded and the STARTDIRECTORY statement determine the initial working directory. See [initial working directory consideration in the z/OS Communications Server: IP User's Guide and Commands](#) for more information.
- There is no default for ANONYMOUS. If you do not code the ANONYMOUS statement in FTP.DATA, users are not allowed to log in anonymously.
- See [z/OS Communications Server: IP Configuration Guide](#) for more information about [anonymous logins](#).
- When ANONYMOUS is enabled, it is recommended that ANONYMOUSLEVEL be set to 3 and ANONYMOUSFILETYPEJES be set to FALSE. Otherwise, anonymous users can submit jobs to the system. You can use IBM Health Checker CSAPP_FTPD_ANONYMOUS_JES to detect whether anonymous users can submit jobs to the system. For more details about IBM Health Checker, see [z/OS Communications Server: IP Diagnosis Guide](#).

- [“EMAILADDRCHECK \(FTP server\) statement” on page 679](#)
- [“STARTDIRECTORY \(FTP server\) statement” on page 768](#)
- [“The FTCHKPWD user exit” on page 596](#)

ANONYMOUSFILEACCESS (FTP server) statement

Use ANONYMOUSFILEACCESS to set the type of files (MVS, z/OS UNIX, or both) that anonymous users are allowed to access. If STARTDIRECTORY is HFS and ANONYMOUSFILEACCESS is HFS, the anonymous user is not allowed to access MVS data sets. If STARTDIRECTORY is MVS and ANONYMOUSFILEACCESS is MVS, the anonymous user is not allowed to access z/OS UNIX files. If STARTDIRECTORY and ANONYMOUSFILEACCESS contradict each other, the anonymous user is not allowed to log in (the login fails). A value of BOTH allows the anonymous user to switch back and forth between MVS and z/OS UNIX data sets.

Restriction: ANONYMOUSFILEACCESS is valid only when ANONYMOUSLEVEL 3 or greater is specified.

Syntax

Parameters

BOTH

Allows anonymous users to access both z/OS UNIX and MVS.

MVS

Allows anonymous users access to only MVS data sets.

HFS

Allows anonymous users access to only z/OS UNIX data sets. This is the default.

Examples

Allow the anonymous users to access both MVS and z/OS UNIX files:

```
ANONYMOUSFILEACCESS BOTH
```

Usage notes

ANONYMOUSFILEACCESS is valid only when ANONYMOUSLEVEL 3 is specified.

- [“STARTDIRECTORY \(FTP server\) statement” on page 768](#)

ANONYMOUSFILETYPEJES (FTP server) statement

Use the ANONYMOUSFILETYPEJES statement to control the access of anonymous users to the FTP server running in JES operation mode (FILETYPE=JES).

Restriction: The ANONYMOUSFILETYPEJES statement is recognized only when ANONYMOUSLEVEL 3 or greater is specified.

Syntax

Parameters

TRUE

Anonymous users can log in to an FTP server running with the FILETYPE=JES setting, and anonymous users can issue the SITE FILETYPE=JES command.

FALSE

Anonymous users cannot log in to an FTP server running with the FILETYPE=JES setting, and anonymous users cannot issue the SITE FILETYPE=JES command.

Examples

Set the anonymous environment to allow anonymous clients to enter SITE FILETYPE=JES:

```
ANONYMOUSFILETYPEJES TRUE
```

Usage notes

If you specify the FILETYPE statement, its setting must be consistent with the ANONYMOUSFILETYPEJES setting or anonymous users are not able to log in to FTP.

When ANONYMOUS is enabled, it is recommended that ANONYMOUSLEVEL be set to 3 and ANONYMOUSFILETYPEJES be set to FALSE. Otherwise, anonymous users can submit jobs to the system. You can use IBM Health Checker CSAPP_FTPD_ANONYMOUS_JES to detect whether anonymous users can submit jobs to the system. For more details about IBM Health Checker, see [z/OS Communications Server: IP Diagnosis Guide](#).

- [“FILETYPE \(FTP client and server\) statement” on page 686](#)
- [“JESGETBYDSN \(FTP server\) statement” on page 693](#)

ANONYMOUSFILETYPESEQ (FTP server) statement

Use the ANONYMOUSFILETYPESEQ statement to control the access of anonymous users to the FTP server running in normal mode (FILETYPE=SEQ). This statement is recognized only when ANONYMOUSLEVEL 3 or greater is specified.

Syntax

Parameters

TRUE

Anonymous users can log into an FTP server running with the FILETYPE=SEQ setting, and anonymous users can issue the SITE FILETYPE=SEQ command.

FALSE

Anonymous users cannot log into an FTP server running with the FILETYPE=SEQ setting, and anonymous users cannot issue the SITE FILETYPE=SEQ command.

Examples

Set the anonymous environment to allow anonymous users to enter SITE FILETYPE=SEQ:

```
ANONYMOUSFILETYPESEQ TRUE
```

Usage notes

Most FTP servers allow anonymous users to use filetype SEQ.

If you specify the FILETYPE statement in FTP.DATA, its setting must be consistent with ANONYMOUSFILETYPESEQ or anonymous users are not able to log in to FTP.

Related topics

- [“ANONYMOUSFILETYPEJES \(FTP server\) statement” on page 633](#)
- [“ANONYMOUSFILETYPESQL \(FTP server\) statement” on page 634](#)
- [“ANONYMOUSLEVEL \(FTP server\) statement” on page 638](#)
- [“FILETYPE \(FTP client and server\) statement” on page 686](#)

ANONYMOUSFILETYPESQL (FTP server) statement

Use the ANONYMOUSFILETYPESQL statement to control the access of anonymous users to the FTP server running in SQL mode (FILETYPE=SQL).

Restriction: This statement is recognized only when ANONYMOUSLEVEL 3 or greater is specified.

Syntax

Parameters

TRUE

Anonymous users can log into an FTP server running with the FILETYPE=SQL setting, and anonymous users can issue the SITE FILETYPE=SQL command.

FALSE

Anonymous users cannot log into an FTP server running with the FILETYPE=SQL setting, and anonymous users cannot issue the SITE FILETYPE=SQL command.

Examples

Set the anonymous environment to allow anonymous users to enter SITE FILETYPE=SQL:

```
ANONYMOUSFILETYPESQL TRUE
```

Usage notes

If you specify the FILETYPE statement, its setting must be consistent with the ANONYMOUSFILETYPESQL setting or anonymous users are not able to log in to FTP.

Related topics

- [“ANONYMOUSFILETYPEJES \(FTP server\) statement” on page 633](#)
- [“ANONYMOUSFILETYPESEQ \(FTP server\) statement” on page 633](#)
- [“ANONYMOUSLEVEL \(FTP server\) statement” on page 638](#)
- [“FILETYPE \(FTP client and server\) statement” on page 686](#)

ANONYMOUSFTPLOGGING (FTP server) statement

Use the ANONYMOUSFTPLOGGING statement to indicate whether the FTP server should log FTP server activity for an anonymous user. The following types of activities are logged:

- Connectivity
- Authentication
- Access
- Allocation
- Deallocation
- Data transfer
- JES job submission
- SQL query
- Abnormal end

The activities are logged in the SYSLOGD file. Each logging entry has a message number.

Syntax

Parameters

TRUE

The FTP server should log FTP session activity.

When ANONYMOUSFTPLOGGING is TRUE, a long delay in login processing might occur because the FTP server issues a DNS query to resolve the remote host IP address.

FALSE

The FTP server should not log FTP session activity.

Examples

To request that the FTP server log session activity for an anonymous user:

```
ANONYMOUSFTPLOGGING TRUE
```

Usage notes

- Each activity logging message has a message number within the range of EZYFS50 to EZYFS95.
- ANONYMOUSFTPLOGGING controls logging for anonymous users.
- If ANONYMOUSFTPLOGGING is TRUE, connectivity, authentication, and access activity log entries are made for all sessions because the server does not know whether the login is anonymous or not.

Related topics

See [“FTPLOGGING \(FTP server\) statement”](#) on page 688 to control logging for a non-anonymous user.

ANONYMOUSHFSDIRMODE (FTP server) statement

Use the ANONYMOUSHFSDIRMODE statement to specify the mode bits used for directories created by anonymous users.

Restriction: This statement is recognized only when ANONYMOUSLEVEL 3 or greater is specified.

Syntax

Parameters

nnn

The three octal digits that describe the mode bits. It is passed directly to chmod() function to set the mode bits for directories created by anonymous users.

Examples

To prevent anyone from listing new directories created by anonymous users, use the following example.

```
ANONYMOUSHFSDIRMODE 333
```

Usage notes

- This statement is recognized only when ANONYMOUSFILEACCESS HFS or ANONYMOUSFILEACCESS BOTH is specified.

Related topics

- [“ANONYMOUSFILEACCESS \(FTP server\) statement” on page 632](#)
- [“ANONYMOUSHFSFILEMODE \(FTP server\) statement” on page 637](#)
- [“ANONYMOUSLEVEL \(FTP server\) statement” on page 638](#)

ANONYMOUSHFSFILEMODE (FTP server) statement

Use the ANONYMOUSHFSFILEMODE statement to specify the mode bits used when storing files created by anonymous users.

Restriction: This statement is recognized only when ANONYMOUSLEVEL 3 or greater is specified. This statement has no meaning if ANONYMOUSLEVEL 3 is not specified.

Syntax

Parameters

nnn

The three octal digits describing the mode bits. It is passed directly to the `chmod()` function to set the mode bits for files created by anonymous users.

Examples

To prevent anyone from accessing files written by anonymous users, use the following example.

```
ANONYMOUSHFSFILEMODE 000
```

Usage notes

- This statement is recognized only when ANONYMOUSFILEACCESS HFS or ANONYMOUSFILEACCESS BOTH is specified.

Related topics

- [“ANONYMOUSFILEACCESS \(FTP server\) statement” on page 632](#)
- [“ANONYMOUSHFSDIRMODE \(FTP server\) statement” on page 636](#)
- [“ANONYMOUSLEVEL \(FTP server\) statement” on page 638](#)

ANONYMOUSHFSINFO (FTP server) statement

Use the ANONYMOUSHFSINFO statement to specify a file containing information messages specific to each FTP server directory during an FTP login session.

Restriction: This statement affects only FTP clients logged in as anonymous users.

Syntax

➤ ANONYMOUSHFSINFO — *file-mask* ➤

Parameters

file-mask

The file-mask is an z/OS UNIX file mask used to find a z/OS UNIX information file for anonymous users. The file mask can contain wildcards or it can be a full file name (for example, `readme*`). When a user changes directories, a search is made with the specified mask. The contents of the first file found is returned to the FTP client and is displayed to the end user. If no file matches the specified mask, no information is displayed to the end user. If multiple files satisfy a generic file-mask, the first is chosen.

Restriction: The generic file name only works when an asterisk (*) is at the end of a character string.

Examples

Use the following example to display the contents of the first file matching `readme*` in any z/OS UNIX directory to which an anonymous user changes. If the directory has no files matching `readme*`, no messages are displayed.

```
ANONYMOUSHFSINFO readme*  
; Anonymous HFS info file-mask  
; login
```

Usage notes

- If an anonymous user changes to a directory containing no files matching the file-mask, no information is displayed to the anonymous user.

- [“MVSINFO \(FTP server\) statement” on page 710](#)

ANONYMOUSLEVEL (FTP server) statement

Use the ANONYMOUSLEVEL statement to set the type of access permitted to users who log in as anonymous users.

Syntax

Parameters

1

Anonymous logins are as documented in the ANONYMOUS statement. Anonymous users are not affected by the keywords and function of the following:

- ANONYMOUSFILETYPESEQ

- ANONYMOUSFILETYPEJES
- ANONYMOUSFILETYPESQL
- ANONYMOUSFILEACCESS
- ANONYMOUSHFSFILEMODE
- ANONYMOUSHFSDIRMODE
- EMAILADDRCHECK

2

Anonymous logins are allowed as documented in “ANONYMOUS (FTP server) statement” on page 630, except that the anonymous user's root directory is set with the UNIX call `chroot()` to the anonymous userid home directory. This confines the anonymous user's z/OS UNIX access to the anonymous userID home directory and its subdirectories. A umask of 777 is used for all files and directories created by anonymous users.

3

Anonymous logins are allowed as is documented in the ANONYMOUS statement, but more control is given to customize access. This is the default.

The FTP.DATA statements used to give this control are:

- ANONYMOUSFILETYPESEQ
- ANONYMOUSFILETYPEJES
- ANONYMOUSFILETYPESQL
- ANONYMOUSFILEACCESS
- ANONYMOUSHFSFILEMODE
- ANONYMOUSHFSDIRMODE
- EMAILADDRCHECK

The UNIX call `chroot()` is used to set the anonymous user's root directory to that user's home directory.

Instead of establishing a fixed UMASK for files and directories created by the anonymous user, the permission bits for files and directories are as defined by the ANONYMOUSHFSFILEMODE and ANONYMOUSHFSDIRMODE statements.

FTP clients are not allowed to issue the USER command to enter or leave anonymous login mode.

The password prompting behavior for anonymous users is different than for ANONYMOUSLEVEL 1 and 2. When the ANONYMOUS statement is coded with no user ID or password, the FTP server prompts the user to enter an e-mail address as a password. When the ANONYMOUS statement is coded with a user ID, the FTP server prompts the user to enter a password, as documented in “ANONYMOUS (FTP server) statement” on page 630. When the ANONYMOUS statement is coded with a user ID and password, the user is prompted to enter an e-mail address as a password. Control the degree of e-mail address validation with the EMAILADDRCHECK password.

When customizing FTP server to support ANONYMOUS logins, FTP server supports a way to avoid placing a plain-text password in the ANONYMOUS statement by supporting a special parameter, SURROGATE. This is shown in the following example:

```
ANONYMOUS userid/SURROGATE
```

For more information about anonymous logins, see [z/OS Communications Server: IP Configuration Guide](#) or “ANONYMOUS (FTP server) statement” on page 630.

Requirement: In order to support this function, the FTP user ID must be defined to process users without passwords.

Examples

Set the anonymous environment to use controls for accessing different resources:

Usage notes

- For ANONYMOUSLEVEL 2 and greater, when STARTDIRECTORY is z/OS UNIX, you must create a specific directory structure and contents within the anonymous user's home directory. This directory structure is needed so the FTP client maintains addressability to needed executable applications after the chroot() is executed. See [z/OS Communications Server: IP Configuration Guide](#) for details about creating the required [anonymous logins](#).
- If you specify ANONYMOUSLEVEL 3 and either ANONYMOUS with no parameters or ANONYMOUS with both user ID and password, the user is prompted for an e-mail address to log in to FTP. The EMAILADDRCHECK keyword controls the extent to which the e-mail address entered is validated. See [“EMAILADDRCHECK \(FTP server\) statement”](#) on page 679 for more information.
- When ANONYMOUS is enabled, it is recommended that ANONYMOUSLEVEL be set to 3 and ANONYMOUSFILETYPEJES be set to FALSE. Otherwise, anonymous users can submit jobs to the system. You can use IBM Health Checker CSAPP_FTPD_ANONYMOUS_JES to detect whether anonymous users can submit jobs to the system. For more details about IBM Health Checker, see [z/OS Communications Server: IP Diagnosis Guide](#).

- [“STARTDIRECTORY \(FTP server\) statement”](#) on page 768

ANONYMOUSLOGINMSG (FTP server) statement

Use the ANONYMOUSLOGINMSG statement to specify a z/OS UNIX file or MVS data set whose contents are to be displayed to the end user when an anonymous user logs in.

Syntax

➤ ANONYMOUSLOGINMSG — *file-path* ➤

Parameters

file-path

Either a z/OS UNIX path name or a fully qualified MVS data set name. If the first character is a slash, *file-path* is considered a z/OS UNIX name; otherwise, it is treated as a fully qualified MVS data set name.

Rules:

- When specifying a z/OS UNIX file-path, *file-path* is always an absolute pathname in the anonymous user's root directory. The anonymous user's root directory depends on the values coded or set to the default value for ANONYMOUSLEVEL and STARTDIRECTORY statements in FTP.DATA.

- When ANONYMOUSLEVEL 1 is coded in FTP.DATA, or when STARTDIRECTORY MVS is coded in FTP.DATA, the anonymous user's root directory is the z/OS UNIX root directory. Therefore, you specify *file-path* as an absolute pathname in the z/OS UNIX without regard to the anonymous user's home directory.
- When the ANONYMOUSLEVEL value is greater than one, and the STARTDIRECTORY is z/OS UNIX, the anonymous user's root directory is the anonymous userID home directory. Therefore, the file identified by *file-path* has to reside within the anonymous user's home directory or one of its subdirectories, and you specify *file-path* as an absolute pathname, but relative to the anonymous userID home directory.

Examples

To display the contents of the TCPIP.ANONYM.LOGIN.MSG data set when an anonymous user logs into FTP, enter the following code:

```
ANONYMOUSLOGINMSG TCPIP.ANONYM.LOGIN.MSG
```

For example, you might have created userID GUEST with home directory /u/anonymous for anonymous logins, and you have coded these statements in FTP.DATA:

- ANONYMOUS GUEST
- ANONYMOUSLEVEL 3
- STARTDIRECTORY HFS
- ANONYMOUSFILEACCESS HFS

To display the contents of /u/anonymous/banner when an anonymous user logs into FTP, code the following statement in FTP.DATA:

```
ANONYMOUSLOGINMSG /banner
```

To display the contents of /etc/banner when an anonymous user logs into FTP, you must copy /etc/banner into /u/anonymous or into a subdirectory such as /u/anonymous/etc because the z/OS UNIX directory /etc is outside the anonymous userID's root directory.

Again, suppose you have created userID GUEST with home directory /u/anonymous for anonymous logins, and you have coded these statements in FTP.DATA:

- ANONYMOUS GUEST
- ANONYMOUSLEVEL 1

To display the contents of /u/anonymous/banner when an anonymous user logs into FTP, code the following statement in FTP.DATA:

```
ANONYMOUSLOGINMSG /u/anonymous/banner
```

In this case you specify the pathname /u/anonymous/banner because the anonymous userID root directory is /.

Usage notes

- ANONYMOUSLOGINMSG is not dependent upon the value of ANONYMOUSLEVEL.
- If an installation is required to display the same login messages to both anonymous and known users, the same file-path can be specified on both the ANONYMOUSLOGINMSG and LOGINMSG statements.

ANONYMOUSMVSINFO (FTP server) statement

Use the ANONYMOUSMVSINFO statement to specify the MVS data sets whose contents should be displayed when an anonymous user changes directory. The statement identifies a low-level qualifier (LLQ) to be appended to the current path whenever an anonymous FTP user changes directories to an MVS data set.

Syntax

➤ ANONYMOUSMVSINFO — MVS-LLQ ➤

Parameters

MVS-LLQ

The MVS-LLQ is the MVS low-level qualifier (LLQ) to be appended to the current MVS path whenever an anonymous FTP user changes directories to an MVS data set. If a data set matches the current path appended LLQ, the contents of the data set are to be returned to the FTP user and displayed to the end user (when the end user is an anonymous user).

Examples

To display a readme file the first time an anonymous user changes directory to high-level qualifiers, use the statement in the following example. In this example, an MVS high-level qualifier of *productname* might have a readme file for each product, and when an anonymous user changes directory to the product, the readme file would be displayed.

```
ANONYMOUSMVSINFO README
```

Usage notes

- You can use MVSINFO to specify the same LLQ and ANONYMOUSMVSINFO. In this way, anonymous and known users can display the same information.
- The ANONYMOUSMVSINFO data set is displayed only the first time a user changes to a specific directory. The FTP server maintains a finite history of CD commands entered by the FTP user. If the FTP user performs frequent CD commands, it is possible the user sees the same ANONYMOUSMVSINFO file more than once.
- ANONYMOUSMVSINFO applies only to anonymous users. For all other users, a banner informational message can be displayed using the MVSINFO statement.

Related topics

- “HFSINFO (FTP server) statement” on page 690
- “MVSINFO (FTP server) statement” on page 710

APPLNAME (FTP server) statement

Use the APPLNAME statement to specify the FTP server application name (applname).

Syntax

➤ APPLNAME — *applname* ➤

Parameters

applname

The FTP server application name.

Examples

Use OMVSAPPL as the FTP server application name:

```
APPLNAME OMVSAPPL
```

Usage notes

If you do not specify any value for APPLNAME, FTP server uses job name as the application name. The maximum length of this statement is 8 bytes. Any invalid value is ignored.

ASATRANS (FTP client and server) statement

Use the ASATRANS statement to control the way ASA file transfers are managed. Choose either to have the control characters converted by the C runtime library during a file transfer or transferred without conversion.

The complete conversion process is described in the [z/OS XL C/C++ Programming Guide](#).

Server

This setting applies when transferring files from the server's system (for example, with a GET subcommand).

Client

This setting applies when transferring files from the client's system (for example, with a PUT subcommand).

Syntax

Parameters

TRUE

Characters in column 1 of the file being transferred are converted to C control character sequences.

FALSE

Characters in column 1 of the file being transferred are not converted. This is the default.

Examples

Convert characters in column 1 of the file being transferred:

```
ASATRANS TRUE
```

AUTOMOUNT (FTP client and server) statement

Use the AUTOMOUNT statement to permit unmounted DASD volumes to be mounted automatically.

Server

This setting applies when accessing files on the server's system.

Client

This setting applies when accessing files on the client's system.

Syntax

Parameters

TRUE

Permits unmounted DASD volumes to be mounted automatically. This is the default.

FALSE

Prevents unmounted DASD volumes from being mounted automatically.

Examples

Mount DASD volumes that are not already mounted automatically:

```
AUTOMOUNT TRUE
```

Usage notes

- If AUTOMOUNT is allowed, FTP attempts to mount volumes, if necessary, to obtain temporary storage for load module transfers. Otherwise, the load module transfers fails with an `allocation failed` message if sufficient temporary storage is not already mounted and available.
- When transferring load modules, this parameter also controls whether or not the system attempts to mount additional temporary volumes if there is insufficient temporary DASD available and mounted to fulfill a load module transfer request.

AUTORECALL (FTP client and server) statement

Use the AUTORECALL statement to specify whether data sets that have been migrated by a storage manager, such as HSM, are recalled automatically.

Server

This setting applies when accessing files on the server's system.

Client

This setting applies when accessing files on the client's system.

Syntax**Parameters****TRUE**

Permits data sets migrated by the storage manager, such as HSM, to be recalled automatically. This is the default.

FALSE

Prevents migrated data sets from being recalled automatically.

Examples

Recall migrated HSM files automatically:

```
AUTORECALL TRUE
```

Usage notes

- Migrated data sets can still be deleted even though you specify `FALSE`.
- Partitioned data set members require the entire data set to be recalled.

AUTOTAPEMOUNT (FTP client and server) statement

Use the `AUTOTAPEMOUNT` statement to specify whether unmounted tapes are to be automatically allocated and mounted.

Server

This setting applies when accessing files on the server's system.

Client

This setting applies when accessing files on the client's system.

Syntax**Server syntax**

Client syntax

Parameters

TRUE

Permits unmounted tapes to be automatically allocated and mounted. This is the default for the server.

FALSE

Prevents unmounted tapes from being automatically allocated and mounted. This is the default for the client.

Examples

Automatically mount tape volumes that are not already mounted:

```
AUTOTAPEMOUNT TRUE
```

Do not automatically mount tape volumes that are not already mounted:

```
AUTOTAPEMOUNT FALSE
```

BANNER (FTP server) statement

Use the BANNER statement to identify the welcome banner to be displayed immediately after a client connects to the server.

Syntax

```
➤ BANNER — file-path ➤
```

Parameters

file-path

The file path is the z/OS UNIX absolute pathname or the fully qualified MVS data set name whose contents are displayed whenever a user connects to FTP. A z/OS UNIX pathname must begin with a slash (/) character. An MVS data set must not begin with a slash character.

Examples

To display the contents /etc/ftp.banner each time an FTP client connects to the FTP server, enter the following code in the server's FTP.DATA:

```
BANNER /etc/ftp.banner ; banner to be displayed for FTP
```

Usage notes

- If no BANNER statement is specified, no banner is displayed immediately after a new connection is established.
- One hundred lines of the file are displayed to the FTP client as 220 replies. If the file exceeds 100 lines, a final 220 reply is returned to the client indicating the banner was truncated.

- [“MVSINFO \(FTP server\) statement” on page 710](#)

BLKSIZE (FTP client and server) statement

Use the BLKSIZE statement to specify the block size of newly allocated data sets.

Server

This setting applies when creating files on the server's system (for example, with a PUT subcommand).

Client

This setting applies when creating files on the client's system (for example, with a GET subcommand).

Syntax

Parameters

size

Specifies the block size of newly allocated data sets. The valid range is 0 - 32 760. Specifying no value, or a value of 0 for block size, allows the block size from a model DCB data set or SMS dataclass to be used. The default block size is 6 233.

Examples

Set block size to 6 144 bytes:

```
BLKSIZE 6144
```

Allow the block size from a model DCB data set or SMS dataclass to be used:

```
BLKSIZE
```

Usage notes

- If you specify the BLKSIZE statement without a *size*, FTP does not specify the block size when allocating new data sets.
- The block size attribute can be obtained from an SMS data class using the DATACLASS configuration statement, from a model data set using the DCBDSN configuration statement, or from the BLKSIZE statement.
- Use BLKSIZE without a *size* if you have:
 - Specified a DATACLASS statement and want to use the blocksize from the data class, or
 - Specified a DCBDSN statement and want to use the blocksize from the model data set.

- If you specify a DATACLASS, a DCBDSN, and BLKSIZE without size, the value from the model data set is used.
- To override the blocksize attribute from the DATACLASS or DCBDSN settings:
 - Specify BLKSIZE with a value other than 0, or
 - Do not specify the BLKSIZE statement, and use the default.

Related topics

- See the information about storage management subsystem (SMS) in [z/OS Communications Server: IP Configuration Guide](#) for more information about specifying attributes when allocating new data sets.

- [“MGMTCLASS \(FTP client and server\) statement” on page 708](#)
- [“STORCLASS \(FTP client and server\) statement” on page 769](#)

BUFNO (FTP client and server) statement

Use the BUFNO statement to specify the number of access method buffers used when data is read from or written to a data set.

Server

This setting applies when reading or writing files on the server's system.

Client

This setting applies when reading or writing files on the client's system.

Syntax

Parameters

number

Specifies the number of buffers allocated. The valid range is 1 - 35. The default is 5.

CCONNTIME (FTP client) statement

Use the CCONNTIME statement to specify the amount of time that the FTP client waits after attempting to close a control connection before terminating it and reporting an error.

Syntax

Parameters

seconds

The number of seconds to which the timer is set. The valid range is 0 (CCONNTIME not used) or 15-86400. The default is 30 seconds.

Examples

```
CCONNTIME 60 ; wait 60 seconds
```

Related topics

See the FTP command `-- Entering the FTP environment` in the [z/OS Communications Server: IP User's Guide and Commands](#) for a description of the timeout parameter that can be used to change the timer when FTP is started.

CCTRANS (FTP client) statement

Use the CCTRANS statement to specify the SBCS translation table the FTP client uses for the control connection. The FTP client uses the translation table in the *user_id.dsn_qual.TCPXLBIN* data set. If that data set does not exist, the FTP client uses the *hlq.dsn_qual.TCPXLBIN* data set.

Syntax

➤ CCTRANS — *dsn_qual* ➤

Parameters

dsn_qual

The data set name qualifier for the translation table.

Examples

```
CCTRANS CTRL ; use USER33.CTRL.TCPXLBIN when ftp  
; is used by USER33
```

Usage notes

- CTRLCONN and CCTRANS are mutually exclusive statements. If both statements appear in the FTP.DATA file, CCTRANS is ignored.
- EXTENSION UTF8 and CCTRANS are mutually exclusive statements. If both statements appear in the FTP.DATA file, CCTRANS is ignored.

Related topics

- [“CTRLCONN \(FTP client and server\) statement” on page 660](#)
- [“EXTENSIONS \(FTP client and server\) statement” on page 682](#)

CCXLATE (FTP server) statement

Use the CCXLATE statement to specify a data set containing translate tables to be used for the control connection.

Syntax

➤ CCXLATE — *name* ➤

Parameters

name

Specifies a 1- to 8-character name corresponding to a data set containing translate tables.

FTP looks first for an environment variable called `_FTPXLATE_`*name*. If the environment variable exists, its value is used as the data set name

Restriction: The environment variable name must be all uppercase, although the CCXLATE parameter can be in mixed case.

If the environment variable does not exist, FTP looks for a data set called *hlq.name*.TCPXLBIN.

Examples

```
CCXLATE FRED
```

If environment variable `_FTPXLATE_FRED=FREDDYS.TABLES` is defined for the FTP server, this statement specifies that the translate tables in data set FREDDYS.TABLES should be used for the control connection.

If there is no such environment variable defined, this statement specifies that the translate tables data set *hlq.FRED*.TCPXLBIN should be used.

Usage notes

- CCXLATE and CTRLCONN are mutually exclusive statements. If both statements appear in your FTP.DATA file, CCXLATE is ignored.
- The CCXLATE statement (and its value) is not case sensitive but the name of the corresponding environment variable must be all uppercase or FTP does not recognize it.
- CCXLATE and EXTENSIONS UTF8 are mutually exclusive statements. If both statements appear in FTP.DATA, the CCXLATE statement is ignored.

Related topics

- [Appendix A, “Translation tables,” on page 1303](#)

- [“EXTENSIONS \(FTP client and server\) statement” on page 682](#)
- See [z/OS Communications Server: IP Configuration Guide](#) for more information about defining optional environment variables.
- To see the search order that determines the conversion for the control connection, see [“SBCS translation table hierarchy” on page 1303](#).
- [“XLATE \(FTP server\) statement” on page 791](#)

CHKCONFIDENCE statement (FTP client and server) statement

Use the CHKCONFIDENCE statement to tell the FTP client or server whether to check and report on the confidence level in the successful completion of file transfers. Checks include reporting a missing EOF marker in an inbound data set being transferred using record structure (STRUCTURE RECORD), or block mode (MODE B), or compress mode (MODE C) and verifying that the sender is still responding after the transfer.

Server

The server reports the confidence level after each transfer with FTP log message EZYFS86I and with a parameter passed to the FTPOSTPR user exit.

Client

The client reports the confidence level after each file transfer by issuing message EZA2108I.

Tips:

- If the MBREQUIRELASTEOL statement is set to FALSE, the confidence level reported when a multibyte file is received from the network without an EOL sequence in the last record is High.
- If the MBREQUIRELASTEOL statement is set to TRUE, the confidence level reported when a multibyte file is received from the network without an EOL sequence in the last record is Low.

Syntax

Parameters

TRUE

Perform the following checks and report any detected conditions that cast doubt on the successful completion of a transfer.

Use the following to make the determination:

- Whether a missing EOF marker condition is detected in an inbound STRUCTURE RECORD, or MODE B, or MODE C file
- Whether the sender fails to respond following any type of transfer
- Whether some other condition causes the transfer to fail or establish doubt about its completion

FALSE

Do not perform the checks or report on the confidence level in the successful completion of a transfer. This does not suppress reporting of error conditions.

Tips: Consider the following information when using the CHKCONFIDENCE statement:

- A missing EOF marker might or might not signal an error in the transmission, and it is reported only if no other problem is detected. A confidence level of NoEOF reflects a missing EOF marker. Any other problem changes the confidence level to Low.
- **FTP client**
 - See the message information for EZA2108I in [z/OS Communications Server: IP Messages Volume 1 \(EZA\)](#) for more information.
- **FTP server**
 - Either code FTPLOGGING TRUE in FTP.DATA or install the FTPOSTPR exit routine, to determine what confidence level the server assigns to each file transfer.
 - Message EZYFS86I is logged only when FTPLOGGING TRUE is coded in FTP.DATA. For additional information about EZYFS86I, see [z/OS Communications Server: IP Messages Volume 3 \(EZY\)](#).
 - The confidence level is passed to the FTPOSTPR exit. See [“The FTPOSTPR user exit” on page 593](#) for information about the FTPOSTPR exit routine.

Related topics

- [“FTPLOGGING \(FTP server\) statement” on page 688](#)

- [“The FTPOSTPR user exit” on page 593](#)

CHKPTFLUSH (FTP client) statement

If FTP saves checkpoint information in the checkpoint file or data set, z/OS might buffer the records in volatile storage instead of writing the data to storage media immediately. Use the CHKPTFLUSH statement to specify whether FTP forces z/OS to flush checkpoint information to storage media when each record is written, or allows z/OS to determine when checkpoints are flushed from volatile storage to storage media.

Guideline: When you allow z/OS to buffer checkpoint records, if you configure a large checkpoint interval and your operator cancels a file transfer operation when check pointing is active, you might lose most or all of the checkpoint data. This is because z/OS cannot flush buffered data to storage media when the FTP job is canceled. If you lose most or all of the checkpoint data, you cannot restart the file transfer from the point where it is interrupted. This is inefficient for long running file transfer operations. Code CHKPTFLUSH TRUE if this is a problem at your installation.

Syntax

Parameters

FALSE

z/OS is allowed to buffer checkpoint records in volatile storage when FTP saves them. z/OS determines when to flush buffered records to storage media. This is the default value.

TRUE

z/OS flushes checkpoint records to storage media as soon as FTP saves them.

Examples

z/OS flushes checkpoint records to storage media as soon as FTP saves them.

```
CHKPTFLUSH TRUE
```

Usage notes

None

Related topics

- [“CHKPTINT \(FTP client and server\) statement” on page 652](#)
- [“CHKPTPREFIX \(FTP client\) statement” on page 654](#)

CHKPTINT (FTP client and server) statement

Use the CHKPTINT statement to specify the number of records that can be sent between restart markers when transferring files in EBCDIC block mode or EBCDIC compress mode when the file type is SEQ.

Server

This setting applies when the server is the sending site (when the server is processing the RETR command).

The server ignores this setting when file type is not SEQ.

The server ignores this setting when it is retrieving data from a z/OS UNIX named pipe.

Requirement: Do not specify a nonzero value unless the client supports the checkpoint and restart function.

Client

This setting applies when the client is processing the APPEND, PUT, and MPUt subcommands. When you have configured RESTGET TRUE at the FTP client, this setting applies also to the GET and MGET subcommands. For more information about configuring RESTGET, see the locsite subcommand in the [z/OS Communications Server: IP User's Guide and Commands](#) and [“RESTGET \(FTP client\) statement”](#) on page 728.

The client ignores this setting when file type is not SEQ.

The client ignores this setting when you are transferring data to or from a z/OS UNIX named pipe.

Rule: Do not specify a nonzero value unless the FTP server supports the REStart command and checkpoint and restart function.

Syntax

Parameters

number

Used to determine when a restart marker is transmitted. The marker is transmitted after the specified number of records are sent.

If the *number* value is set to 0, checkpointing does not occur and no marker blocks are transmitted. The default is 0.

Examples

To send a restart marker of every 100000 records when the client is the sending site:

Client's FTP.DATA:

```
CHKPTINT 100000
```

To enable the checkpoint restart function when the server is the sending site, code the following statements in FTP.DATA:

Client's FTP.DATA:

```
RESTGET TRUE
```

Server's FTP.DATA:

```
CHKPTINT any non-zero value
```

Usage notes

- Specify a nonzero value to enable checkpointing during a file transfer. When checkpointing is enabled during a file transfer, you can restart a failed file transfer. To restart a failed transfer from the z/OS FTP

client, use the restart subcommand. See the restart subcommand information in [z/OS Communications Server: IP User's Guide and Commands](#).

- Client and server must both support the checkpoint/restart function. From the z/OS FTP client, you can enable or disable the client's support after logging in with a locsite subcommand. See [z/OS Communications Server: IP User's Guide and Commands](#) for more information.
- The z/OS FTP server allows you to change the value with a SITE CHKPTINT command. If only certain clients support the restart function, you should code CHKPTINT 0 in the server's FTP.DATA and direct the user to use a SITE command to set the server value after logging in. See the SITE command information in [z/OS Communications Server: IP User's Guide and Commands](#) for more information.

Related topics

- “CONDDISP (FTP client and server) statement” on page 658
- “CHKPTPREFIX (FTP client) statement” on page 654
- “RESTGET (FTP client) statement” on page 728
- “RESTPUT (FTP server) statement” on page 728

CHKPTPREFIX (FTP client) statement

Use the CHKPTPREFIX statement to specify the high level qualifier (*hlq*) for the FTP client checkpoint file. The FTP client uses the *hlq* to determine the name of the local checkpoint data set or file.

Syntax

Parameters

HOME

If the client is running in the z/OS UNIX shell, the *hlq* is the current path and the name of the checkpoint file is *current_path*/ftp.chkpoint. Otherwise, the *hlq* is the TSO prefix and the checkpoint data set is named *tso_prefix*.FTP.CHKPOINT.

This is the default.

USERID

Use the user ID associated with the address space where the FTP command is issued as the *hlq* for the checkpoint data set. The name of the data set is *userID*.FTP.CHKPOINT.

LOCAL

Use the local working directory (*local_dir*) as set by the lcd subcommand. If the directory is a z/OS UNIX directory, the checkpoint file is *local_dir*/ftp.chkpoint. If the directory is a partitioned data set, the checkpoint data set name is *local_dir*(CHKPOINT). Otherwise, the checkpoint data set is *local_dir*.FTP.CHKPOINT.

Examples

To use the user ID, use the following code:

```
CHKPTPREFIX  USERID
```

Usage notes

None

Related topics

- [“CHKPTINT \(FTP client and server\) statement” on page 652](#)
- [“RESTGET \(FTP client\) statement” on page 728](#)

CIPHERSUITE (FTP client) statement

Use the CIPHERSUITE statement to specify the name of a cipher algorithm that is used during the TLS handshake. Indicates the client’s preference of cipher algorithms.

Note: This parameter is only meaningful if TLSMECHANISM FTP is specified. If TLSMECHANISM ATTLS is specified, then the cipher suites must be configured in the AT-TLS policy.

Syntax

➤ CIPHERSUITE — *name* ➤

Parameters

name

The name of the cipher algorithm. The following values are allowed *name* values:

- SSL_NULL_MD5
- SSL_NULL_SHA
- SSL_RC4_MD5_EX
- SSL_RC4_MD5
- SSL_RC4_SHA
- SSL_RC2_MD5_EX
- SSL_DES_SHA
- SSL_3DES_SHA
- SSL_AES_128_SHA
- SSL_AES_256_SHA

The *name* can be interpreted as follows:

```
SSL_<cipher>_<cipher hash>[_EX]
```

<cipher> specifies one of the following encryption algorithms:

AES_128

128-bit AES; Advanced Encryption Standard is established by the National Institute of Standards and Technology (NIST).

AES_256

256-bit AES; Advanced Encryption Standard is established by the National Institute of Standards and Technology (NIST).

RC2

Block cipher developed at RSA Data Security

RC4

Stream cipher developed at RSA Data Security

DES

Digital Encryption Standard (56 bits of security)

3DES

Digital Encryption Standard (168 bits of security)

NULL

No algorithm is used. NULL indicates that there is no key exchange.

<*cipher hash*> specifies one of the following authentication algorithms:

MD5

Algorithm that converts to fixed size (16 bytes)

SHA

Secure Hash Algorithm that converts to a 20-byte output

The suffix `_EX` indicates that the corresponding cipher suite is exportable.

Restrictions:

- The following list shows the subject to export restrictions and might not be available outside of the United States:
 - `SSL_3DES_SHA`
 - `SSL_RC4_SHA`
 - `SSL_RC4_MD5`
 - `SSL_AES_128_SHA`
 - `SSL_AES_256_SHA`
- Only RSA key exchange is supported.

Examples

To indicate that you want to use the 3DES encryption and SHA authentication as your first choice, and that RC4 encryption and MD5 authentication are your second choice, code the following examples:

```
CIPHERSUITE SSL_3DES_SHA
```

```
CIPHERSUITE SSL_RC4_MD5
```

Authorization

- Multiple CIPHERSUITE statements can be coded in the FTP.DATA file.
- The client specifies the list of encryption types that it supports. The client and server negotiate which of the available ciphers is used for the data encryption by specifying the desired ciphers in order of preference. The actual cipher used is the best match between what the server supports and what the client requests. If the server does not support any of the ciphers that the client requests, the TLS handshake fails and the connection is closed. See the [z/OS Cryptographic Services System SSL Programming](#) for a list of ciphers that are included in the base product.
- The CIPHERSUITE statements are used by the FTP client when meeting the following 2 requirements:
 - the `SECURE_MECHANISM` TLS and `TLSMECHANISM` FTP statements are coded
 - the FTP client is started with either the `-a TLS` or the `-r TLS` start parameter

Related topics

- [“SECURE_MECHANISM \(FTP client\) statement” on page 744](#)
- [“TLSMECHANISM \(FTP client and server\) statement” on page 772](#)
- See [z/OS Communications Server: IP Configuration Guide](#) for more information about [SSL/TLS security](#), [key rings](#), and [certificates](#).

CLIENTERRCODES (FTP client) statement

Use the CLIENTERRCODES (FTP client) to specify whether FTP return codes are to be converted to client error codes.

Syntax

Parameters

FALSE

Issue standard FTP return codes. See the FTP return codes topic in [z/OS Communications Server: IP User's Guide and Commands](#) for a complete description of standard FTP return codes.

TRUE

Convert FTP return codes into a set of codes defined in FTP client error codes in the [z/OS Communications Server: IP User's Guide and Commands](#).

EXTENDED

Convert FTP return codes into the client error code (as would be returned for TRUE) concatenated with the subcommand number. See the FTP client error codes extended topic of the [z/OS Communications Server: IP User's Guide and Commands](#) for more information.

Examples

```
CLIENTERRCODES EXTENDED ; request extended error codes
```

Usage notes

When the FTP client is invoked from the FTP client application programming Interface (API), the value on the CLIENTERRCODES statement does not affect the operation of the client, as all return codes including client error codes are returned to the application.

Related topics

- [“LOGCLIENTERR \(FTP client\) statement” on page 702](#)
- [FTP client error logging in z/OS Communications Server: IP User's Guide and Commands](#)
- For more information, see [using the FTP client API trace in z/OS Communications Server: IP Programmer's Guide and Reference](#).

CLIENTEXIT (FTP client) statement

Use the CLIENTEXIT statement to specify whether the FTP client exits with a nonzero MVS return code for certain FTP errors.

Syntax

Parameters

FALSE

FTP client does not exit with a nonzero MVS return code when certain errors occur.

Result: Starting the FTP client with the EXIT parameter can override CLIENTEXIT FALSE.

TRUE

FTP client exits with a nonzero MVS return code when certain errors occur.

Result: Coding CLIENTEXIT TRUE is equivalent to starting the FTP client with the EXIT parameter. See [FTP command -- Entering the FTP environment in the z/OS Communications Server: IP User's Guide and Commands](#) for more information about the EXIT parameter.

Examples

```
CLIENTEXIT TRUE ; FTP client will exit when an error occurs
                  ; even though EXIT is not coded specified when
                  ; starting the FTP client.
```

Related topics

- [“CLIENTERRCODES \(FTP client\) statement” on page 657](#)
- [FTP command -- Entering the FTP environment in the z/OS Communications Server: IP User's Guide and Commands](#)
- [FTP return codes in the z/OS Communications Server: IP User's Guide and Commands](#)

CONDDISP (FTP client and server) statement

Specify whether to keep or delete a new data set, z/OS UNIX file, or z/OS UNIX named pipe when an FTP file transfer ends prematurely.

Server

This setting applies when writing new files, named pipes, or data sets on the server system (for example, with a PUT subcommand).

Client

This setting applies when writing new files, named pipes, or data sets on the client system (for example, with a GET subcommand).

Syntax

Parameters

CATLG

Specifies that new data sets, z/OS UNIX files, and z/OS UNIX named pipes are kept when an FTP file transfer ends prematurely. For MVS data set transfers, the data set is also cataloged. This is the default.

DELETE

Specifies that new data sets, z/OS UNIX files, and z/OS UNIX named pipes are deleted when a file transfer ends prematurely.

Examples

Specify that a new data set, z/OS UNIX file, or named pipe is deleted when a file transfer ends prematurely:

```
CONDDISP DELETE
```

Rules:

- DELETE is ignored if the file transfer ended prematurely because FTP was stopped.
- DELETE is ignored if a checkpoint marker is received.
- If you are running a job scheduling program that detects files as they are cataloged and then schedules a subsequent job for processing, the job scheduler must take into account that setting CONDDISP=DELETE causes FTP to delete and uncatalog the data set when the file transfer fails. For generation data groups, the following situations might occur:
 - FTP intends to create a new GDG(+1) and generates GDG.G00023V00.
 - The transfer of this data set fails, and the GDG.G00023V00 data set is deleted and uncataloged.
 - A follow-on reference for the current GDG, for example, GDG(0), would cause the data set GDG.G00022V00 to be accessed and old data to be processed.
- If you are transferring a physical sequential data set with the MVSGet or MVSPut subcommand, the data set that is created is disposed according to the CONDDISP configuration if the transfer ends prematurely. However, if you are transferring a PDS or library data set, the data set that is created is deleted regardless of the CONDDISP configuration if the transfer ends prematurely.

Related topic

- [“CHKPTINT \(FTP client and server\) statement” on page 652](#)

CTRL_TLS_SESSTCKTS (FTP server) statement

Use the CTRL_TLS_SESSTCKTS statement to specify whether the FTP server should control the sending of TLSv1.3 session tickets for session reuse or allow session tickets to be sent transparently by AT-TLS.

Restrictions:

- This parameter is only applicable when TLSv1.3 is negotiated to protect the FTP control and data connections.
- For the FTP server to control the sending of TLSv1.3 session tickets, the AT-TLS FTP server rule must have session tickets enabled and automatic session tickets disabled. By default, automatic session tickets are enabled.
 - To enable session tickets for the server, use the GSK_SESSION_TICKET_SERVER_ENABLE and GSK_V3SIDCACHE_SIZE parameters on the AT-TLS TTLSGskAdvancedParms policy statement.
 - To disable automatic session tickets, the GSK_SESSION_TICKET_SERVER_COUNT parameter on the TTLSGskAdvancedParms policy statement must be set to 0.

See the “[TTLSGskAdvancedParms statement](#)” on page 933 for additional information on these parameters.

Results:

- If the AT-TLS FTP server rule has session tickets disabled (GSK_SESSION_TICKET_SERVER_ENABLE Off or GSK_V3_SIDCACHE_SIZE 0), TLSv1.3 session tickets are not sent by the server. An FTP data connection is unable to reuse the control connection's secure session.
- If the AT-TLS FTP server rule has automatic session tickets enabled (GSK_SESSION_TICKET_SERVER_COUNT > 0), FTP is not able to control the sending of TLSv1.3 session tickets. The TLS negotiation continues with AT-TLS controlling the automatic sending of TLSv1.3 session tickets.

Tip: When TLSv1.3 session tickets are sent transparently by AT-TLS, initial session tickets for both the control and data connections are sent before System SSL returns control from each TLS handshake. Problems can arise if a TLS client sends data and then immediately closes the connection. Using CTRL_TLS_SESSTCKTS TRUE results in the sending of a session ticket on the control connection for use with the TLS negotiation of the data connection. This can prevent potential failures due to timing issues.

Syntax

TRUE

The FTP server controls the sending of TLSv1.3 session tickets for session reuse if the AT-TLS FTP server rule has session tickets enabled with automatic session tickets disabled.

FALSE

The sending of TLSv1.3 session tickets is handled transparently by AT-TLS

Examples

To request that the FTP server control the sending of session tickets for TLSv1.3 session reuse:

```
CTRL_TLS_SESSTCKTS TRUE
```

CTRLCONN (FTP client and server) statement

This statement defines the ASCII code page to be used for the control connection.

Server

Specifies the code page used by the server.

Client

Specifies the code page used by the client.

Syntax

Parameters

7BIT

Indicates that the 7-bit ASCII code page is to be used. 7BIT is the default if CTRLCONN is not used and no TCPXLBIN data set is found.

iconv_ascii

A name recognized by iconv to indicate an ASCII code page.

FTP_STANDARD_TABLE

Indicates that the FTP internal tables, which are the same as the tables that are shipped in TCPXLBIN(STANDARD), are to be used.

Examples

```
CTRLCONN IBM-858
```

Usage notes

- 7BIT or an *iconv_ascii* name can be entered in lowercase or uppercase.
- To see the search order that determines the [code page conversion](#) for the control connection, see [z/OS Communications Server: IP Configuration Guide](#).
- EXTENSIONS UTF8 and CTRLCONN are mutually exclusive statements. If both statements are coded in FTP.DATA, CTRLCONN is ignored.

Related topics

- “CCXLATE (FTP server) statement” on [page 649](#)
- “EXTENSIONS (FTP client and server) statement” on [page 682](#)
- For the code pages supported, see code set converters in the [z/OS XL C/C++ Programming Guide](#).

DATACLASS (FTP client and server) statement

Use the DATACLASS statement to specify the SMS-managed data class as defined by your organization for the FTP server.

Server

This setting applies when creating files on the server's system (for example, with a PUT subcommand).

Client

This setting applies when creating files on the client's system (for example, with a GET subcommand).

Syntax

➤ DATACLASS — *class* ➤

Parameters

class

The SMS-managed data class as defined by your organization. There is no default.

Examples

Use the SMS data class SMSDATA when allocating new data sets:

```
DATACLASS SMSDATA
```

Results:

- If you code any of the following FTP.DATA statements or let FTP assign them default values, the configured values or default values override the values specified in the SMS DATACLASS:
 - BLKSIZE
 - DIRECTORY
 - LRECL
 - PRIMARY
 - RECFM
 - RETPD
 - SECONDARY

Guideline: To prevent these statements from overriding the values specified in the SMS DATACLASS, perform one of the following actions:

- Code the statements with no parameters.
- For client allocations, use the LOCSite subcommand to configure these options with no values before allocating a new data set.
- For server allocations, use the SItE subcommand or the server SITE command to configure these options with no values before allocating a new data set.
- If you code the following statements in FTP.DATA with the default value or let FTP assign the default value, FTP will use the value in the SMS DATACLASS.
 - DNSTYPE
 - EATTR

If the SMS DATACLASS does not specify the value, FTP will use the system default.

Guideline: To override the SMS DATACLASS value and the system default value, perform one of the following actions:

- Code statements in FTP.DATA with the values that you want.
- For client allocations, use the LOCSite subcommand to configure the values that you want.
- For server allocations, use the SItE subcommand or the server SITE command to configure the values that you want.
- The PDSTYPE FTP.DATA statement has no default values. If you code this statement in FTP.DATA with parameters, the configured value overrides the value specified in the SMS DATACLASS.

Guideline: To prevent this statement from overriding the value specified in the SMS DATACLASS, perform one of the following actions:

- Code the statement with no parameter.
- Remove the statement from FTP.DATA.
- For client allocations, use the LOCSite subcommand to configure this option with no value before allocating a new data set.
- For server allocations, use the SItE subcommand or the server SITE command to configure this option with no value before allocating a new data set.
- If you specify the DCBDSN statement, the LRECL, RECFM, BLKSIZE, and RETPD (if specified) of the DCBDSN data set override the values specified in the SMS DATACLASS.

Guideline: To prevent the DCBDSN values from overriding the values specified in the SMS DATACLASS, perform one of the following actions:

- Code statements in FTP.DATA for LRECL, RECFM, BLKSIZE, and RETPD with no keyword values.
- For client allocations, use the LOCSite subcommand to configure these options with no values before allocating a new data set.

- For server allocations, use the SItE subcommand or the server SITE command to configure these options with no values before allocating a new data set.
- If you specify the MGMTCLASS statement and the requested management class specifies a retention period, the RETPD value of the management class might override the RETPD value of DATACLASS.

- See the information about storage management subsystem (SMS) in [z/OS Communications Server: IP Configuration Guide](#) for more information about specifying attributes when allocating new data sets.

DATACTIME (FTP client) statement

Use the DATACTIME statement to specify the number of seconds that the FTP client waits after attempting to send or receive data before terminating the connection and reporting an error to the user. The default is 120. The valid range for DATACTIME is 0 (DATACTIME not used) or 15-86 400.

Syntax

Parameters

seconds

The number of seconds to which the timer is set. The valid range is 0 (DATACTIME not used) or 15-86 400. The default is 120 seconds.

Examples

```
DATACTIME 160 ; wait 160 seconds
```

Related topics

See the FTP command and the FTP environment information in [z/OS Communications Server: IP User's Guide and Commands](#).

DATAKEEPAIVE (FTP client and server) statement

Use the DATAKEEPAIVE statement to specify the data connection keepalive timer.

Results:

- The DATAKEEPAIVE statement overrides the keepalive timer value that you configured in the PROFILE.TCPIP file.
- The keepalive timer causes TCP/IP to send a keepalive packet on the data connection when the connection is idle for the length of time specified in the DATAKEEPAIVE statement. Keepalive packets prevent the data connection from timing out as a result of long periods of inactivity.

Server

Specifies how often the server sends a keepalive packet.

Client

Specifies how often the client sends a keepalive packet.

Syntax

Parameters

seconds

The number of seconds of inactivity that passes before a keepalive packet is sent out on the FTP data connection. Valid values are 0 (DATAKEEPAIVE not used) or 60 - 86 400. The default is 0.

Rule: If you specify 0 seconds, the DATAKEEPAIVE timer is disabled, and the only keepalive packets that flow on the data connection are controlled by the interval for the keepalive packets that you configured in the stack.

Guidelines:

- Use the DATAKEEPAIVE statement if the DSWAITTIME configuration option is a value other than 0.
- Use the DATAKEEPAIVE statement for FILETYPE=JES transfers.

Examples

Use the following code to set the data connection keepalive timer to 60 seconds:

```
DATAKEEPAIVE 60
```

Related topics

- [“DSWAITTIME \(FTP client and server\) statement” on page 674](#)
- [“FTPKEEPAIVE \(FTP client and server\) statement” on page 687](#)

DATATIMEOUT (FTP server) statement

Use the DATATIMEOUT statement to specify the length of time to wait for the send to complete before the connection is aborted.

Syntax

Parameters

seconds

Used to determine when to abort the connection if a `send()` or `recv()` is not completed or if a passive socket was opened, but never completed by the remote client. Allowed values are 0 - 86 400. The default is 300 seconds.

Specifying 0 indicates no timeout value is used, and the transfer does not time out.

Examples

To check for send completion at 30 seconds:

```
DATETIMEOUT 30
```

Usage notes

The DATETIMEOUT timer is set when the FTP server does a `send()` or `recv()` call to TCP/IP or when a passive data connection is detected, and the server must wait for the client to complete the session. If the process does not complete within the timer value, the connection is aborted.

DB2 (FTP client and server) statement

Use the DB2 statement to specify the name of the Db2 subsystem.

Server

This setting applies when FILETYPE=SQL and a GET subcommand is processed.

Client

This setting applies when FILETYPE=SQL and a PUT subcommand is processed.

Syntax

Parameters

subsystem_name

The name of the Db2 subsystem. The default name is DB2.

Examples

Set the Db2 subsystem name to DB2X:

```
DB2 DB2X
```

Related topics

- [“DB2PLAN \(FTP client and server\) statement” on page 666](#)

- See the Db2 SQL queries information in [z/OS Communications Server: IP User's Guide and Commands](#).
- See the information about the SQL query function in [z/OS Communications Server: IP Configuration Guide](#).

DB2PLAN (FTP client and server) statement

Use the DB2PLAN statement to specify the Db2 plan to be used by the FTP server.

Server

This setting applies when FILETYPE=SQL and a GET subcommand is processed.

Client

This setting applies when FILETYPE=SQL and a PUT subcommand is processed.

Syntax

Parameters

plan_name

The name of the Db2 plan bound in the Db2 subsystem.

Examples

Set the plan name to FTPPLAN:

```
DB2PLAN    FTPPLAN
```

Related topic

- [“DB2 \(FTP client and server\) statement” on page 665](#)

DBSUB (FTP client and server) statement

Use the DBSUB statement in server and client FTP.DATA to specify whether substitution is allowed for double-byte data that cannot be translated. The site and locsite subcommands are also available to set this keyword.

Server

Specifies whether double-byte substitution is allowed on the server's system.

Client

Specifies whether double-byte substitution is allowed on the client's system.

Syntax

Parameters

FALSE

Substitution is not allowed for double-byte character translation. This causes a data transfer failure if a character cannot be mapped during the transfer. This is the default value.

TRUE

Substitution is allowed for double-byte character translation.

Examples

To allow substitution for double-byte character translation, use the following code:

```
DBSUB TRUE
```

DCBDSN (FTP client and server) statement

Use the DCBDSN statement to specify an MVS data set to be used as a model for allocation of new data sets.

Server

This setting applies when creating files on the server's system (for example, with a PUT subcommand).

Client

This setting applies when creating files on the client's system (for example, with a GET subcommand).

Syntax

► DCBDSN — *name* ◄

Parameters

name

The name of the data set to be used as a model for allocation of new data sets created with a STOR or MKDIR command.

Requirement: This data set name must be a fully qualified MVS data set name; z/OS UNIX file names are not allowed.

There is no default.

Usage notes

- If specified or set to the default value, the following FTP.DATA statements, SITE command parameters, or locsite subcommand parameters override the DCB values from the model data set:
 - BLKSIZE
 - LRECL
 - RECFM
 - RETPD
- If you specify the MGMTCLASS statement, the retention period from the model data set can be overridden by the retention period specified by the SMS management class.
- When using a model DCB at the server, SENDSITE must be toggled off at the client. Otherwise, the SITE information sent automatically by the client overrides the value provided by the model DCB.
- BLKSIZE can also be specified with no value to allow the attributes from the model DCB to be used:

```
DCBDSN model.dcb
BLKSIZE
LRECL 0
RECFM
RETPD
```

Related topics

- “BLKSIZE (FTP client and server) statement” on page 647

- “MGMTCLASS (FTP client and server) statement” on page 708
- “RECFM (FTP client and server) statement” on page 723
- “RETPD (FTP client and server) statement” on page 729
- See the information about storage management subsystem (SMS) in [z/OS Communications Server: IP Configuration Guide](#) for more information about specifying attributes when allocating new data sets.

DCONNTIME (FTP client and server) statement

Use the DCONNTIME statement to define the amount of time that FTP waits attempting to close a data a data transfer before terminating the connection and reporting an error.

Server

This setting specifies the time that the server waits on the client.

Client

This setting specifies the time that the client waits on the server.

Syntax

Parameters

seconds

The number of seconds FTP waits to receive notification that the data connection is closing. The valid range is 0 (DCONNTIME not used) or 15-86400. The default is 120.

Examples

Set the timer to 600 seconds:

```
DCONNTIME 600
```

Usage notes

If you specify 0 seconds, the DCONNTIME timer is disabled and FTP receives the FIN before closing the data connection.

DEBUG (FTP client and server) statement

Use the DEBUG statement to activate a specific trace type.

Restriction: Only one trace type can be activated for a DEBUG statement.

Server

Traces are recorded on server's system for server processing.

Client

Traces are recorded on client's system for client processing.

Syntax

➤ DEBUG — *parameter* ➤

Parameters

FLO

The FLO trace shows the flow of control within FTP. It is used to show which services of FTP are used for an FTP request.

CMD

The CMD trace shows each command and the parsing of the parameters for the command.

PAR

The PAR trace shows details of the FTP command parser. It is useful when debugging problems with the processing of command parameters.

INT

The INT trace shows the details of the initialization and termination of the FTP session.

ACC

The ACC trace shows the details of the login process.

UTL

The UTL trace shows the processing of utility functions such as CD and SITE.

FSC(n)

The FSC trace shows details of processing the file services server commands APPE, STOR, STOU, RETR, DELE, RNFR, and RNTD. For the client, it shows the details for subcommands, such as GET, PUT, APPEND, DELETE, and RENAME. This trace allows you to specify levels of detail for the trace points. The level one tracing specified by entering FSC or FSC(1) is the level typically used unless more data is requested by the TCP/IP service group. *n* can be an integer between 1 and 8.

SEC

The SEC trace shows the processing of security functions such as TLS and GSSAPI negotiations.

SOC(n)

The SOC trace shows details of the processing during the setup of the interface between the FTP application and the network as well as details of the actual amounts of data that are processed. This trace allows you to specify levels of detail for the trace points. The level one tracing that is specified by entering SOC or SOC(1) is the level typically used unless more data is requested by the TCP/IP service group. *n* can be an integer between 1 and 8.

JES

The JES trace shows details of the processing for JES requests (that is, requests when SITE FILETYPE=JES is in effect).

Restriction: This parameter applies to the server only.

SQL

The SQL trace shows details of the processing for SQL requests (that is, requests when SITE or LOC SITE FILETYPE=SQL is in effect).

ALL

This value is used to set all of the trace points. Both the FSC and the SOC trace are set to level one when the ALL parameter is processed.

BAS

This value is used to set a select group of traces that offer the best overall details without the more excessive tracing some of the other traces provide. Specifying this value is the same as the following values:

- DEBUG CMD
- DEBUG INT
- DEBUG FSC
- DEBUG SOC

USERID (*filter_name*)

This parameter is used to filter the trace for user IDs matching the *filter_name* pattern. If the user ID matches the filter at the time the client logs in, tracing options are set to the current value of the options. Otherwise, no tracing options are set. The client can use the SITE command to set options after login if the initial ones are not appropriate. An example for the USERID filter is:

```
DEBUG USERID(USER33)
```

which activates the trace for a user if the user ID is USER33.

Restriction: This parameter applies to the server only.

IPADDR (*filter*)

This parameter is used to filter the trace for IP addresses matching the filter pattern. If the IP address matches the filter at the time the client connects, tracing options are set to the current value of the options. Otherwise, no tracing options are set. The client might use the SITE command to set options after connect if the initial ones are not appropriate. Examples of the IPADDR(*filter*) are:

```
DEBUG IPADDR(9.67.113.57)
DEBUG IPADDR(FEDC:BA98:7654:3210:FEDC:BA98:7654:3210)
```

The first example activates the trace for a client whose IP address is 9.67.113.57; the second activates the trace for a client whose IP address is FEDC:BA98:7654:3210:FEDC:BA98:7654:3210. If the filter is an IPv4 address, submasking can be indicated by using a slash followed by a dotted decimal submask. For example, 192.48.32.0/255.255.255.0 allows addresses from 192.48.32.00 to 192.48.32.255.

If the filter is an IPv6 address, network prefixing can be indicated by using a slash followed by a network prefix. For example, use FEDC:BA98::0/32 to indicate the prefix: FEDCBA98.

Restriction: This parameter applies to the server only.

DEBUGONSITE (FTP server) statement

Use the DEBUGONSITE statement to specify whether the FTP server accepts a SITE DEBUG command to change the general tracing options for the FTP session.

Syntax

Parameters

TRUE

The server accepts a SITE DEBUG command from the client to change the general trace options for the current session.

FALSE

The server does not accept a SITE DEBUG command from the client. This is the default.

Related topics

- [“DEBUG \(FTP client and server\) statement” on page 668](#)
- See [z/OS Communications Server: IP User's Guide and Commands](#) for more information about the [SITE subcommand](#).

DEST (FTP server) statement

Use the DEST statement to specify the NJE destination to which the files are routed when the server receives a STOR, STOU, or APPE command. Using the DEST statement allows you to send data sets to other users on machines connected on a network job entry (NJE) network rather than storing them at the server.

Syntax

➤ DEST — *destination* ➤

Parameters

destination

The NJE destination to which the files are routed when the server receives a STOR, STOU, or APPE command. The format for *destination* should be one of the following:

- userID@nodeID
- nodeID.userID
- nodeID
- DestID

There is no default.

Examples

Send files to user USER14 at system MVS1 instead of storing them in the server file system:

```
DEST USER14@MVS1
```

DIRECTORY (FTP client and server) statement

Use the DIRECTORY statement to specify the number of directory blocks to be allocated for the directory of a PDS.

Server

This setting applies when creating files on the server's system (for example, with a PUT subcommand).

Client

This setting applies when creating files on the client's system (for example, with a GET subcommand).

Syntax

Parameters

size

The number of directory blocks to be allocated for the directory of a PDS. The valid range is 1 - 16 777 215 blocks (the operating system maximum). The default is 27.

Examples

Allocate a PDS with 15 directory blocks:

```
Directory 15
```

Specify `DIRECTORY` with no value to allow the directory information from an SMS dataclass to be used:

```
DIRECTORY
```

Usage notes

- If you specify no value for the *size*, FTP does not specify the number of directory blocks to be allocated for the directory of a PDS.
- You should specify no value for the *size* if the `DATACLASS` statement is specified and the directory from the SMS data class is to be used.

Related topics

- See the storage management subsystem (SMS) information in [z/OS Communications Server: IP Configuration Guide](#) for more information about specifying attributes when allocating new data sets.

DIRECTORYMODE (FTP client and server) statement

Use the `DIRECTORYMODE` statement to specify whether only the data set qualifier immediately below the current directory is treated as an entry in the directory or if all data set qualifiers below the current directory are treated as entries in the directory.

Server

This setting applies when issuing the `MGET`, `LS`, `DIR`, and `MDELETE` subcommands.

Client

This setting applies when issuing the `MPUT` subcommand.

Syntax

Parameters

TRUE

Specifies that only the data set qualifier immediately below the current directory is treated as an entry in the directory.

FALSE

Specifies that all data set qualifiers below the current directory are treated as entries in the directory. This is the default.

Examples

If DIRECTORYMODE TRUE:

```
ftp> ls
200 Port request OK.
125 List started OK.
AREADME
BAILEY
BAILEY.MSYS.SPX001.I2.TEMP
BAILEY.TRANS
EZACIMJA
ISPF.ISPROF
XMLS
XX.AREADME
250 List completed successfully.
101 bytes received in 0.03 seconds (3.37 Kbytes/sec)
```

If DIRECTORYMODE FALSE:

```
ftp> ls
200 Port request OK.
125 List started OK.
AREADME
BAILEY
BAILEY
EZACIMJA
ISPF
XMLS
XX
250 List completed successfully.
51 bytes received in 0.03 seconds (1.07 Kbytes/sec)
```

DSNTYPE (FTP client and server) statement

Use the DSNTYPE statement to specify whether FTP creates local physical sequential data sets as physical sequential basic format data sets or physical sequential large format data sets. You can also use the SItE and LOCStE subcommands to set this keyword.

Server

This setting applies when creating data sets on the server's system.

Client

This setting applies when creating data sets on the client's system.

Syntax

Parameters

BASIC

Allocates physical sequential data sets as physical sequential basic format data sets.

LARGE

Allocates physical sequential data sets as physical sequential large format data sets.

SYSTEM

Allocates physical sequential data sets with the SMS data class value, or the system default value.

Examples

To allocate new physical sequential data sets as physical large format data sets, code the following statement in FTP.DATA:

```
DSNTYPE LARGE
```

Related topics:

- See the storage management subsystem (SMS) information in the [z/OS Communications Server: IP Configuration Guide](#) for more information about specifying attributes when allocating new data sets.

- [“RETPD \(FTP client and server\) statement” on page 729](#)
- [“SECONDARY \(FTP client and server\) statement” on page 735](#)
- [“SPACETYPE \(FTP client and server\) statement” on page 765](#)
- [“VOLUME \(FTP client and server\) statement” on page 788](#)

DSWAITTIME (FTP client and server) statement

Use the DSWAITTIME statement to specify the number of minutes that FTP tries to access an MVS data set that could not be obtained because another job or process was holding the data set. FTP tries to access the data set approximately every minute for the number of minutes specified in the DSWAITTIME statement.

Restriction: The DSWAITTIME statement does not support tape data sets.

Server

Specifies how many minutes the server tries to access to MVS data set.

Client

Specifies how many minutes the client tries to access to MVS data set.

Rule: The FTP server reply that displays the holder and other useful information related to the MVS data set is issued only when REPLYSECURITYLEVEL is 0.

Syntax

Parameters

minutes

The number of minutes to wait for an MVS data set to become available. Valid values are 0 (DSWAITTIME not used) or 1 - 14400. The default is 0.

Rule: If DSWAITTIME is set to 0, the timer is not set, and only one attempt is made to access an MVS data set.

Guidelines:

- The FTP server ignores the DSWAITTIME configuration option for RENAME FROM (RNFR), RENAME TO (RNT0), and DELETE (DELE) commands.
- If the DSWAITTIME configuration option is not 0, also specify the DATAKEEPLIVE configuration option.
- If you experience control connection timeouts while the server is waiting for access to an MVS data set, try configuring a nonzero value for FTPKEEPLIVE at the client or the server. If keepalive packets do not prevent FTP control connection timeouts, configure a smaller DSWAITTIMEREPLY value.

Examples

Use the following code to set the data set wait time to 10 minutes:

```
DSWAITTIME 10
```

Related topics

- [“DSWAITTIMEREPLY \(FTP server\) statement” on page 675](#)
- [“DATAKEEPLIVE \(FTP client and server\) statement” on page 664](#)
- [“FTPKEEPLIVE \(FTP client and server\) statement” on page 687](#)
- [“REPLYSECURITYLEVEL \(FTP server\) statement” on page 727](#)

DSWAITTIMEREPLY (FTP server) statement

Use the DSWAITTIMEREPLY statement to specify how often to send the following reply message to the client while the FTP server is waiting for access to an MVS data set.

```
125- Data set access will be retried in 1 minute intervals - number attempts  
remaining
```

Results:

- The server always issues the following reply at one-minute intervals while waiting for access to a data set for the amount of time specified by the DSWAITTIME configuration option.

```
125- FTP Server unable to obtain usage use of data set
which is held by asid jobname accessmode on qname
```

By default, the server also sends the following reply to the client at one-minute intervals.

```
125- Data set access will be retried at 1 minute intervals - number attempts
remaining
```

Set the DSWAITTIMEREPLY value to a number smaller than 60 to cause the server to send this reply more frequently.

- The DSWAITTIMERREPLY value is applied only when you have configured a DSWAITTIME value that is greater than zero.

Tip: Coding a DSWAITTIMEREPLY value that is smaller than 60 can prevent an FTP client connection from timing out while the server is waiting for a data set.

Syntax

Parameters

seconds

The number of seconds between reply messages that the server sends to the client while it is waiting for access to an MVS data set. The valid range is 15 - 60. The default value is 60. The reply message that is sent:

```
125- Data set access will be retried at 1 minute intervals - number attempts
remaining
```

Examples

In this example, the DSWAITTIMEREPLY value is 30. The following reply message is issued every 30 seconds:

```
125- Data set access will be retried at 1 minute intervals - number attempts
remaining
```

If the DSWAITTIMEREPLY value is 30, the following would be the actual output:

```
125- FTP Server unable to obtain EXCLUSIVE use of
USER.TEST.DATA which is held by: 0035 USER2
EXCL on SYSDSN
125- Data set access will be retried in 1 minute
intervals - 3 attempts remaining
125- Data set access will be retried in 1 minute
intervals - 3 attempts remaining
125- FTP Server unable to obtain EXCLUSIVE use of
USER.TEST.DATA which is held by: 0035 USER2
EXCL on SYSDSN
125- Data set access will be retried in 1 minute
intervals - 2 attempts remaining
125- Data set access will be retried in 1 minute
intervals - 2 attempts remaining
125- FTP Server unable to obtain EXCLUSIVE use of
USER.TEST.DATA which is held by: 0035 USER2
EXCL on SYSDSN
125- Data set access will be retried in 1 minute
intervals - 1 attempts remaining
125- Data set access will be retried in 1 minute
intervals - 1 attempts remaining
125- FTP Server unable to obtain EXCLUSIVE use of
USER.TEST.DATA which is held by: 0035 USER2
```

- [“FTPKEEPALIVE \(FTP client and server\) statement” on page 687](#)

DUMP (FTP client and server) statement

Use the DUMP statement to activate an extended trace.

Restriction: Only one dump parameter can be specified for a DUMP statement.

Server

Extended traces are recorded on server's system for server debugging.

Client

Extended traces are recorded on client's system for client debugging.

Syntax

➤ DUMP — *parameter* ➤

Parameters

n

Specifies the ID number of a specific extended trace point that is to be activated in the FTP code. The number is an integer in the range 1 - 99.

FSC

Activates all of the extended trace points in the file services code.

JES

Activates all of the extended trace points in the JES services code.

Restriction: This applies to the server only.

SOC

Activates all of the extended trace points in the network services code.

SQL

Activates all of the extended trace points in the SQL services code.

ALL

This parameter is used to set all of the trace points. It sets dump IDs 1 to 99.

USERID (*filter_name*)

This parameter is used to filter the extended trace for user IDs matching the *filter_name* pattern. If the user ID matches the filter at the time the client logs in, tracing options are set to the current value of the options. Otherwise, no extended tracing options are set. The client might use the SITE command to set options after login if the initial ones are not appropriate. An example for the USERID filter is:

```
DUMP USERID(USER33)
```

which activates the dumpID trace for a user if the user ID is USER33.

Restriction: This applies to the server only.

IPADDR (*filter/subnet mask*)

This parameter is used to filter the extended trace for IP addresses matching the filter pattern. If the IP address matches the filter at the time the client connects, extended tracing options are set to the current value of the options. Otherwise, no extended tracing options are set. The client might use the

SITE command to set options after connect if the initial ones are not appropriate. Examples of the IPADDR filter are:

```
DUMP IPADDR(9.67.113.57)
DUMP IPADDR(FEDC:BA98:7654:3210:FEDC:BA98:7654:3210)
```

The first example activates the extended traces for a client whose IP address is 9.67.113.57; the second activates the extended traces for a client whose IP address is FEDC:BA98:7654:3210:FEDC:BA98:7654:3210.

If the filter is an IPv4 address, submasking can be indicated by using a slash followed by a dotted decimal submask. For example, 192.48.32/255.255.255.0 allows addresses from 192.48.32.00 to 192.48.32.255. If the filter is an IPv6 address, network prefixing can be indicated by using a slash followed by a network prefix. For example, use FEDC:BA98::0/32 to indicate the prefix: FEDCBA98.

Restriction: This applies to the server only.

DUMPONSITE (FTP server) statement

Use the DUMPONSITE statement to specify whether the FTP server accepts a SITE DUMP command to change the extended tracing options for the FTP session.

Syntax

Parameters

TRUE

The FTP server allows an FTP client to change the extended trace options with a SITE DUMP command.

FALSE

The FTP server does not allow an FTP client to change the extended trace options with a SITE DUMP command. This is the default.

Related topics

- [“DUMP \(FTP client and server\) statement” on page 677](#)
- See [z/OS Communications Server: IP User's Guide and Commands](#) for more information about the [SITE subcommand](#).

EATTR (FTP client and server) statement

Use the EATTR statement to specify whether new data sets can have extended attributes and whether the data sets can reside in the EAS of an EAV. You can also use the SIte and LOCSite subcommands to set this keyword.

Server

This setting applies when creating data sets on the server's system.

Client

This setting applies when creating data sets on the client's system.

Syntax

Parameters

NO

The new data set cannot reside in the EAS, and its VTOC entry cannot have extended attributes.

OPT

The new data set can reside in the EAS, and its VTOC entry can have extended attributes if the volume supports them.

SYSTEM

The new data set will use the SMS data class EATTR value. If no SMS data class is defined, or if the data class contains no EATTR specification, the data set will be allocated with the system default. This is the default.

Examples

To allow new data sets to have extended attributes if the volume supports them, and to allow new data sets to reside in the EAS, code the following statement in FTP.DATA:

```
EATTR  OPT
```

Related topics:

- [“SPACETYPE \(FTP client and server\) statement” on page 765](#)
- [“VOLUME \(FTP client and server\) statement” on page 788](#)

EMAILADDRCHECK (FTP server) statement

Use the EMAILADDRCHECK statement to control the extent to which the FTP server validates e-mail addresses entered by FTP clients while logging in to the FTP server.

Restriction: This statement is meaningful only when ANONYMOUSLEVEL is 3 or greater.

Syntax

Parameters

NO

The FTP server does not validate the e-mail address entered by the FTP client. Whatever the user entered is accepted and the user can log in. This is the default.

FAIL

The FTP server verifies that the e-mail address entered by the FTP client is a valid e-mail address before allowing the user to log in. The FTP server rejects the login if the e-mail address is not valid.

WARNING

The FTP server inspects the e-mail address entered by the FTP client. Any value the client enters is accepted as valid; however, the FTP server returns a warning reply to the client if the e-mail address is not plausible. In either case, the FTP server allows the FTP client to log in.

Examples

To ensure that only anonymous users entering valid e-mail addresses are allowed successful login, set the following parameter in FTP.DATA:

```
EMAILADDRCHECK FAIL; Requires anonymous users to enter a valid email address.
```

Usage notes

The FTP server prompts anonymous users for an e-mail address instead of a password when ANONYMOUSLEVEL is 3.

Related topics

- [“ANONYMOUS \(FTP server\) statement” on page 630](#)
- [“ANONYMOUSLEVEL \(FTP server\) statement” on page 638](#)
- [“The FTCHKPWD user exit” on page 596](#)

ENCODING (FTP client and server) statement

Use the ENCODING statement in the server and client FTP.DATA to indicate the type of data encoding on the network. You can also use the SItE and LOCStE subcommands to set this keyword.

Server

Specifies to the server whether to use single or double-byte code pages.

Client

Specifies to the client whether to use single or double-byte code pages.

Syntax

Parameters

SBCS

Specifies single byte encoding. Code pages are specified by way of the SBDATACONN statement. This is the default value.

MBCS

Specifies multibyte encoding. Code pages are specified by way of the MBDATACONN statement.

Rule: The data transfer Type must be ASCII to enable multibyte translation when ENCODING=MBCS is set.

Tip: The type is always ASCII when the client initially logs into the server.

Server

- The data transfer Type remains ASCII until the server receives a **Type** command from the client
- You can send a STAT command to the server to verify the Type setting by issuing the **stat** subcommand from the z/OS FTP client, or by issuing a QUOTE STAT command from any FTP client.

Client

- Certain subcommands, such as TYPE, BIG5, and others, change the data transfer Type.
- You can use the LOCSTAT subcommand to verify the Type setting.
- Use the TYPE subcommand to restore Type to ASCII

Examples

To indicate that data encoding was specified using MBDATACONN statement, use the following code:

```
ENCODING MBCS
```

Related topics

- [“MBDATACONN \(FTP client and server\) statement” on page 705](#)
- [“MBSENDEOL statement \(FTP client and server\) statement” on page 707](#)
- [“SBDATACONN \(FTP client and server\) statement” on page 731](#)
- [“SBSSENDEOL statement \(FTP client and server\) statement” on page 732](#)

EPSV4 (FTP client) statement

Use the EPSV4 statement to direct the FTP client to use EPSV and EPRT commands on IPv4 sessions. The locsite subcommand is also available to set this parameter.

Syntax

Parameters

FALSE

Prevents the client from using EPRT and EPSV commands on IPv4 sessions. This is the default.

TRUE

Directs the client to use EPRT and EPSV commands on IPv4 sessions.

Usage notes

EPRT and EPSV commands are described in RFC 2428. If the server rejects an EPRT or EPSV command during the session, the client stops sending EPRT and EPSV to that server regardless of how you have set EPSV4.

Guideline: If your client has trouble establishing a data connection on an IPv4 security protected, encrypted session through an NAT firewall, coding EPSV4 TRUE in the client's FTP.DATA can help.

Restrictions:

- The FTP server ignores this statement.
- Socksified sessions use PASV or PORT commands to establish data connections, as specified by the FWFRIENDLY setting. When EPSV4 is TRUE, the client attempts EPSV but never EPRT to establish a socksified data connection.
- Some FTP servers support EPRT and EPSV commands, but do not reply as described in RFC 2428. If the FTP server reply to EPSV or EPRT does not conform to RFC 2428, the client reacts as if the server has rejected the command.
- RFC 2428 stipulates EPSV is the preferred command to establish data connections. Therefore, when EPSV4 is TRUE, the client tries EPSV regardless of how you have set FWFRIENDLY. The client uses EPRT only to set up a data connection for proxy transfer.

Examples

To direct the client to use EPSV and EPRT commands on IPv4 FTP sessions, use the following code:

```
EPSV4 TRUE
```

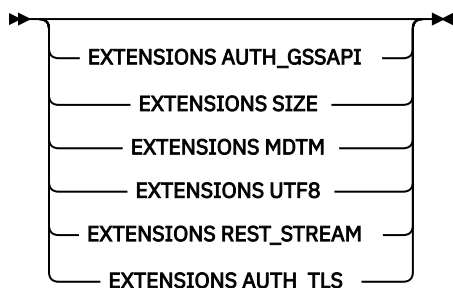

Related topics

- [“FWFRIENDLY \(FTP client\) statement” on page 689](#)
- [“PASSIVEIGNOREADDR \(FTP client\) statement” on page 714](#)

EXTENSIONS (FTP client and server) statement

Use the EXTENSIONS statement to enable FTP to support FTP extensions not described in RFC 959.

Syntax

Parameters

AUTH_GSSAPI

Specifies that GSSAPI authentication is supported. The server supports receiving the AUTH command with GSSAPI. AUTH_GSSAPI is supported for IPv4 connections only.

Restriction: This parameter applies to the server only.

SIZE

Enables the FTP Server to respond to the SIZE command. SIZE is supported for z/OS UNIX files only when the data transfer type is image, ASCII, or EBCDIC, the structure is file, and the data transfer mode is stream. If an FTP client requests MDTM or SIZE information for an MVS data set, or for any other unsupported file, the server returns an FTP reply code and error message instead of the requested information.

Restriction: This parameter applies to the server only.

MDTM

Enables the FTP Server to respond to the MDTM command. MDTM is supported for z/OS UNIX files only.

Restriction: This parameter applies to the server only.

UTF8

Enables the FTP server to respond to the LANG command, and to use UTF-8 encoding of pathnames on the control connection. The server ignores configuration options that direct it to use a specific code page on the control connection, as well as SITE commands that specify a specific code page on the control connection. The server initializes the control connection to use 7-bit ASCII until a LANG command from the client directs it to use UTF-8 encoding of pathnames. The only language supported by the server is United States English.

When the client has EXTENSIONS UTF8 encoded in FTP.DATA, the client has the language and subcommands available. Configuration options that direct the client to use a specific code page on the control connection, as well as LOCSITE commands that specify a specific code page on the control connection, are ignored. Initially the client uses 7-bit ASCII on the control connection. During client login, the client queries the server to determine whether it supports UTF-8 encoding. If so, it uses UTF-8 encoding of pathnames on the control connection.

Restriction: This parameter applies to both the client and the server.

REST_STREAM

Enables the FTP server to restart stream mode file transfers. The server ignores EXTENSIONS REST_STREAM unless EXTENSIONS SIZE is also coded, because stream restarts rely on the SIZE command.

Restriction: This parameter applies to the server only.

AUTH_TLS

Specifies that TLS authentication is supported. The server supports receiving the AUTH command with the following values:

- TLS: When the server successfully processes the AUTH TLS command and completes the handshake with the FTP client, the control connection is protected by TLS.
- TLS-C: When the server successfully processes the AUTH TLS-C command and completes the handshake with the FTP client, the control connection is protected by TLS.
- TLS-P: When the server successfully processes the AUTH TLS-P command and completes the handshake with the FTP client, the control connection is protected by TLS. The server also implicitly protects all data connections.
- SSL: When the server successfully processes the AUTH SSL command and completes the handshake with the FTP client, the control connection is protected by TLS. The server also implicitly protects all data connections.

Restriction: This parameter applies to the server only.

Results:

- This parameter also enables server support for the PROT and PBSZ commands.
- Server support for TLS-secured sessions is affected by the TLSRFCLEVEL setting.

Examples

```
EXTENSIONS SIZE
```

```
EXTENSIONS MDTM
```

Usage notes

- The EXTENSIONS statement has no default value.
- If you do not include an EXTENSIONS statement in FTP.DATA, no extensions to RFC 959 are recognized.
- Unlike other FTP.DATA statements, EXTENSIONS statements are cumulative. If you include an EXTENSIONS SIZE statement in FTP.DATA and also an EXTENSIONS MDTM statement, the FTP server receives both the SIZE and MDTM commands.
- The only way to disable an EXTENSIONS statement is to remove that statement from FTP.DATA. You can remove a statement by changing it to a comment or by deleting the statement.
- The SIZE and MDTM commands are not part of RFC 959. They are proposed commands described by an Internet-Draft published by the IETF (Internet Engineering Task Force). Because these commands are not part of an RFC, the FTP server supports them only if FTP.DATA includes EXTENSIONS statements to explicitly enable them.

Related topics

- [“TLSRFCLEVEL \(FTP client and server\) statement” on page 774](#)
- See [z/OS Communications Server: IP Configuration Guide](#) for more information about [SSL/TLS security](#), [key rings](#), and [certificates](#).

FIFOIOTIME (FTP client and server) statement

Use the FIFOIOTIME statement to set a timeout for reading and writing to a UNIX named pipe. This timeout is the maximum length of time FTP waits for I/O to a UNIX named pipe to complete. You can use the SIte and LOCSite subcommands to set this value.

Server

Specifies how long the server waits for reads from and writes to a UNIX named pipe to complete.

When you are retrieving data from a named pipe in the FTP server file system, this statement specifies the length of time the server waits for reads from the named pipe to complete.

When you are storing data into a named pipe in the FTP server file system, this statement specifies the length of time the server waits for writes to the named pipe to complete.

If no data is written to or read from the named pipe in the FIFOIOTIME interval, the FTP server fails the file transfer.

Tip: Setting FIFOIOTIME to a small value interrupts the server needlessly. This can have a deleterious impact on FTP performance.

Client

Specifies the length of time that the client waits for reads from and writes to a UNIX named pipe to complete.

When you are sending a file from a named pipe in the FTP client file system to the FTP server, this statement specifies the length of time that the client waits for reads from the named pipe to complete.

When you are getting a file from the FTP server and storing it into a named pipe in the FTP client server file system, this statement specifies the length of time the client waits for writes to the named pipe to complete.

If no data is written to or read from the named pipe in the FIFOIOTIME interval, the FTP client fails the file transfer.

Syntax

Parameters

seconds

The number of seconds in the range 1 - 86 400. The default is 20.

Examples

Use the following code to set the timer to 60 seconds:

```
FIFOIOTIME 60
```

Related topics

- [“FIFOOPEN TIME \(FTP client and server\) statement” on page 685](#)
- [“UNIXFILETYPE \(FTP client and server\) statement” on page 784](#)

FIFOOPEN TIME (FTP client and server) statement

Use the FIFOOPEN TIME statement to define the length of time that FTP waits after attempting to open UNIX named pipe before reporting an error. You can use the SIte and LOCSite subcommands to set this value.

Server

This setting specifies the length of time that the server waits for an open of a UNIX named pipe to complete.

Client

This setting specifies the length of time that the client waits for an open of a UNIX named pipe to complete.

Syntax

Parameters

seconds

The number of seconds that FTP waits for an open of a UNIX named pipe to complete. Valid values are in the range 1 - 86 400. The default is 60.

Examples

Use the following code to set the timer to 600 seconds:

```
FIFOOPEN TIME 600
```

Related topics

- [“FIFOIOTIME \(FTP client and server\) statement” on page 684](#)
- [“UNIXFILETYPE \(FTP client and server\) statement” on page 784](#)

FILETYPE (FTP client and server) statement

Use the FILETYPE statement to specify the method of operation for FTP.

Syntax

Parameters

JES

Remote job submission.

Restriction: This parameter applies to the server only.

SEQ

MVS data sets or z/OS UNIX files. SEQ is the method of operation supported by all FTP platforms. This is the default.

SQL

SQL query function. SQL method affects the RETR command at the server and the PUT subcommand at the client.

Examples

Set the operational method to SQL:

```
Filetype SQL
```

Usage notes

- SQL pertains to z/OS platform only. For more information about the effects on command processing when FILETYPE is SQL, see [z/OS Communications Server: IP User's Guide and Commands](#).
- When the SQL method is specified for the server, it affects the RETR command only. When the SQL method is specified for the client, it affects the STOR command only.
- JES pertains to the z/OS platform only and is valid only in the FTP.DATA file for a server. For more information about the effects on command processing at the server when the server's FILETYPE is JES, see [z/OS Communications Server: IP User's Guide and Commands](#).
- JES method affects the STOR, LIST, RETR, and NLST commands.
- The SAF resource EZB.FTP.sysname.ftpd daemonname.ACCESS.JES can be used to control access to FTP JES mode. See [\(Optional\) Steps for controlling user access to FTP JES mode in z/OS Communications Server: IP Configuration Guide](#).

- [z/OS Communications Server: IP Configuration Guide](#) for information about JESINTERFACELEVEL

FTPKEEPALIVE (FTP client and server) statement

Use the FTPKEEPALIVE statement to define the control connection keepalive timer value in seconds. This sets a socket level keepalive timer for the control connection. This allows the keepalive mechanism to send a packet on the idle control connection every FTPKEEPALIVE seconds, and avoid the firewall timing out the control connection.

Server

Specifies how often the server sends a keepalive packet.

Client

Specifies how often the client sends a keepalive packet.

Syntax

Parameters

seconds

The number of seconds before a keepalive packet is sent out on the FTP control connection. The valid range is 0 (FTPKEEPALIVE not used) or 60 - 86 400. The default is 0.

Examples

Set the FTP keepalive timer to 60 seconds:

```
FTPKEEPALIVE 60
```

Usage notes

If you specify 0 seconds, the FTPKEEPALIVE timer is disabled and the only keepalive packets that flow on the control connection would be controlled by whatever interval for keepalive packets you have configured in the stack.

FTPLOGGING (FTP server) statement

Use the FTPLOGGING statement to indicate whether the FTP server should log FTP server activity. The following types of activities are logged:

- Connectivity
- Authentication
- Access
- Allocation
- Deallocation
- Data transfer
- JES job submission
- SQL query
- Abnormal end
- Confidence of success level assigned to each file transfer when CHKCONFIDENCE is coded

The activities are logged in the SYSLOGD file. Each logging entry has a message number.

FTPLOGGING controls logging for non-anonymous user.

Syntax

Parameters

TRUE

The FTP server should log FTP session activity.

Tip: If TRUE is used, a long delay in login processing might occur because the FTP server issues a DNS query to resolve the remote host IP address.

TRUENODNS

The FTP server should log FTP session activity, however the client hostname lookup done during connection initiation is disabled. Message EZYFS50I contains UNKNOWN for the host name.

FALSE

The FTP server should not log FTP session activity.

Examples

To request that the FTP server log session activity:

```
FTPLOGGING TRUE
```

Usage notes

- Each activity logging message has a message number within the range of EZYFS50 to EZYFS95.
- If FTPLOGGING is TRUE, connectivity, authentication, and access activity log entries are made for all sessions because the server does not know whether the login is anonymous or not.

Related topics

- [“CHKCONFIDENCE statement \(FTP client and server\) statement” on page 650](#)
- See [“ANONYMOUSFTPLOGGING \(FTP server\) statement” on page 635](#) to control logging for an anonymous user.

FWFRIENDLY (FTP client) statement

Use the FWFRIENDLY statement to specify how data connections are to be set up between the client and the server.

Syntax

Parameters

TRUE

Specifies that the FTP client is firewall-friendly. This means that data connections are set up from the FTP client to the FTP server.

FALSE

Specifies that the FTP client is not firewall-friendly. This means that data connections are set up from the FTP server to the FTP client. This is the default.

Examples

```
FWFRIENDLY TRUE ; FTP client is firewall-friendly
```

Usage notes

When the connection to the server is IPv6, data connections are set up from client to the server regardless of the FWFRIENDLY setting.

Related topics

- [“EPSV4 \(FTP client\) statement” on page 681](#)
- [“PASSIVEIGNOREADDR \(FTP client\) statement” on page 714](#)

HFSINFO (FTP server) statement

Use the HFSINFO statement to specify a file containing welcome messages specific to each FTP server directory visited by an FTP user. In contrast to FTP users that are logged in as anonymous users, this statement affects only known users.

Syntax

➤ HFSInfo — *file-mask* ➤

Parameters

file-mask

The file-mask is a z/OS UNIX file mask used to find a z/OS UNIX information file for known users. The file mask can contain wildcards or it can be a complete file name. When a user changes directories, a search is conducted with the specified mask. The contents of the first file found is returned to the FTP client and is displayed to the end user. If no file is found matching the specified mask, no information is displayed to the end user.

Restriction: Wildcards work only when an asterisk (*) is placed after a string of characters.

Examples

Use the following code to direct the FTP server to search each directory to which a named FTP client changes, for a file matching the pattern msg*. Each time a named FTP client changes directory, the FTP server searches the target directory for files matching the file-mask msg*. The contents of the first matching file in each directory is returned to the FTP client.

```
HFSINFO msg* ; Real user HFS info file-mask  
; login
```

Usage notes

The default value of HFSINFO is <null>, meaning no welcome messages are displayed.

Related topics

- [“BANNER \(FTP server\) statement” on page 646](#)
- [“LOGINMSG \(FTP server\) statement” on page 703](#)
- [“MVSINFO \(FTP server\) statement” on page 710](#)

INACTIVE (FTP Server) statement

Use the INACTIVE statement to set the inactivity timer to a specified number of seconds. Any control connection that is inactive for the amount of time specified on this statement is closed by the server.

Syntax

Parameters

seconds

The number of seconds to which the inactivity timer is set. The valid range is 0 - 86 400. The default is 300. A value of 0 indicates no inactivity time is enabled, and the connection does not time out.

Examples

Set the inactivity timer to 30 seconds:

```
INACTIVE 30
```

Usage notes

- This value has no effect on the data connections. To specify a timeout value for the data connection, use the INTERVAL parameter of the TCPCONFIG statement in PROFILE.TCPIP. See the FTP configuration process in [z/OS Communications Server: IP Configuration Guide](#) for details.
- Specifying an INACTIVE value of zero can result in idle sessions remaining open indefinitely, which consumes system resources in an unproductive way. Code a nonzero value for INACTIVE to ensure that idle, unproductive sessions eventually expire.

Related topics

- [“FTPKEEPALIVE \(FTP client and server\) statement” on page 687](#)

INACTTIME (FTP client) statement

Use the INACTTIME statement to specify the amount of time the FTP client waits for an expected response from the server, on either the control or the data connection, before closing the session. Data transfer times that exceed this value does not cause session termination unless the time between data packet arrivals exceeds this value.

Syntax

Parameters

seconds

The number of seconds to which the timer is set. The valid range is 0 (INACTTIME not used) or 15-86400. The default is 120 seconds.

Examples

```
INACTTIME 160 ; wait 160 seconds
```

Usage notes

None

Related topics

See the FTP command and FTP environment information in [z/OS Communications Server: IP User's Guide and Commands](#).

ISPFSTATS (FTP client and server) statement

Use the ISPFSTATS statement to allow FTP to create and maintain statistics for partitioned data set members. You can also use the SITE and LOCSITE subcommands to set this keyword.

Server

This setting applies when creating or updating data sets on the server's system.

Client

This setting applies when creating or updating data sets on the client's system.

Syntax

Parameters

FALSE

FTP does not create statistics if the file does not already exist or does exist but does not have statistics. If the file already exists and contains statistics, FTP updates the statistics and sends the reply indicating the behavior.

TRUE

FTP creates or updates the statistics.

Examples

FTP creates the statistics:

```
ISPFSTATS TRUE
```

Usage notes

- The ISPFSTATS statement is ignored for sequential data sets; it applies to PDS and PDSE data sets. The record format must be either variable or fixed, and the record length must be less than 256.

- Transferring PDS member to PDS member in block mode or in compress mode differs in behavior from transferring in stream mode. If the user wants to preserve the statistics of the PDS member that already has statistics, and have the same statistics copied over to targeted PDS member, transferring in block mode or in compress mode is preferred.

JESENTRYLIMIT (FTP server) statement

Use the JESENTRYLIMIT statement to specify the number of entries that can be displayed concurrently through a LIST or NLST command when FILETYPE=JES and JESINTERFACELEVEL=2. You can also use the SITE command to set this keyword.

Syntax

Parameters

value

A numeral in the range of 1 - 1 024.

Examples

The following example illustrates a JESENTRYLIMIT of 10:

```
dir
EZA1701I >>> PORT 127,0,0,1,4,10
200 Port request OK.
EZA1701I >>> LIST
125 List started OK for JESJOBNAME=USER1*, JESSTATUS=ALL and JESOWNER=USER1
EZA2284I JOBNAME JOBID OWNER STATUS CLASS
EZA2284I USER1 TSU00025 USER1 OUTPUT TSU ABEND=222 3 spool files
EZA2284I USER1A JOB00209 USER1 OUTPUT A ABEND=806 3 spool files
EZA2284I USER1 JOB00201 USER1 OUTPUT A RC=0000 5 spool files
EZA2284I USER1J JOB00208 USER1 OUTPUT A (JCL error) 3 spool files
EZA2284I USER1 JOB00193 USER1 OUTPUT A RC=0000 5 spool files
EZA2284I USER1A JOB00200 USER1 OUTPUT A ABEND=806 3 spool files
EZA2284I USER1 JOB00179 USER1 OUTPUT A RC=0000 5 spool files
EZA2284I USER1 JOB00166 USER1 OUTPUT A RC=0000 5 spool files
EZA2284I USER1J JOB00199 USER1 OUTPUT A (JCL error) 3 spool files
EZA2284I USER1A JOB00187 USER1 OUTPUT A ABEND=806 3 spool files
250-JESENTRYLIMIT of 10 reached. Additional entries not displayed
250 List completed successfully.
EZA1460I Command:
```

Usage notes

- If JESENTRYLIMIT is not specified in FTP.DATA, the default is 200.
- JESENTRYLIMIT is valid only when JESINTERFACELEVEL is set to 2.

Related topics

- [“FILETYPE \(FTP client and server\) statement” on page 686](#)
- [“JESGETBYDSN \(FTP server\) statement” on page 693](#)
- [“JESINTERFACELEVEL \(FTP server\) statement” on page 694](#)

JESGETBYDSN (FTP server) statement

Use the JESGETBYDSN statement to specify how to use the foreign file name when retrieving a file with a value of FILETYPE=JES.

When the JESGETBYDSN statement value FALSE is coded or set to the default value, the foreign file specified when retrieving a file with FILETYPE=JES is read from the MVS system, submitted to JES as a batch job, and its output is retrieved to the client.

When the JESGETBYDSN statement value TRUE is coded, the foreign file specified when retrieving a file with FILETYPE=JES is read as a JES spool file data set name, and its output retrieved to the client. The JES spool file data set name is the same format as an MVS data set name, but it is a case-sensitive JES data set name. The JES data set name for a job can be found using SDSF on the Job Data Set panel (JDS). See [z/OS SDSF Operation and Customization](#) for more information about JES data set names.

Syntax

Parameters

FALSE

Specifies that the foreign file specified when retrieving a file with FILETYPE=JES is read from the MVS system, submitted to JES as a batch job, and its output is retrieved to the client. This is the default setting.

TRUE

Specifies that the foreign file specified when retrieving a file with FILETYPE=JES is read as a JES spool file data set name and its output is retrieved to the client.

Examples

The following example illustrates a JESGETBYDSN of FALSE:

```
JESGETBYDSN FALSE
```

Rule: The JESGETBYDSN statement only has meaning when FILETYPE=JES is specified and when JESINTERFACELEVEL 2 is coded in the FTP server's FTP.DATA file.

Related topics

- [“ANONYMOUSFILETYPEJES \(FTP server\) statement” on page 633](#)
- [“FILETYPE \(FTP client and server\) statement” on page 686](#)
- [“JESENTRYLIMIT \(FTP server\) statement” on page 693](#)
- [“JESINTERFACELEVEL \(FTP server\) statement” on page 694](#)
- [“JESLRECL \(FTP server\) statement” on page 696](#)
- [“JESRECFM \(FTP server\) statement” on page 697](#)

JESINTERFACELEVEL (FTP server) statement

Use the JESINTERFACELEVEL statement to specify the FTP-to-JES interface to be used by the installation. With JESINTERFACELEVEL 1, FTP users can submit jobs to JES, retrieve held output matching their logged-in user ID plus one character, and delete held jobs matching their logged-in user ID plus one character.

With JESINTERFACELEVEL 2, FTP users can retrieve and delete any job in the system for which they have the security access facility (SAF) resource class JESSPOOL access. Their ability to submit jobs is governed by the JESJOBS class SAF resource. JESINTERFACELEVEL 2 should only be specified if security measures are in place to ensure process access to JES output. For more information about SDSF security see [z/OS SDSF Operation and Customization](#).

JESINTERFACELEVEL 2 uses the SAPI interface to JES, so READ authority to the JESSPOOL resource is required to list job status or retrieve job output. See [z/OS JES2 Initialization and Tuning Guide](#) for more information about JES security. See [z/OS MVS Using the Subsystem Interface](#) for more information about the SAPI interface.

The SAF controls used for JESINTERFACELEVEL 2 are essentially a subset of those used by SDSF. Therefore, if an installation has customized SAF facilities for SDSF, it is configured for FTP JES JESINTERFACELEVEL 2.

Note: You are not required to have SDSF to use JESINTERFACELEVEL 2. If you do not use SDSF, you need to create SAF profiles. Both SDSF and JESINTERFACELEVEL 2 use the same SAF profile names.

JESSPOOL defines resource names as [nodeid].[userid].[jobname].[dsid].[dsname]. An FTP user can delete job output if it has ALTER access to the resource that matches its node ID, user ID, and job name (generics can be used). If the FTP client has READ access to the resource, it can list or retrieve the job output. FTP uses three filters to control the display of jobs. These filters employ SDSF resources. The first filter, JESSTATUS, can be changed by an FTP client by way of the SITE command to filter jobs in INPUT, ACTIVE, or OUTPUT state. The second filter, JESOWNER, has the value of the logged-in user ID by default. The third filter, JESJOBNAME, has the value of the logged-in user ID plus an asterisk (*) by default. JESSTATUS uses the SDSF resources ISFCMD.DSP.INPUT.jesx, ISFCMD.DSP.ACTIVE.jesx, and ISFCMD.DSP.OUTPUT.jesx. At login time, the default value for JESSTATUS is set to ALL if READ access is allowed to all three classes. Otherwise, the server attempts to set the value to OUTPUT, ACTIVE, and then INPUT if the appropriate READ access is allowed. If no READ access is allowed to any of the classes, JESSTATUS is set to OUTPUT but JESOWNER and JESJOBNAME cannot be changed from their default values. In this way, SAF controls can be put in place to limit FTP users to whatever status of jobs an installation requires.

Authority to change JESOWNER is obtained by way of READ access to RACF profile ISFCMD.FILTER.OWNER. Authority to change JESJOBNAME is obtained by way of READ access to RACF profile ISFCMD.FILTER. An FTP client with READ access to ISFCMD.FILTER.OWNER is allowed to change the JESOWNER parameter by way of the SITE command. An FTP client with READ access to ISFCMD.FILTER.PREFIX is allowed to change the JESJOBNAME parameter by way of the SITE command.

Syntax

Parameters

- 1 Specifies that FTP users can submit jobs to JES, retrieve held output matching their logged-in user ID plus one character, and delete held jobs matching their logged-in user ID plus one character. This is the default.
- 2 Specifies that FTP users can retrieve and delete any job in the system for which they have the security access facility (SAF) resource class JESSPOOL access. Their ability to submit jobs is governed by the JESJOBS class SAF resource.

Guideline: JESINTERFACELEVEL 2 should only be specified if security measures are in place to ensure process access to JES output.

Examples

The following code is an example of commands used to allow all FTP users other than USER1 the ability to change JESOWNER. USER1 is only allowed the default JESOWNER value and not allowed to change JESOWNER by way of the SITE command.

```
JESOWNER: setropts classact(SDSF) refresh
rdefine SDSF (isfcmd.filter.owner) uacc(read)
permit isfcmd.filter.owner access(none) class(SDSF) id(user1)
setropts classact(SDSF) refresh
```

Requirement: If JESINTERFACELEVEL 2 is specified, an installation must ensure that security measures are in place to control FTP client access to jobs.

Result: This statement applies only when FILETYPE JES is active.

Related topics

JESLRECL (FTP server) statement

Use the JESLRECL statement to specify the record length of the jobs being submitted. You can also use the SITE command to set this keyword.

Syntax

Parameters

length

The record length of the job being submitted. The valid range is 1 - 254. The default is 80. If you specify *length* as *, FTP uses the length value from the LRECL statement.

Examples

Explicitly set the logical record length for JES jobs to 80:

```
JESLRECL 80
```

Usage notes

- If JESLRECL * is specified, the LRECL value is used for jobs being submitted.
- This statement applies only when FILETYPE JES is active.

Related topics

- [“FILETYPE \(FTP client and server\) statement” on page 686](#)
- [“JESGETBYDSN \(FTP server\) statement” on page 693](#)
- [“LRECL \(FTP client and server\) statement” on page 704](#)

JESPUTGETTO (FTP server) statement

Use the JESPUTGETTO statement to specify the number of seconds of the JES PutGet timeout.

The JES PutGet timeout is used when the FTP client performs a GET with a source and a target name. The source job is submitted to JES. The server waits until the JES PutGet timeout expires or until the job completes. If the job completes, it stores the output in the target name file. If the job does not complete, the FTP client displays the server reply to the end user.

Syntax

Parameters

seconds

The number of seconds of the JES PutGet timeout. The valid range is 0 - 86 400 (24 hours). The default is 600 (10 minutes).

Examples

Set the number of seconds of the JES PutGet timeout to 300:

```
JESPUTGETTO 300
```

Usage notes

- The JESPUTGETTO value should be high enough for most jobs to complete within the specified time but not be so high (for example, 86400) that end users wait excessive amounts of time for job completion.
- Use 86400 if the JES PutGet is done *only* from batch jobs that must wait for the job to complete and end user wait time is not an issue.
- This statement applies only when FILETYPE JES is active.

Related topics

- [“ANONYMOUSFILETYPEJES \(FTP server\) statement” on page 633](#)
- [“FILETYPE \(FTP client and server\) statement” on page 686](#)
- [“JESENTRYLIMIT \(FTP server\) statement” on page 693](#)
- [“JESGETBYDSN \(FTP server\) statement” on page 693](#)
- [“JESINTERFACELEVEL \(FTP server\) statement” on page 694](#)
- [“JESLRECL \(FTP server\) statement” on page 696](#)
- [“JESRECFM \(FTP server\) statement” on page 697](#)

JESRECFM (FTP server) statement

Use the JESRECFM statement to specify the record format of jobs being submitted. This is the record format used during dynamic allocation of the internal reader when submitting jobs to JES. You can also use the SITE command to set this keyword.

Syntax

Parameters

F

Fixed record length. This is the default.

V

Variable record format.

*

Uses the record format specified on the RECFM statement.

Examples

Use fixed record format:

```
JESRECFM F
```

Usage notes

- Use only the value F when running on JES2 systems.
- If FTP cannot allocate the internal reader, the FTP client receives a 550 JES internal reader allocation failed reply when submitting jobs to JES.
- This statement applies only when FILETYPE JES is active.

Related topics

- [“FILETYPE \(FTP client and server\) statement” on page 686](#)
- [“JESGETBYDSN \(FTP server\) statement” on page 693](#)
- [“RECFM \(FTP client and server\) statement” on page 723](#)

KEYRING (FTP client) statement

Use the KEYRING statement to define the key ring that contains the certificate to be used during the TLS handshake. Specifies the key ring database on the client's system.

Note: This parameter is only meaningful if TLSMECHANISM FTP is specified. If TLSMECHANISM ATTLS is specified, then the keyring must be configured in the AT-TLS policy.

Syntax

Parameters

keyringname

The name of the keyring. If the name begins with a slash (/), it is the name of the key database HFS file. Otherwise, it is an SAF keyring created by using the RACF ADDRING function.

userid/keyringname

Allows multiple FTP users to share one key ring owned by another user. The *keyringname* value is the SAF key ring created by using the RACF ADDRING function. The *userid* value must be the user that owns the key ring.

Restrictions:

- For a SAF keyring, all users must be given access to the keyring. If keyring access is protected using the RDATA LIB class, the users must have READ access to *KeyRingOwner.KeyRingName.LST* resource. For example, for a SAF key ring defined as RING01 that is owned by the user ID SHAREID, the users would need to be given READ access to the SHAREID.RING01.LST resource in the RDATA LIB class.
- If keyring access is protected using the FACILITY class, the users must have UPDATE access to the IRR.DIGTCERT.LISTRING resource in the FACILITY class when using an SAF key ring owned by another user.

Examples

```
KEYRING /u/user33/keyring/key.kdb
```

```
KEYRING user33/ftpring
```

```
KEYRING ftpring
```

Guideline: For an SAF keyring, if the *userid* is omitted, the user ID specified on the FTP USER command by the client is used.

Usage notes

- KEYRING is required if TLS is used as a security mechanism.
- The SECURE_MECHANISM TLS and TLSMECHANISM FTP statements must be coded for this statement to be used by an FTP client.

Related topics

- [“SECURE_MECHANISM \(FTP client\) statement” on page 744](#)
- [“TLSMECHANISM \(FTP client and server\) statement” on page 772](#)
- See [z/OS Communications Server: IP Configuration Guide](#) for more information about [SSL/TLS security](#), [key rings](#), and [certificates](#) and [SSL/TLS](#).

LISTLEVEL (FTP server) statement

Use the LISTLEVEL statement to specify the format of the LIST reply.

Syntax

Parameters

0

Specifies that PDS, PDSE and z/OS UNIX data sets are displayed with a DSORG value of PO.

1

Specifies that PDS data sets are displayed with a DSORG value of PO, PDSE data sets are displayed with a DSORG value of PO-E, and z/OS UNIX data sets are displayed with a DSORG value of z/OS UNIX file system.

Examples

Set the LISTLEVEL parameter value to 1 when you want to distinguish PDS, PDSE and z/OS UNIX data sets in the LIST reply:

```
LISTLEVEL 1
```

LISTSUBDIR (FTP client and server) statement

Use the LISTSUBDIR statement to indicate whether wildcard searches should span subdirectories or apply only to the current working directory. You can use the SITE and LOCSITE subcommands to reset this keyword.

Server

This setting applies when processing the NLST command. The z/OS FTP client sends an NLST command to the server when issuing any of the following subcommands:

- LS *
- MDELETE *
- MGET *

Client

This setting applies when the z/OS FTP client issues an MPUT * subcommand.

This statement only applies when the asterisk (*) wildcard symbol is used in the filename parameter and the GLOB subcommand is set to expand metacharacters in file names. The ls, mdelete, mget and mput subcommands search only the subdirectories of the current path. They do not search multiple depths of subdirectories.

Syntax

Parameters

TRUE

This is the default. Indicates the files in the subdirectories of the current working directory are listed when processing wildcard searches.

FALSE

Indicates that the files in the subdirectories of the current working directory are not listed when processing wildcard searches.

Examples

Directory /u/user1/xx contains the following files and subdirectory:

```
areadme (file)
file_xx (file)
readme_xx (file)
ggg (subdirectory)
```

Directory /u/user1/xx/ggg contains the following files and subdirectory:

```
file_ggg (file)
zzz (subdirectory)
```

Directory /u/user1/xx/ggg/zzz contains the following files and subdirectory:

```
file_zzz (file)
rrr (subdirectory)
```

The following display shows these files and directories:

```
250 HFS directory /u/user1/xx is the current working directory
ftp> ls - l
200 Port request OK.
125 List started OK
total 40
-rwx----- 1          IBMUSER  0          48 Oct 29  21:14 areadme
-rwx----- 1          IBMUSER  0          10 Nov  1  16:02 file_xx
drwxrwxrwx  3          IBMUSER  0      8192 Nov  1  16:00 ggg
-rwx----- 1          IBMUSER  0          23 Oct 29  21:06 readme_xx
250 List completed successfully.
260 bytes received in 0.03 seconds (8.67 Kbytes/sec)
ftp> cd gg
260 HFS directory /u/user1/xx/ggg is the current working directory
ftp> ls - l
200 Port request OK.
125 List started OK
total 24
-rwx----- 1          IBMUSER  0          6 Oct 29  16:00 file_ggg
drwxr-x---  3          IBMUSER  0      8192 Nov  1  16:01 zzz
250 List completed successfully.
133 bytes received in 0.02 seconds (6.65 Kbytes/sec)
cd zzz
250 HFS directory /u/user1/xx/ggg/zzz is the current working directory
ftp> ls - l
200 Port request OK.
125 List started OK
total 24
-rwx----- 1          IBMUSER  0          4 Nov 29  16:00 file_zzz
drwxr-xr-x  3          IBMUSER  0      8192 Nov  1  16:01 rrr
250 List completed successfully.
133 bytes received in 0.01 seconds (13.30 Kbytes/sec)
```

If you have coded LISTSUBDIR FALSE in the server's FTP.DATA file or specified SITE NOLISTSUBDIR, the client sees the following display:

```
257 "/u/user1/xx" is the current working directory
ftp> ls *
200 Port request OK.
125 List started OK
areadme
file_xx
readme_xx
```

```
250 List completed successfully.  
29 bytes received in 0.02 seconds (1.45 Kbytes/sec)
```

If you have coded LISTSUBDIR TRUE in the server's FTP.DATA file or specified SITE LISTSUBDIR, the client sees the following display:

```
257 "/u/user1/xx" is the HFS working directory  
ftp> ls *  
200 Port request OK.  
125 List started OK  
areadme  
file_xx  
ggg/file_ggg  
readme_xx  
250 List completed successfully.  
42 bytes received in 0.04 seconds (1.05 Kbytes/sec)
```

When spanning subdirectories with the wildcard *, the file ggg/file_ggg is shown. However, the file ggg/file_zzz is not shown because the subdirectory span is only one level deep.

Restriction: The LISTSUBDIR statement applies to z/OS UNIX file operations only. MVS data set operations are not affected.

- locsite for the LISTSUBDIR option

LOGCLIENTERR (FTP client) statement

Use the LOGCLIENTERR statement to specify whether the FTP client should log client errors with message EZZ9830I.

Result: Message EZZ9830I is issued for any error that causes FTP to exit. If you have not configured FTP to exit on error by specifying the EXIT or EXIT=nn parameter on the FTP command, or by coding the CLIENTEXIT TRUE statement in FTP.DATA, the FTP client will issue message EZZ9830I on the first error that would have caused FTP to exit if you configured FTP to exit on error.

Syntax

Parameters

TRUE

Specifies that the FTP client should log message EZZ9830I when an FTP client subcommand fails.

FALSE

Specifies that the FTP client should not log message EZZ9830I when an FTP client subcommand fails. This is the default.

Examples

```
LOGCLIENTERR TRUE ; log client errors
```

Related topics

- [“CLIENTERRCODES \(FTP client\) statement” on page 657](#)
- [FTP client error logging in z/OS Communications Server: IP User's Guide and Commands](#)

LOGINMSG (FTP server) statement

Use the LOGINMSG statement to specify the file containing messages to be displayed to FTP users when they have successfully logged in. This statement affects only named FTP clients as opposed to FTP clients logged in as anonymous.

Syntax

►► LOGINMSG — *file-path* ►◄

Parameters

file-path

The fully qualified z/OS UNIX pathname or the fully qualified MVS data set name of the file whose contents are displayed whenever a user logs in to FTP.

Requirements:

- A z/OS UNIX pathname must start with a slash (/).
- An MVS data set must not start with a slash character.

Examples

Use the following statement if the FTP login message is kept in the file /etc/ftp.login:

```
LOGINMSG /etc/ftp.login  
; Welcome message for FTP users
```

Usage notes

- LOGINMSG does not apply to anonymous user logins. To provide this function to anonymous users, use the ANONYMOUSLOGINMSG statement.
- When a known FTP user successfully logs in, the FTP server searches for the file specified by file-path. The contents of the file are returned to the FTP user as 230-prefixed replies. If the file specified by file-path does not exist, no messages are returned to the FTP client and no login messages are displayed to the end user.

- [“MVSINFO \(FTP server\) statement” on page 710](#)

LRECL (FTP client and server) statement

Use the LRECL statement to specify the size of the logical records in a data set.

Server

This setting applies when creating files on the server's system. For example, with a PUT subcommand.

Client

This setting applies when creating files on the client's system. For example, with a GET subcommand.

Syntax

Parameters

length

The size of the records in a data set. The valid range is 0 - 32760 or x. The default is 256. x corresponds to a length of 32768. x does not correspond to the LRECL=X parameter of z/OS MVS JCL.

Examples

Set the logical record length to 128 bytes:

```
LRECL 128
```

Specify no value for LRECL to allow the LRECL of a model DCB data set or SMS dataclass to be used:

```
LRECL
```

Usage notes

- The record size attribute can be obtained from an SMS data class using the DATACLASS configuration statement, from a model data set using the DCBDSN configuration statement, or from the LRECL statement.
- Use LRECL without a size if you have:
 - Specified a DATACLASS statement and want to use the record size from the data class, or
 - Specified a DCBDSN statement and want to use the record size from the model data set.
- If you specify a DATACLASS, a DCBDSN, and LRECL without size, the value from the model data set is used.
- To override the record size attribute from the DATACLASS or DCBDSN settings:
 - Specify LRECL with a value other than 0, or
 - Do not specify the LRECL statement, and use the default.
- If you specify no value for *length*, FTP does not specify the size of the records in a data set.

Related topics

- See the information about storage management subsystem (SMS) in [z/OS Communications Server: IP Configuration Guide](#) for more information about specifying attributes when allocating new data sets.

MBDATACONN (FTP client and server) statement

Use the MBDATACONN statement to define the conversions between a file system code page and a network transfer code page during data transfer. This statement affects the conversion of double-byte character set (DBCS) and multibyte character set (MBCS) data and is used when the ENCODING MBCS statement is coded. You can also use the SIte and LOCSite subcommands to set this keyword and to set ENCODING to MBCS.

Server

Specifies the multibyte code pages used by the server.

Client

Specifies the multibyte code pages used by the client.

Syntax

➤ MBDATACONN — (file_system_codepage,network_transfer_codepage) ➤

Parameters

file_system_codepage

Specifies the name of the file system code page.

network_transfer_codepage

Specifies the network transfer code page.

Examples

To code MBDATACONN:

```
MBDATACONN      (IBM-1388,IBM-5488)
```

Usage notes

MBDATACONN is in effect only when ENCODING has a value of MBCS.

Table 46 on page 705 shows the supported code page pairs.

Table 46. Supported code page pairs		
Support for:	file_system_codepage	network_transfer_codepage
Chinese standard GB18030	IBM-1388 or UTF-8	IBM-5488
BIG5	IBM-937	IBM-950 or BIG5
EUCKANJI	IBM-930	IBM-eucJP
JIS78KJ (JISROMAN)	IBM-930	IBM-5053
JIS78KJ (ASCII)	IBM-939	IBM-5055
JIS83KJ (JISROMAN)	IBM-930	IBM-5052

Table 46. Supported code page pairs (continued)		
Support for:	file_system_codepage	network_transfer_codepage
JIS83KJ (ASCII)	IBM-939	IBM-5054
KSC5601	IBM-933	IBM-949
SCHINESE	IBM-935	IBM-1381
SJISKANJI	SJISKANJI IBM-930 or IBM-939	IBM-932 or IBM-eucJC
TCHINESE	IBM-937	IBM-948
UNICODE file transfer	UTF-8, UTF-16	UTF-8, UTF-16, UTF-16BE, UTF-16LE

Other code page pairs might be accepted when specified. However, the ones listed in [Table 46 on page 705](#) have been verified to produce the support that is listed in the table.

Related topics

- [“ENCODING \(FTP client and server\) statement” on page 680](#)
- [“MBSENDEOL statement \(FTP client and server\) statement” on page 707](#)
- [“MBREQUIRELASTEOL \(FTP client and server\) statement” on page 706](#)
- [“SBDATACONN \(FTP client and server\) statement” on page 731](#)
- [Table 22 on page 395](#)

MBREQUIRELASTEOL (FTP client and server) statement

Use the MBREQUIRELASTEOL statement to specify whether FTP requires the last record of incoming multibyte files to end with the FTP standard EOL sequence.

Server

This setting applies when the server is receiving a multibyte file from the client.

Client

This setting applies when the client is receiving a multibyte file from the server.

Syntax

Parameters

TRUE

FTP reports an error when a multibyte file is received from the network without an EOL sequence in the last record received and aborts the file transfer. The CONDDISP configuration option determines whether the file or data set is saved or deleted.

FALSE

FTP does not report an error when a multibyte file is received from the network without an EOL sequence in the last record received. The file or data set is stored.

Results:

- If MBREQUIRELASTEOL is set to FALSE, and you have coded CHKCONFIDENCE TRUE in FTP.DATA, the confidence level reported when a multibyte file is received from the network without an EOL sequence in the last record is High.
- If MBREQUIRELASTEOL is set to TRUE, and you have coded CHKCONFIDENCE TRUE in FTP.DATA, the confidence level reported when a multibyte file is received from the network without an EOL sequence in the last record is Low.

Examples

To enable the FTP server to receive multibyte files that are sent with no EOL sequence on the final record, code the following statement in the server's FTP.DATA:

```
MBREQUIRELASTEOL FALSE
```

Related topics

- [“ENCODING \(FTP client and server\) statement” on page 680](#)
- [“MBDATACONN \(FTP client and server\) statement” on page 705](#)

MBSSENDEOL statement (FTP client and server) statement

Use the MBSSENDEOL statement to tell the FTP client or server what end-of-line (EOL) sequence to use when ENCODING is MBCS, Type is ASCII, Mode is Stream, and file transfer is outbound. You can also use the SItE and LOCSItE subcommands to set this keyword.

Server

When ENCODING is MBCS, data Type is ASCII, Mode is Stream, and files are sent from the server, this statement instructs the server which EOL sequence to append to each line of text.

Client

When ENCODING is MBCS, data type is ASCII, Mode is Stream, and files are sent from the client, this statement instructs the client which EOL sequence to append to each line of text.

Syntax

Parameters

CRLF

When translating multi-byte data to ASCII, append a carriage return (x'0D') and line feed (x'0A') to each line of text. This is the default and the standard EOL sequence defined by RFC 959. The z/OS server and client can receive ASCII data in this format only.

CR

When translating multi-byte data to ASCII, append only a carriage return (x'0D') to each line of text.

LF

When translating multi-byte data to ASCII, append only a line feed (x'0A') to each line of text.

NONE

When translating multi-byte data to ASCII, append no EOL sequence.

Results:

- This statement applies only to the end-of-line sequence used on the data connection. The control connection end-of-line sequence is not affected.
- SBCS, DBCS, and UCS-2 translations are not affected by this setting. UTF-8 and UTF-16 translations are affected by this setting

Rule: The MBSSENDEOL setting CRLF is appropriate for most file transfers. Do not use an alternate MBSSENDEOL setting unless you have verified that the recipient FTP can handle the alternate value.

Client

Do not code an alternate MBSSENDEOL value if your server is a z/OS FTP server. The z/OS FTP server does not support alternate MBSSENDEOL values for inbound file transfer.

Server

Do not code an alternate MBSSENDEOL value if your client is a z/OS FTP client. The z/OS FTP client does not support alternate MBSSENDEOL values for inbound file transfer.

Examples

Use LF as the EOL sequence when ENCODING is MBCS, Type is ASCII, and data transfer is outbound. Code as follows:

```
MBSSENDEOL  LF
```

Related topics

- [“ENCODING \(FTP client and server\) statement” on page 680](#)
- [“MBDATACONN \(FTP client and server\) statement” on page 705](#)
- [“SBSSENDEOL statement \(FTP client and server\) statement” on page 732](#)

MGMTCLASS (FTP client and server) statement

Use the MGMTCLASS statement to specify the SMS management class to be assigned to newly allocated data sets.

Server

This setting applies when creating files on the server's system.

Client

This setting applies when creating files on the client's system.

One of the attributes obtained from the management class is the retention period setting. If you specify a management class, then the retention period is obtained from the management class. The value of the management class's retention period can be overridden.

- If a data class (DATACLASS) is specified, the retention period in the data class can override it.
- If a model data set (DCBDSN) is specified, its retention period overrides both the data class value and the management class value.
- If you specify a value for RETPD statement, the value you specify overrides any data class setting, model data set value and any management class setting.

However, regardless of where the retention period value is obtained, when attempting to override the value set in the management class, the actual resulting retention period setting depends on the retention period limit defined in the management class. A management class is defined with a retention limit value as well as a retention period. If you attempt to override the management class's retention period, the override value must be within the retention period limit defined in the management class. Otherwise, the retention period used is the management class's retention limit value.

Syntax

➤ MGMTCLASS — *class* ➤

Parameters

class

The SMS management class.

Examples

Set the SMS management class for new data sets to TCPMGMT:

```
MGMTCLASS TCPMGMT
```

Related topics

- [“DATACLASS \(FTP client and server\) statement” on page 661](#)
- See the information about storage management subsystem (SMS) in [z/OS Communications Server: IP Configuration Guide](#) for more information about specifying attributes when allocating new data sets.
- [“STORCLASS \(FTP client and server\) statement” on page 769](#)

MIGRATEVOL (FTP client and server) statement

Use the MIGRATEVOL statement to specify the volume ID for migrated data sets under the control of a storage management system other than HSM.

Server

This setting applies when accessing files on the server's system.

Client

This setting applies when accessing files on the client's system.

Syntax

➤ { MIGRATEVOL MIGRAT } ➤
MIGRATEVOL — *volume_id*

Parameters

volume_id

The volume ID for migrated data sets. The default volume ID is MIGRAT.

Examples

Set the volume ID for migrated data sets to MIGRIX:

```
MIGRATEVOL MIGRIX
```

Related topics

[“RETPD \(FTP client and server\) statement” on page 729](#)

MVSINFO (FTP server) statement

Use the MVSINFO statement to specify MVS data sets whose contents are displayed to the user when the user changes directories. The statement identifies a low-level qualifier (LLQ) that is appended to the current path whenever an FTP user changes directories to an MVS data set.

Syntax

➤ MVSINFO — *MVS-LLQ* ➤

Parameters

MVS-LLQ

The MVS-LLQ is the MVS low-level qualifier (LLQ) appended to the current MVS path whenever an FTP client changes directories to an MVS data set. If a data set matches the current path appended LLQ, the contents of the data set are returned to the FTP client and displayed to the end user.

Examples

To display a readme file the first time a user changes directory to high-level qualifiers, use the following statement. In this example, an MVS high-level qualifier of `productname` might have a readme file for each product, and any time a user changed directory to the `productname`, the readme file would be displayed.

```
MVSINFO README
```

Usage notes

MVSINFO does not apply to anonymous users. Use the ANONYMOUSMVSINFO statement to define the informational banner used for anonymous users.

Related topics

- [“ANONYMOUSHFSINFO \(FTP server\) statement” on page 637](#)
- [“ANONYMOUSMVSINFO \(FTP server\) statement” on page 642](#)
- [“BANNER \(FTP server\) statement” on page 646](#)
- [“HFSINFO \(FTP server\) statement” on page 690](#)
- [“LOGINMSG \(FTP server\) statement” on page 703](#)

MVSURLKEY (FTP server) statement

Use the MVSURLKEY statement to specify a token that users can enter as part of an FTP URL to encode an MVS data set name.

Syntax

➤ MVSURLKEY — *key* ➤

Parameters

key

An arbitrary token users can enter in an FTP URL to signify that an MVS data set follows. Although the FTP server accepts any value, avoid symbols FTP clients might interpret as special characters or meta characters. For example, the # character is acceptable to the FTP server, but some Web browsers use the # character as a special character.

Examples

Use the following example to permit users to enter MVSDS in an FTP URL in order to tell the FTP server an MVS data set name follows:

```
MVSURLKEY MVSDS  
; code this in FTP.DATA
```

Code the following as an FTP URL to indicate that 'USER1.PROCLIB(FTPD)' is an MVS data set, not a z/OS UNIX data set:

```
ftp://user1@mvs098.tcp.raleigh.ibm/MVSDS/'user1.proclib(ftp)' ;type=a
```

Usage notes

- The key specified for MVSURLKEY can be set to be the same key used for the Websphere server to designate FTP URL encodings.
- The FTP server accepts an arbitrary string. Avoid characters the FTP client might interpret as metacharacters or special characters.

MYOPENTIME (FTP client) statement

Use the MYOPENTIME statement to specify the amount of time the FTP client waits for a session to open before terminating the attempt and reporting an error.

Syntax

Parameters

seconds

The number of seconds to which the timer is set. The valid range is 0 (MYOPENTIME not used) or 15-86 400. The default is 60 seconds.

Examples

```
MYOPENTIME 60 ; wait 60 seconds
```

Related topics

See the FTP command and the FTP environment information in [z/OS Communications Server: IP User's Guide and Commands](#).

NETRCLEVEL (FTP client) statement

Use the NETRCLEVEL statement to specify how the FTP client searches the NETRC data set for FTP server hostnames. This statement applies only if you have defined a NETRC data set for the client to use.

Syntax

Parameters

1

The FTP client searches the NETRC data set for the hostname as it was entered by the user: IP address or DNS name. If the client is running in batch mode, the client looks for the hostname in the NETRC data set only if a NETRC DD card is part of the batch job. This is the way the FTP client processed server hostnames up to and including release 320. This is the default.

2

The FTP client searches the NETRC data set for the hostname as it was entered by the user if the user entered a DNS name, or an IP address that cannot be resolved to a DNS name. If the hostname is an IP address that resolves to a DNS name, the FTP client searches the NETRC data set for the DNS name. If the FTP client is running as a batch job and no NETRC DD card is included, the FTP client uses 'userid.NETRC' as the NETRC data set.

Examples

```
NETRCLEVEL 2 ; convert IP addresses
```

Usage notes

The FTP server hostname is the DNS name or IP address the user entered to log in to the FTP server. This statement applies only if the FTP client is using a NETRC data set or file.

Related topics

See [z/OS Communications Server: IP User's Guide and Commands](#) for information about how to use the NETRC data set during the login process.

NONSWAPD (FTP server) statement

Use the NONSWAPD statement to allow the FTP daemon address space to run with nonswappable memory.

Syntax

Parameters

False

Do not set daemon nonswappable. This is the default.

True

Set daemon nonswappable.

Examples

To request that the daemon address space be set nonswappable, code:

```
NONSWAPD TRUE
```

Usage notes

- The FTP daemon must have at least READ access to the FACILITY class resource BPX.STOR.SWAP to enable this option.
- If the call to set the address space nonswappable fails for any reason, the daemon uses swappable memory and continue.
- When an application makes an address space nonswappable, it might cause additional real storage in the system to be converted to preferred storage. Because preferred storage cannot be configured offline, using this option can reduce the installation's ability to reconfigure storage in the future. See [z/OS MVS Programming: Resource Recovery](#) for more information.

PASSIVEDATACONN (FTP server) statement

When the server receives a PASV or EPSV command, it opens a listening socket. Any entity can connect to the listening socket. Use the PASSIVEDATACONN statement to direct the server to verify the peer IP address of the data socket is the client's IP address.

Syntax

Parameters

UNRESTRICTED

The server accepts a passive data connection from any IP address. This is the default.

NOREDIRECT

The server verifies the peer address of the data socket is the client's IP address. If it is not, the server closes the data socket.

Guideline: The server cannot be the passive server in a three way (proxy) data transfer when NOREDIRECT is coded, because the server rejects an attempt by the active server to connect to its passive socket.

Examples

Use the following example to set the server to reject passive data connections with IP address different from the IP addresses of the control connections:

```
PASSIVEDATACONN NOREDIRECT
PASSIVEDATACONN N
```

PASSIVEDATAPORTS (FTP server) statement

Use the PASSIVEDATAPORTS statement to assign a range of port numbers for the FTP server to use as listening data socket ports.

Syntax

➤ PASSIVEDATAPORTS (low_port, high_port) ➤

Parameters

low_port

The lowest port number the FTP server is allowed to use when creating a listening data socket. The lowest number allowed for low_port is 1 024.

high_port

The highest port number the FTP server is allowed to use when creating a listening data socket. The highest number allowed for high_port is 65 535.

By default, the FTP server allows the stack to select a port number from its entire range of ephemeral ports for listening data sockets. PASSIVEDATAPORTS affects ports selected for the data connection only; the control connection ports are not affected. PASSIVEDATAPORTS is useful in conjunction with firewalls that restrict the range of port numbers allowed to FTP.

Guideline: Code a PORTRANGE AUTHPORT statement in PROFILE.TCPIP to reserve the ports you have specified with PASSIVEDATAPORTS. If you are using a sysplex DVIPA to distribute the FTP server workload with sysplex ports, code the same PORTRANGE AUTHPORT statement for each participating stack in the sysplex.

Restriction: If you have PORTRANGE statements in PROFILE.TCPIP that reserve ports for a different application, and those reserved ports intersect with the PASSIVEDATAPORTS ports, the FTP server is never able to obtain those ports.

Examples

To restrict the server's choice of ports for listening data sockets to ports from 50000 to 50099, code the following statement in FTP.DATA:

```
PASSIVEDATAPORTS (50000,50099)
```

To prevent other applications from consuming ports in the range 50 000 - 50 099, code the following statement in PROFILE.TCPIP:

```
PORTRANGE 50000 100 TCP AUTHPORT
```

PASSIVEIGNOREADDR (FTP client) statement

Use the PASSIVEIGNOREADDR statement to direct the FTP client to ignore the IP address returned from the server on the PASV reply on IPv4 sessions. You can also use the subcommand to set this parameter.

Restrictions:

- The FTP server ignores this statement.

- When EPSV4 and PASSIVEIGNOREADDR are TRUE, the client tries the EPSV command first. If the EPSV command does not succeed, and FWFRIENDLY is TRUE, then the client tries the PASV command. The PASSIVEIGNOREADDR value determines how the FTP client uses the IP address that is returned by the PASV command.

Syntax

Parameters

FALSE

For passive mode FTP, specifies that the FTP client uses the IP address and port number from the PASV command reply that is returned by the FTP server for the data connection. This is the default value.

TRUE

For passive mode FTP, specifies that the FTP client uses the port number from the PASV command reply, and the IP address used to log into the FTP server, for the data connection.

Guideline: If your client has trouble establishing a data connection on an IPv4 encrypted session through a NAT firewall, and the FTP server does not support extended passive mode, coding PASSIVEIGNOREADDR TRUE might help.

Requirement: FWFRIENDLY must also be set to TRUE to enable this function.

Examples

To direct the client to ignore the IP address on the FTP server's PASV reply, use the following code:

```
PASSIVEIGNOREADDR TRUE
```

Related topics

- “EPSV4 (FTP client) statement” on [page 681](#)
- “FWFRIENDLY (FTP client) statement” on [page 689](#)

PASSIVEONLY (FTP client) statement

Use the PASSIVEONLY statement to enable or disable passive mode only support for data connections.

Syntax

Parameters

FALSE

Data connections for the client are not passive mode only. When passive mode attempt fails, the client tries active mode. This is the default.

TRUE

Data connections for the client are passive mode only.

Example

To enable PASSIVEONLY support for data connections for the client, code the following:

```
PASSIVEONLY TRUE
```

Usage notes

This parameter is honored only when EPSV4 or FWFRIENDLY is specified and in effect.

Related topics

- [“EPSV4 \(FTP client\) statement” on page 681](#)
- [“FWFRIENDLY \(FTP client\) statement” on page 689](#)

PASSPHRASE (FTP server) statement

Use the PASSPHRASE statement to indicate whether the FTP server allows an FTP client to log in to FTP with a password phrase.

Syntax

Parameters

TRUE

The FTP server allows an FTP client to log in to FTP with a password phrase. This is the default value.

FALSE

The FTP server does not allow an FTP client to log in to FTP with a password phrase.

Examples

To allow an FTP client to log in to FTP with a password phrase, code the following statement:

```
PASSPHRASE TRUE
```

Usage notes

When PASSPHRASE FALSE is configured in FTP.DATA of the server, consider the following two things:

- If an FTP client logs in to FTP with a password of a length that is greater than 8 characters, the password is truncated to 8 characters.

- The FTCHKPWD exit parameter at offset +36 points to a buffer that consists of a 2-byte field, which contains zeros, and is followed by 100 blanks.

PDSTYPE (FTP client and server) statement

Use the PDSTYPE statement in the FTP server and client to indicate whether to allocate MVS directories as partitioned data sets or as partitioned data sets extended. You can also use the SIte and LOCSItE subcommands to set this keyword.

This is one of many statements available to control how MVS directories are allocated when the server receives an MKD command with an MVS PDS name argument.

You should specify PDSTYPE without the PDS or PDSE parameters if the DATACLASS statement is specified and the PDS type from the SMS data class is going to be used.

Server

This setting applies when creating an MVS directory on the server's system.

Client

This setting applies when creating an MVS directory on the client's system.

Syntax

Parameters

PDS

Allocate MVS directories as partitioned data sets.

PDSE

Allocate MVS directories as partitioned data sets extended.

Note: If neither PDS or PDSE specified, the default is PDSTYPE.

Examples

Set the directory type to partitioned data set extended:

```
PDSTYPE PDSE
```

Specify PDSTYPE with no value to obtain the PDS type from an SMS data class.

- [“SECONDARY \(FTP client and server\) statement” on page 735](#)

- [“SPACETYPE \(FTP client and server\) statement” on page 765](#)

PORTCOMMAND (FTP server) statement

Use the PORTCOMMAND statement to specify whether the PORT command is accepted or rejected. If REJECT is coded, this limits the use of commands such as GET, PUT, MPUT, MGET, and APPEND in PROXY mode. If not in PROXY mode, and REJECT is coded, the FTP server uses the same ephemeral port for the data connection that is used for the control connection. When issuing multiple commands that use the data connection, delays can occur.

Syntax

Parameters

ACCEPT

The PORT and EPRT commands are accepted by the server.

REJECT

The PORT and EPRT commands are rejected by the server.

When PORTCOMMAND is set to REJECT, all PORT and EPRT commands are rejected. PORTCOMMANDPORT and PORTCOMMANDIPADDR settings are disregarded.

Examples

Setting the server to reject all PORT and EPRT commands is shown in the following example:

```
PORTCOMMAND REJECT
```

Related topics

- [“PORTCOMMANDIPADDR \(FTP server\) statement” on page 718](#)
- [“PORTCOMMANDPORT \(FTP server\) statement” on page 719](#)

PORTCOMMANDIPADDR (FTP server) statement

Use the PORTCOMMANDIPADDR statement to direct the server to accept only PORT or EPRT commands whose IP address matches that of the client.

Syntax

Parameters

UNRESTRICTED

If PORTCOMMAND is set to ACCEPT or unspecified, the server accepts any IP address as a parameter for the PORT and EPRT commands.

NOREDIRECT

If PORTCOMMAND is set to ACCEPT or unspecified, the server rejects any PORT or EPRT command whose IP address does not match that of the client.

Examples

Setting the server to reject all PORT or EPRT commands with an IP address different from the IP address of the control connection is shown in the following example:

```
PORTCOMMAND ACCEPT
PORTCOMMANDIPADDR NOREDIRECT
```

Usage notes

When PORTCOMMAND is set to REJECT, all PORT and EPRT commands are rejected. PORTCOMMANDPORT and PORTCOMMANDIPADDR settings are disregarded.

Related topics

- [“PORTCOMMAND \(FTP server\) statement” on page 718](#)
- [“PORTCOMMANDPORT \(FTP server\) statement” on page 719](#)

PORTCOMMANDPORT (FTP server) statement

Use the PORTCOMMANDPORT statement to specify what range of port values the server accepts as a parameter for the PORT or EPRT command.

Syntax

Parameters

UNRESTRICTED

If PORTCOMMAND is set to ACCEPT or unspecified, the server accepts any port number as a parameter for the PORT or EPRT command.

NOLOWPORTS

If PORTCOMMAND is set to ACCEPT or unspecified, the server rejects any PORT or EPRT command specifying a port number lower than 1024.

Examples

Setting the server to reject all PORT or EPRT commands with a port number less than 1024 is shown in the following example:

```
PORTCOMMAND ACCEPT
PORTCOMMANDPORT NOLOWPORTS
```

Usage notes

When PORTCOMMAND is set to REJECT, all PORT and EPRT commands are rejected. PORTCOMMANDPORT and PORTCOMMANDIPADDR settings are disregarded.

Related topics

- [“PORTCOMMAND \(FTP server\) statement” on page 718](#)
- [“PORTCOMMANDIPADDR \(FTP server\) statement” on page 718](#)

PORTOFENTRY4 (FTP server) statement

Use the PORTOFENTRY4 statement to specify the resource profile class name the FTP server should have the USS kernel pass to the security server during login processing for IPv4 clients.

Syntax

Parameters

TERMINAL

The IPv4 client address is always passed as an 8-byte hexadecimal character string resource name in the TERMINAL class.

SERVAUTH

If the IPv4 client address is mapped into a network security zone by a NETACCESS statement in the TCP/IP PROFILE, the netaccess resource name in the SERVAUTH class is passed. If the client address is not mapped, the TERMINAL class resource name is passed.

Examples

To pass SERVAUTH resource names when mapped, use the following code:

```
PORTOFENTRY4 SERVAUTH
```

Related topics

For more information about network access control and port of entry access control with the FTP server, see [z/OS Communications Server: IP Configuration Guide](#).

PRIMARY (FTP client and server) statement

Use the PRIMARY statement to specify the number of tracks, blocks, or cylinders (according to SPACETYPE) for primary allocation.

Server

This setting applies when creating data sets on the server's system.

Client

This setting applies when creating data sets on the client's system.

Syntax

Parameters

amount

The number of tracks, blocks, or cylinders. The valid range is 1 - 16 777 215 blocks (the operating system maximum). The default is 1.

- If you specify no value for the *amount* parameter, FTP does not specify the number of tracks, blocks, or cylinders for primary allocation.
- You should specify no value for the *amount* parameter if the DATACLASS statement is specified and the space allocation from the SMS data class is to be used. If the SMS data class is to be used for space allocation, both the PRIMARY and SECONDARY values must be omitted and the value on the SPACETYPE statement is ignored.

Restriction: If a UNIX file (such as /etc/ftp.data) is being used as the configuration input and no value for the *amount* parameter is specified, the statement should not have any trailing blanks. Ensure that the line ends after the PRIMARY keyword or that a comment is also specified.

- For allocating partitioned data sets, *amount* is the quantity that is allocated for the primary extent.
- For allocating sequential data sets, *amount* is the maximum quantity that is allocated for the primary extent. If a lesser amount is needed to hold the data being transferred, the unused amount is released after the transfer is complete.

Examples

Set the primary allocation to 5 tracks:

```
PRIMARY 5
```

PROGRESS (FTP client) statement

Use the PROGRESS (FTP client) statement to control the interval between progress report messages generated by the FTP client during an inbound or outbound file transfer.

Client

This setting applies when transferring data to or from the FTP client.

Syntax

Parameters

seconds

Specifies the interval in seconds between progress report messages generated in the FTP client during an inbound or outbound file transfer. Valid values are in the range 10 - 86400, or 0. A value of 0 turns progress reporting off in the FTP client. The default value is 10 seconds. Messages EZA2509I and EZA1485I are generated as part of progress reporting. These messages are generated automatically at 10-second intervals by the FTP client in releases prior to V1R6. Beginning in V1R6, the default behavior is the same as in prior releases, but the length of the interval and whether to generate the messages can be configured by using the PROGRESS parameter setting on the locsite subcommand or by specifying the PROGRESS statement in FTP.DATA.

Examples

To set the progress reporting interval to 30 seconds, use the following code:

```
PROGRESS 30
```

QUOTESOVERRIDE (FTP client and server) statement

Use the QUOTESOVERRIDE statement to indicate the usage of single quotation marks appearing at the beginning of or surrounding a file name.

Server

This setting applies to the processing of names by the server.

Client

This setting applies to the processing of names by the client.

Syntax

Parameters

TRUE

If TRUE is specified, single quotation marks appearing at the beginning and end of a file name are interpreted as meaning the file name contained inside the single quotation marks should override the current working directory instead of being appended to the current working directory. Any single quotation marks inside the beginning and ending quotation mark are treated as part of the file name. This is the default.

FALSE

If FALSE is specified, a single quote at the beginning of the file name, as well as all other single quotation marks contained in the file name, is treated as part of the actual file name. The entire file name, including the leading single quote, is appended to the current working directory.

Examples

To treat quotation marks as part of file names, enter the following code:

```
QUOTESOVERRIDE FALSE
```

RDW (FTP client and server) statement

Record Descriptor Words (RDWs) are the first 4 bytes at the start of a variable record length file that tell the reading program the actual length of the current record being read. Use the RDW statement to specify whether the RDW from variable format data sets should be retained as data and transmitted or not transmitted.

Server

This setting applies when transferring data sets from the server's system.

Client

This setting applies when transferring data sets from the client's system.

Syntax

Parameters

TRUE

Record descriptor words are transferred as data. FTP returns the RDWs as part of the data for variable record format data sets. Depending upon the FTP implementation, RDWs might not be handled as the user expects. For example, the z/OS Communications Server FTP client might treat received RDWs as as carriage control/line feeds.

FALSE

Record descriptor words are not transferred with the data.

Examples

To specify that a variable record format file's data is transmitted without the descriptors showing the way it was stored on z/OS, use the following code:

```
RDW FALSE
```

Related topics

[“RECFM \(FTP client and server\) statement” on page 723](#)

RECFM (FTP client and server) statement

Use the RECFM statement to specify the record format of new, dynamically allocated data sets.

Server

This setting applies when creating data sets on the server's system.

Client

This setting applies when creating data sets on the client's system.

Syntax

Parameters

format

The record format of a data set. Valid record formats are:

- F
- FM
- FA
- FS
- FSA
- FSM
- FB
- FBM
- FBA
- FBS
- FBSM
- FBSA
- V
- VM
- VA
- VS
- VSM
- VSA
- VB
- VBM
- VBA
- VBS
- VBSA
- VBSM
- U
- UA
- UM

The default record format is VB. The meanings of the record formats are:

Format

Description

A

Records contain ISO/ANSI control.

B

Blocked records.

- F** Fixed record length.
- M** Records contain machine code control characters.
- S** Spanned records (if variable) or Standard (if fixed).
- U** Undefined record length.
- V** Variable record length characters.

Examples

Use fixed blocked record format:

```
RECFM FB
```

Specify RECFM with no value to allow the RECFM value of a DCB data set or an SMS dataclass to be used:

```
RECFM
```

Usage notes

- If you specify no value for *format*, no record format is specified when allocating new data sets.
- The record format attribute can be obtained from an SMS data class using the DATACLASS statement, from a model data set using the DCBDSN statement, or from the RECFM statement.
- You should specify no value for *format* if you:
 - Specify the DATACLASS statement and the record format from the SMS data class is to be used, or
 - Specify the DCBDSN and the record format from the model data set is to be used.
- If you specify both a DATACLASS and a DCBDSN, and you specify RECFM with no value, the record format attribute is obtained from the model data set.
- You can override the record format attribute from the DATACLASS or DCBDSN settings by specifying RECFM with a value, or by not specifying the RECFM statement and taking the default.

Related topics

- [“DCBDSN \(FTP client and server\) statement” on page 667](#)
- [“DSNTYPE \(FTP client and server\) statement” on page 673](#)
- [“EATTR \(FTP client and server\) statement” on page 678](#)
- See the information about storage management subsystem (SMS) in [z/OS Communications Server: IP Configuration Guide](#) for more information about specifying attributes when allocating new data sets.

REMOVEINBOF (FTP client and server) statement

Use the REMOVEINBOF statement to specify whether the z/OS UNIX EOF (x'1A') is removed from inbound data before the data is stored.

This setting applies to type ASCII inbound file transfers when the data is stored into an MVS sequential data set.

Server

This setting applies when the server is the receiving site.

Client

This setting applies when the client is the receiving site.

Syntax

Parameters

TRUE

Specifies that if the inbound data contains a z/OS UNIX EOF (x'1A') as the final byte, it is removed from the data.

FALSE

Specifies that if the inbound data contains a z/OS UNIX EOF (x'1A') as the final byte, it is not removed from the data.

Examples

Remove the UNIX EOF from the inbound data:

```
REMOVEINBEF TRUE
```

REPLY226 (FTP server) statement

Use the `REPLY226` statement to direct the FTP server to reply to the FTP client with reply code 226 instead of reply code 250 to command sequences described in RFC 959; these command sequences enable the server to choose between reply code 226 and reply code 250.

Tips:

- FTP reply codes are described in RFC 959.
- Generally, reply code 226 or 250 is used after a successful file transfer, after `LIST` commands, and after `NLST` commands.
- Reply code 250 (but not 226) is used for a broader class of FTP commands, such as `RNTO`, `DELE`, `MKD`, `RMD`, `CWD`.
- RFC 959 describes the command sequences where a server is allowed to reply with either reply code 226 or reply code 250.

Syntax

Parameters

FALSE

Directs the server to reply to the client with code 250 after successful file transfer, and after other FTP commands that enable the server to choose between reply code 250 and reply code 226. This is the default.

TRUE

Directs the server to reply to the client with reply code 226 instead of reply code 250 after successful file transfer, and after other FTP commands that enable the server to choose between reply code 250 and reply code 226.

Restriction: A server is not always permitted to select reply 226 instead of reply 250. The REPLY226 setting does not override RFC 959 in these cases. For example, RFC 959 stipulates the server must reply with reply code 250 to RMD (remove directory); the REPLY226 setting does not affect the reply code selected for RMD commands.

Examples

To direct the client to reply with code 226 instead of code 250 for successful file transfer, and for other command sequences described in RFC 959 that enable the server to choose between reply code 226 and reply code 250, enter the following code in the server's FTP.DATA:

```
REPLY226 TRUE
```

REPLYSECURITYLEVEL (FTP server) statement

Use the REPLYSECURITYLEVEL statement to specify whether or not to include secure information, such as IP addresses and port numbers, in FTP replies.

Syntax

Parameters

REPLYSECURITYLEVEL 0

No restrictions are placed on information included in server FTP replies. This is the default.

REPLYSECURITYLEVEL 1

No IP addresses, hostnames, port numbers, or server operating system level information is included in FTP replies.

Examples

Direct the server not to divulge secure information such as IP addresses and port numbers in replies to the client:

```
REPLYSECURITYLEVEL 1
```

Usage notes

Suppressing sensitive information such as IP addresses from client replies increases the security of your site; however, such information can be useful for debugging. An alternative to getting this information from server replies is to activate the server trace to capture this information. See [z/OS Communications Server: IP Diagnosis Guide](#) for information about diagnosing problems with server traces.

Related topics

[“DEBUG \(FTP client and server\) statement” on page 668](#)

RESTGET (FTP client) statement

Use the RESTGET statement to specify whether the FTP client should open the checkpoint data set for a GET request.

Syntax

Parameters

TRUE

Specifies that the checkpoint data set is opened for a GET request. This is the default.

FALSE

Specifies that the checkpoint data set is not opened for a GET request.

Examples

```
RESTGET FALSE ; do not open the checkpoint data set
```

Usage notes

The FTP client opens the checkpoint data set for a GET or MGET request when the following conditions are met:

- The data type is EBCDIC
- The file type is SEQ
- The transmission mode is either block or compressed
- The UNIXFILETYPE value is FILE when the local file is a z/OS UNIX file

Guideline: Use RESTGET FALSE to prevent the open of the data set. If the data set is not opened, a failed data transfer in block or compressed mode cannot be restarted.

Related topics

- [“CHKPTINT \(FTP client and server\) statement” on page 652](#)
- [“CHKPTPREFIX \(FTP client\) statement” on page 654](#)
- See REStart subcommand information in [z/OS Communications Server: IP User's Guide and Commands](#).
- [“UNIXFILETYPE \(FTP client and server\) statement” on page 784](#)

RESTPUT (FTP server) statement

Use the RESTPUT statement to specify whether the server supports checkpoint and restart processing when receiving data (put operation).

Server

This setting applies when the server is the receiving site.

Syntax

Parameters

TRUE

Specifies that the server supports checkpoint and restart processing when receiving data. This is the default.

FALSE

Specifies that the server does not support checkpoint and restart processing when receiving data. This means that restart markers sent by the client are not supported. When this value is specified, a failed data transfer in block or compressed mode cannot be restarted.

Examples

Use the following code to specify that checkpoint and restart processing should not be supported when the server is receiving data:

```
RESTPUT FALSE
```

Related topic

- [“CHKPTINT \(FTP client and server\) statement” on page 652](#)

RETPD (FTP client and server) statement

Use the RETPD statement to specify the number of days a newly allocated data set should be retained. You can also use the SIte and LOCSItE subcommands to set this keyword.

Server

This setting applies when creating data sets on the server's system.

Client

This setting applies when creating data sets on the client's system.

Syntax

Parameters

days

The number of days a newly allocated data set should be retained. The valid range is 0 - 9 999. The default is no retention period assigned to the data set.

If you specify 0 for *days*, newly allocated data sets are assigned a retention period of 0 days. This means that the retention period of the data set expires on the same day that the data set is created.

If you do not specify the RETPD statement or if you specify the RETPD statement with no value, no retention period is assigned to newly allocated data sets.

However, you should understand that the retention period attribute can be obtained from an SMS data class (DATACLASS), an SMS management class (MGMTCLASS), a model data set (DCBDSN), or from the RETPD statement.

You should specify no value for *days* if one of the following situations is true:

- The DATACLASS statement is specified and the retention period from the SMS data class is to be used.
- The MGMTCLASS statement is specified and the retention period from the SMS management class is to be used.
- The DCBDSN statement is specified and the retention period from the model data set is to be used.

If you specify RETPD with a value, this value overrides the retention period settings from any specified model data set (DCBDSN) or SMS data class (DATACLASS) and might override the value of a specified SMS management class (MGMTCLASS).

You should specify no value for *days* if one of the following situations is true:

- The DATACLASS statement is specified and the retention period from the SMS data class is to be used.
- The MGMTCLASS statement is specified and the retention period from the SMS management class is to be used.
- The DCBDSN statement is specified and the retention period from the model data set is to be used.

If you specify RETPD with no value, and you specified both an SMS data class and a model data set, then the retention period is obtained from the model data set.

If the SMS data class or DCBDSN model data set have a retention period, this retention period can be overridden to a new retention period. The retention period cannot be overridden to have no assigned retention period.

If you specify a management class, then the retention period is obtained from the management class. The value of the management class's retention period can be overridden.

- If a data class is specified, the retention period in the data class can override it.
- If a model data set (DCBDSN) is specified, its retention period overrides both the data class value and the management class value.
- If you specify RETPD with a value, the value you specify overrides any data class setting, model data set value, and any management class setting.

However, regardless of where the retention period value is obtained, when attempting to override the value set in the management class, the actual resulting retention period setting depends on the retention period limit defined in the management class. A management class is defined with a retention limit value as well as a retention period. If you attempt to override the management class's retention period, the override value must be within the retention period limit defined in the management class. Otherwise, the retention period used is the management class's retention limit value.

Examples

- Make the new data set expiration date equal to 30 days:

```
RETPD 30
```

- Use a retention period of 0 days:

```
RETPD 0
```

- See the information about storage management subsystem (SMS) in [z/OS Communications Server: IP Configuration Guide](#) for more information about specifying attributes when allocating new data sets.

SBDATACONN (FTP client and server) statement

This statement defines the conversions between file system code pages and network transfer code pages to be used for data transfer. You can also use the `Site` and `LOCSite` subcommands to set this keyword.

Server

Specifies the single-byte code pages used by the server for data connections.

Client

Specifies the single-byte code pages used by the client for data connections.

Syntax

Parameters

dsname

The fully qualified name of an MVS data set or z/OS UNIX file containing the file system to network transfer translate table and the network transfer to file system translate table generated by the `CONVXLAT` utility. For more information about translation tables, see [Appendix A, “Translation tables,” on page 1303](#).

file_system_codepage

The name of a code page that is recognized by `iconv`. The code page is used for data that is written in the file system.

network_transfer_codepage

The name of a code page that is recognized by `iconv`. The code page is used for data that is transferred on the network.

FTP_STANDARD_TABLE

Indicates that the FTP internal tables, which are the same as the tables that are shipped in `TCPXLBIN(STANDARD)`, are to be used.

Examples

```
SBDATACONN (IBM-037,IBM-858)
```

Usage notes

- If you specify `SBDATACONN (file_system_codepage,network_transfer_codepage)`, FTP uses the `iconv()` application programming interface to translate between the two code pages. The values that you enter on the `SBDATACONN` statement are used by FTP as parameters to the C++ runtime function `iconv()`. You

can find a valid list of code sets in the [z/OS XL C/C++ Programming Guide](#). See [“SBSUB \(FTP client and server\) statement” on page 733](#) and [“SBSUBCHAR \(FTP client and server\) statement” on page 734](#) for more information about using substitution characters to replace unmapped code points during the data transfer.

- The SYSFTSX DD statement, if present, overrides the SBADATACONN statement.
- If neither the SYSFTSX DD statement nor the SBADATACONN statement is present, the search order for a TCPXLBIN data set is followed. See [“SBCS translation table hierarchy” on page 1303](#) for this search order. If no TCPXLBIN data set is found, the same conversion established for the control connection is used for single-byte data transfer.

Related topics

- For the code pages supported by iconv(), see [z/OS XL C/C++ Programming Guide](#).
- [“SBSUBCHAR \(FTP client and server\) statement” on page 734](#)
- [“SBSSENDEOL statement \(FTP client and server\) statement” on page 732](#)
- [“SBSUB \(FTP client and server\) statement” on page 733](#)

SBSSENDEOL statement (FTP client and server) statement

Use the SBSSENDEOL statement to tell the FTP client or server what end-of-line (EOL) sequence to use for outbound data when ENcoding is SBCS, Mode is stream, and Type is ASCII. You can also use the SItE and LOCStE subcommands to set this keyword.

Server

Tell the server what EOL sequence to append to each line of text when ENcoding is SBCS, Type is ASCII, and files are sent from the server to the client.

Client

Tell the client what EOL sequence to append to each line of text when ENcoding is SBCS, Type is ASCII, and files are sent from the client to the server.

Syntax

Parameters

CRLF

When translating outbound single-byte data to ASCII, append a carriage return (x'0D') and line feed (x'0A') to each line of text. This is the default and the standard line terminator defined by RFC 959. The z/OS server and client can receive ASCII data in this format only. It is the only setting permitted when using the SRestart subcommand in the client.

CR

When translating outbound single-byte data to ASCII, append only a carriage return (x'0D') to each line of text.

LF

When translating outbound single-byte data to ASCII, append only a line feed (x'0A') to each line of text.

NONE

When translating outbound single-byte data to ASCII, append no EOL sequence.

Examples

When translating outbound single-byte data to ASCII, to append LF only to each line use the following code:

```
SBSENDEOL  LF
```

To translate files sent from the FTP client to ASCII, without appending an EOL sequence to each line, code the following statements in the client's FTP.DATA. At login, the data type is ASCII and the mode is Stream unless you change the values using subcommands.

```
ENCODING SBCS  
SBSENDEOL NONE
```

Restrictions:

- This statement applies only to the end-of-line sequence used on the data connection. The control connection end-of-line sequence is not affected.
- Double-byte, UCS-2, and multi-byte file transfers are not affected by this setting.
- This statement applies only when ENCODING is SBCS, Type is ASCII, and Mode is Stream.

Rule: The SBSENDEOL setting CRLF is the default and the standard EOL sequence defined by RFC 959. It is appropriate for most file transfers. Do not use an alternate SBSENDEOL setting unless you have verified that the recipient FTP can handle the alternate value.

Client

Do not code an alternate SBSENDEOL value if your server is a z/OS FTP server. The z/OS FTP server does not support alternate SBSENDEOL values for inbound file transfer.

Server

Do not code an alternate SBSENDEOL value if your client is a z/OS FTP client. The z/OS FTP client does not support alternate SBSENDEOL values for inbound file transfer.

Result for FTP client: If you put a file while TYPE is ASCII, MODE is STREAM, ENCODING is SBCS, and SBSENDEOL is not CRLF, the srestart put subcommand is disabled.

Results for FTP server:

- If you code a SBSENDEOL value other than CRLF, the SIZE command is disabled.
- If you transfer a file from the server while TYPE is ASCII, MODE is STREAM, ENCODING is SBCS, and SBSENDEOL is not CRLF, the SIZE command is disabled for the remainder of the session, and the command sequence REST - RETR is disabled for MODE STREAM, TYPE ASCII, ENCODING SBCS file transfers. This precludes stream-mode restart of file transfer to and from the server.
- The REST command in Mode B (Block mode) is not affected by this setting.

Related topics

- [“SBDFACONN \(FTP client and server\) statement” on page 731](#)
- [“ENCODING \(FTP client and server\) statement” on page 680](#)

SBSUB (FTP client and server) statement

Use the SBSUB statement in the server and client FTP.DATA to specify whether a substitution is allowed for data bytes that cannot be translated. You can also use the SItE and LOCStE subcommands to set this keyword.

Server

Specifies the whether substitution is allowed on the server's system.

Client

Specifies the whether substitution is allowed on the client's system.

Syntax**Parameters****FALSE**

Substitution is not allowed for single-byte character translation. This causes a data transfer failure if a character cannot be mapped during the transfer. This is the default value.

TRUE

Substitution is allowed for single-byte character translation. The SBSUBCHAR statement defines the substitution value for untranslatable characters.

Examples

To disable substitution for single-byte character translation, code the following:

```
SBSUB  FALSE
```

Related topics

- [“SBDATACONN \(FTP client and server\) statement” on page 731](#)
- [“SBSUBCHAR \(FTP client and server\) statement” on page 734](#)

SBSUBCHAR (FTP client and server) statement

Use the SBSUBCHAR statement in the server and client FTP.DATA to specify the substitution character for data transfers using SBCS encodings when SBSUB has a value of TRUE. You can also use the SItE and LOCStE subcommands to set this keyword.

Server

Specifies the substitution character on the server's system.

Client

Specifies the substitution character on the client's system.

Syntax

Parameters

SPACE

Specifies x'40' when target code set is an EBCDIC code set and x'20' when target code set is an ASCII code set. This is the default value.

nn

Hexadecimal value that represents a single-byte character. The value of nn can be from 00 to FF.

Examples

To indicate the substitution character to be x'40', use the following code:

```
SBSUBCHAR 40
```

Related topics

- [“SBADATACONN \(FTP client and server\) statement” on page 731](#)
- [“SBSUB \(FTP client and server\) statement” on page 733](#)

SBTRANS (FTP client) statement

Use the SBTRANS statement to specify the SBCS translation table to be used for the data connection. This table is used for SBCS and DBCS data transfers. FTP uses the translation table in the `user_id.dsn_qual.TCPXLBIN` data set. If the `user_id.dsn_qual.TCPXLBIN` data set does not exist, FTP uses the `hlq.dsn_qual.TCPXLBIN` data set.

Syntax

► SBTRANS — *dsn_qual* ◀

Parameters

dsn_qual

Specifies the data set qualifier used to name the translation table.

Examples

```
SBTRANS DATA ; use USER33.DATA.TCPXLBIN when ftp  
              ; is used by USER33
```

Usage notes

SBADATACONN and SBTRANS are mutually exclusive statements. If both statements appear in the FTP.DATA file, SBTRANS is ignored.

Related topics

[“SBADATACONN \(FTP client and server\) statement” on page 731](#)

SECONDARY (FTP client and server) statement

Use the SECONDARY statement to specify the number of tracks, blocks, or cylinders (according to SPACETYPE) for secondary allocation.

Server

This setting applies when creating data sets on the server's system.

Client

This setting applies when creating data sets on the client's system.

Syntax

Parameters

amount

The number of tracks, blocks, or cylinders. The valid range is 0 - 16 777 215 blocks (the operating system maximum). The default is 1.

- If you specify no value for *amount*, FTP does not specify the number of tracks, blocks, or cylinders for secondary allocation.
- You should specify no value for *amount* if the DATACLASS statement is specified and the space allocation from the SMS data class is to be used. If the SMS data class is to be used for space allocation, both the PRIMARY and SECONDARY values must be omitted, and the value on the SPACETYPE statement is ignored.

Restriction: If a UNIX file (such as /etc/ftp.data) is being used as the configuration input and no value for the *amount* parameter is specified, then the statement should not have any trailing blanks. Ensure that the line ends after the SECONDARY keyword or that a comment is also specified.

Examples

Set the secondary allocation to two tracks:

```
SECONDARY 2
```

- [“SPACETYPE \(FTP client and server\) statement” on page 765](#)

SECURE_CTRLCONN (FTP client and server) statement

Use the SECURE_CTRLCONN statement to indicate the security level for a control connection. This statement applies only to Kerberos.

Requirement: When using TLS, the control connection must be enciphered and this setting has no effect on the TLS behavior.

Terminology

Integrity protected, data integrity, or data authentication

Indicates that an algorithm is applied to the data being transferred, which modifies that data such that the receiving program can verify the data was not modified or changed during the transfer.

Privacy protected

Indicates that an algorithm is applied to the data being transferred, which encrypts or scrambles the data such that only the receiving program can use a special key to decrypt or unscramble the data to its original format. The original data cannot be seen or interpreted while the data is in transit.

Raw

Indicates that data is transmitted without being modified by any encryption or data integrity algorithms.

Encipher or cipher algorithm

Indicates that data being transferred is encrypted, integrity protected, or both. This term does not imply which algorithm is used and does not imply that it is encrypted.

Syntax

Parameters

Configuring an FTP server

CLEAR

Specifies that the client decides whether data is transferred raw, integrity protected only, or both integrity and privacy protected.

PRIVATE

Specifies that the server requires data to be transferred using both integrity and privacy protection. Clients attempting to send raw data or data integrity protect only are rejected.

SAFE

Specifies that the server requires data to be transferred using integrity protection only, or using both integrity and privacy protection. Clients attempting to send raw data are rejected.

Configuring an FTP client

CLEAR

Specifies that data can be transferred raw, integrity protected only, or both integrity and privacy protected.

By default, data is transferred raw. However, you can issue the **cprotect private** and **cprotect safe** commands during the FTP session to change the control connection security level. Issuing the **cprotect private** command changes the control connection security level so data is transferred both integrity and privacy protected. Issuing the **cprotect safe** command changes the control connection security level so data is transferred integrity protected only. Then, you can also issue the **cprotect clear** command to reset the control connection security level back, so that data is transferred raw again.

PRIVATE

Specifies that the client data is transferred both integrity and privacy protected.

SAFE

Specifies that the data can be transferred integrity protected only, or both integrity and privacy protected.

By default, data is transferred integrity protected only. However, the client can issue the **cprotect private** during the FTP session to change the control connection security level so data is transferred both integrity and privacy protected. The user can also issue the **cprotect safe** command to reset the control connection security level back, so that data is transferred integrity protected only.

Examples

```
SECURE_CTRLCONN PRIVATE
```

Requirements:

- You must code EXTENSIONS AUTH_GSSAPI for this statement to be used by the FTP server.
- You must code SECURE_MECHANISM GSSAPI for this statement to be used by the FTP client.

Restriction: This statement is ignored when the security mechanism is TLS.

Related topic

- “EXTENSIONS (FTP client and server) statement” on page 682

SECURE_DATACONN (FTP client and server) statement

Use the SECURE_DATACONN statement to indicate the level of security used on data connections, and it applies to both TLS and Kerberos.

See “SECURE_CTRLCONN (FTP client and server) statement” on page 736 for an explanation of terminology for protected, raw, and enciphered data.

Syntax

Parameters

Configuring an FTP server

NEVER

Indicates the server requires data to be transferred raw with no cipher algorithm applied to the data. Clients attempting to use ciphers are rejected.

CLEAR

Indicates the client decides whether data is transferred raw or enciphered.

For TLS, the client decides whether data is enciphered or not. If it indicates it should be enciphered, the cipher algorithm is chosen using TLS protocols.

For Kerberos, the client can specify whether data is transferred raw, integrity protected only, or both integrity and privacy protected.

PRIVATE

Indicates the server requires data to be transferred enciphered. Clients attempting to send raw data are rejected.

For TLS, the cipher algorithm is chosen using TLS protocols.

For Kerberos, the data must be transferred using both integrity and privacy protection. Clients attempting to send data that is only integrity protected are rejected.

SAFE

For TLS, specifying this option is identical to the PRIVATE specification.

For Kerberos, the data must be transferred using both integrity and privacy protected. Clients attempting to send data that is only integrity protected are rejected.

Configuring an FTP client

NEVER

Indicates the client requires data to be transferred raw with no cipher algorithm applied to the data.

CLEAR

Indicates the data can be transferred raw or enciphered.

By default, data is transferred raw. However, you can issue the **private** command during the FTP session to change the data connection security level so the data is enciphered. You can also issue the **clear** command to reset the data connection security level back, so that data is transferred raw again.

For TLS, if the **private** command is issued, the cipher algorithm is chosen using TLS protocols.

For Kerberos, if the **private** command is issued, data is transferred both integrity and privacy protected. In addition to the **private** and **clear** commands, you can issue the **safe** command to change the data connection security level so data is transferred integrity protected only.

PRIVATE

Indicates the client requires data to be transferred enciphered.

For TLS, the cipher algorithm is chosen using TLS protocols.

For Kerberos, the data must be transferred using both integrity and privacy protected.

SAFE

For TLS, specifying this option is identical to the PRIVATE specification.

For Kerberos, the data can be transferred integrity protected only, or both integrity and privacy protected. By default, data is transferred integrity protected only. However, you can issue the **private** command during the FTP session to change the data connection security level so data is transferred both integrity and privacy protected. You can also issue the **safe** command to reset the data connection security level back, so data is transferred integrity protected only.

Examples

```
SECURE_DATACONN NEVER
```

Usage notes

If the FTP server uses the secure port, the server behaves as if the value on this statement is PRIVATE. See [“TLSPORT \(FTP client and server\) statement”](#) on page 773 for information about the secure port.

SECURE_FTP (FTP client and server) statement

Use the SECURE_FTP statement to specify whether use of a security mechanism is optional or required.

Syntax

Parameters

Configuring an FTP server

REQUIRED

Specifies that all clients log in using a security mechanism.

Rules:

- If the server is enabled for TLS only, clients must log in using TLS.
- If the server is enabled for Kerberos only, clients must log in using Kerberos.
- If the server is enabled for both TLS and Kerberos, clients must log in using either TLS or Kerberos.

ALLOWED

Allows clients to log in using a security mechanism, but it is not required.

Rules:

- If the server is enabled for TLS only, clients must log in using TLS or no security mechanism.
- If the server is enabled for Kerberos only, clients must log in using Kerberos or no security mechanism.
- If the server is enabled for both TLS and Kerberos, clients must log in using TLS, Kerberos, or no security mechanism.

Configuring an FTP client

REQUIRED

Specify that a client log in must use a security mechanism. If the server does not support the client's security mechanism, the login fails and the client cannot log in.

Rules:

- If the client's security mechanism is TLS, clients must log in using TLS.
- If the client's security mechanism is Kerberos, clients must log in using Kerberos.

ALLOWED

Allow the client to log in using a security mechanism, but it is not required.

Rules:

- If the client's security mechanism is TLS, clients must log in using TLS. If the server does not support TLS, the server indicates this back to the client. The client then completes the log in, but without using TLS.
- If the client's security mechanism is Kerberos, clients must log in using Kerberos. If the server does not support Kerberos, the server indicates this back to the client. The client then completes the log in, but without using Kerberos.

Examples

```
SECURE_FTP ALLOWED
```

Usage notes

- If the FTP server used the secure port, the server behaves as if the value on this statement is required. See [“TLS/PORT \(FTP client and server\) statement” on page 773](#) for information about the secure port.
- This statement is valid for FTP servers if either EXTENSIONS AUTH_TLS or EXTENSIONS AUTH_GSSAPI is specified.
- This statement is valid for FTP clients if either SECURE_MECHANISM TLS or SECURE_MECHANISM GSSAPI is specified.

Related topics

- [“SECURE_MECHANISM \(FTP client\) statement” on page 744.](#)
- [“EXTENSIONS \(FTP client and server\) statement” on page 682.](#)

- See [z/OS Communications Server: IP Configuration Guide](#) for more information about [File Transfer Protocol](#) and [SSL/TLS](#).

SECURE_HOSTNAME (FTP client) statement

Use the SECURE_HOSTNAME statement to specify whether the client verifies the host name in the server's certificate.

The statement is ignored for sessions that are not protected by the TLS security mechanism.

Syntax

Parameters

REQUIRED

Specifies that the host name that the client is connecting to is verified against the server's certificate. Either the common name or the subject alternate name contained in the server's X.509 certificate is used to validate the host name. If the verification fails, the connection is terminated.

OPTIONAL

Specifies that the host name is not validated. This is the default.

SECUREIMPLICITZOS (FTP client and server) statement

Use the SECUREIMPLICITZOS statement to specify when FTP should negotiate or expect the security handshake for TLS/PORT implicitly secured connections.

Rules:

- To enable a z/OS FTP client to log into the z/OS FTP server using the protected port, specify the same SECUREIMPLICITZOS statement value and TLS/PORT value for the client and server.
- When using the implicit connection (FTP client is connecting to the port specified by the TLS/PORT statement), some FTP servers expect to negotiate the security of the session immediately

after the connection is issued. If you are initiating a secure session with such a server, code `SECUREIMPLICITZOS FALSE` in the client's FTP.DATA file.

- Many non-z/OS FTP clients negotiate the security immediately after the connect and before the initial 220 reply is received from the server. To enable these clients to log into the z/OS FTP server's protected port, code `SECUREIMPLICITZOS FALSE` in the server's FTP.DATA file.

Server

The first reply that the FTP server sends to a client uses reply code 220. The reply is sometimes referred to as the good morning reply. The `SECUREIMPLICITZOS` statement specifies whether the server expects the TLS handshake to occur before or after it sends the initial reply 220.

Client

The `SECUREIMPLICITZOS` statement specifies when the client initiates the TLS handshake for connections to the `TLSPORT` (protected port). You can change this setting using the `locsite` subcommand.

Syntax

Parameters

TRUE

This is the default.

Server

Specifies that the FTP server expects the security handshake to occur after it sends the reply 220.

Client

Specifies that the FTP client initiates the security handshake after the 220 (good morning) reply is received from the server.

FALSE

Server

Specifies that the FTP server expects the security handshake before it sends the reply 220.

Client

Specifies that the FTP client negotiates the security handshake immediately after the connection and before the initial 220 reply is received from the server.

Examples

To initiate an implicitly secured session between a z/OS FTP client and a z/OS FTP server, code the following statements in the FTP client and server FTP.DATA file:

```
SECUREIMPLICITZOS TRUE
```

You could also code the following statement in both the FTP client and server FTP.DATA file:

```
SECUREIMPLICITZOS FALSE
```

To initiate an implicitly secured session between a non-z/OS FTP client and a z/OS FTP server, code the following statement in the FTP server FTP.DATA file:

```
SECUREIMPLICITZOS FALSE
```

Related topic

- “[TLSPORT \(FTP client and server\) statement](#)” on page 773

SECURE_LOGIN (FTP server) statement

Use the SECURE_LOGIN statement to indicate whether the FTP server requires client authentication.

The SECURE_LOGIN statement setting applies to TLS and Kerberos. Note that the term certificate is actually TLS terminology. In Kerberos, the equivalent of a certificate is a ticket, which contains credentials.

Rules:

- This statement is valid only when you have coded EXTENSIONS TLS or EXTENSIONS AUTH in the FTP.DATA file of the server.
- If you code VERIFYUSER TRUE in FTP.DATA, the server verifies the user's access to the FTP server port profile in the SERVAUTH class regardless of the SECURE_LOGIN value.

Syntax

Parameters

VERIFY_USER

Indicates that in addition to client certificate authentication, the user's ID is further verified.

For Kerberos, the user ID in the client's ticket is verified to match the login user ID.

```
EZB.FTP.MVS164.FTPD1.PORT21
```

For TLS:

- The server verifies that the certificate has been registered with your SAF-compliant security product, such as RACF, and has an associated user ID matching the login user ID.
- If the SERVAUTH RACF (or another security product) class is active and a RACF resource has been defined for the port, the connection is allowed only if the user ID associated with the client certificate has READ access to the RACF resource.

The resource name would be:

```
EZB.FTP.<systemname>.<ftpddaemonname>.PORTxxxxx
```

where xxxxx is replaced by the port number for the FTP daemon. For example, if the procedure FTPD is used to start the daemon on system MVS164 and the daemon uses the default FTP port 21, then the resource name is:

```
EZB.FTP.MVS164.FTPD1.PORT21
```

Tip: For sessions that are not secured with TLS, you can use the same resource profile to control which users can log into the FTP server when you code VERIFYUSER TRUE in the server's FTP.DATA file. However, if you do code VERIFYUSER TRUE in FTP.DATA, the server verifies the user's access to the resource profile regardless of the SECURE_LOGIN value.

REQUIRED

Indicates that the server should authenticate client certificates.

This does not affect Kerberos behavior; Kerberos always processes the client's ticket.

For TLS, client certificate authentication occurs during the SSL handshake. To pass authentication, the Certificate Authority (CA) that signed the client certificate must be considered trusted by the server. This means a certificate for the CA that issued the client certificate is listed as trusted in the server's key ring.

NO_CLIENT_AUTH

Specifies that the server should not request the client certificate for TLS.

This parameter has no effect for Kerberos.

Examples

```
SECURE_LOGIN REQUIRED
```

- [“SECURE_SESSION_REUSE \(FTP client and server\) statement” on page 749](#)

SECURE_MECHANISM (FTP client) statement

Use the SECURE_MECHANISM statement to specify whether the FTP client should use a security mechanism when a session is established. The parameter on the statement indicates which security mechanism to use.

Syntax

➤ SECURE_MECHANISM  TLS
GSSAPI

Parameters

TLS

Specifies that TLS is the security mechanism that is used by the client when it establishes a session.

GSSAPI

Specifies that GSSAPI is the security mechanism that is used by the client when it establishes a session.

Examples

To specify that TLS protocols should be use for the session, use the following code:

```
SECURE_MECHANISM TLS
```

Usage notes

- Security mechanism GSSAPI is supported for IPv4 connections only.

- The SECURE_MECHANISM statement can be overridden by the -a or the -r start parameter on the FTP command.

Related topics

- [“SECURE_FTP \(FTP client and server\) statement” on page 739.](#)

- See the FTP command and the FTP environment information in [z/OS Communications Server: IP User's Guide and Commands](#).
- See [z/OS Communications Server: IP Configuration Guide](#) for more information about [File Transfer Protocol](#) and [SSL/TLS](#).

SECURE_PASSWORD (FTP server) statement

Use the SECURE_PASSWORD statement to specify whether a password is required by the FTP server for an TLS protected session. The statement is ignored for sessions that are not protected by the TLS security mechanism.

Syntax

Parameters

REQUIRED

Specifies that a password is required to log in a user whose session is protected by the TLS security mechanism.

OPTIONAL

Specifies that the password is not required if the client provides a certificate that can be used to authenticate the user. See the Usage notes in this topic for more information.

If the client certificate is used to authenticate the user and the authentication fails, the login attempt fails.

Rule: The handshake that occurs when the TLS protected session is established must include the transfer of the client certificate to the server. If you code SECURE_PASSWORD OPTIONAL, you must code SECURE_LOGIN VERIFY_USER or SECURE_LOGIN REQUIRED to require the client certificate.

Result: If you code SECURE_PASSWORD OPTIONAL and SECURE_LOGIN NO_CLIENT_AUTH in the FTP.DATA file, the message EZYFS16I is logged to inform you that the combination is not allowed. The value set by the SECURE_PASSWORD statement is changed to REQUIRED.

Examples

To require the user to enter a password on an TLS protected session only when the USER name does not match the name associated with the certificate, code the following statements:

```

SECURE_LOGIN      REQUIRED
SECURE_PASSWORD   OPTIONAL

```

Usage notes

The certificate that is received from the client must be registered in the security product and must be associated with the user ID that is passed on the USER command to the FTP server. You can use RACDCERT ADD command to register and associate the certificate.

When the certificate is registered in the security product and is associated with the user ID that is passed in on the USER command, the SECURE_PASSWORD statement value determines the action taken during the login procedure.

Table 47 on page 746 shows the statement value options.

Table 47. SECURE_PASSWORD statement value options		
SECURE_PASSWORD	SECURE_LOGIN	Action
REQUIRED	VERIFY_USER or REQUIRED	Prompt for a password.
OPTIONAL	VERIFY_USER or REQUIRED	Authenticate with the certificate (do not prompt for password if the authenticate fails).

When either the certificate is not registered in the security product or is not associated with the user ID that is passed in on the USER command, the SECURE_LOGIN statement value determines the action during the login procedure.

Table 48 on page 746 shows the statement value options.

Table 48. SECURE_LOGIN statement value options		
SECURE_PASSWORD	SECURE_LOGIN	Action
REQUIRED or OPTIONAL	VERIFY_USER	Fail the login.
REQUIRED or OPTIONAL	REQUIRED	Prompt for a password.

Related topics

- [“EXTENSIONS \(FTP client and server\) statement” on page 682.](#)
- [“SECURE_LOGIN \(FTP server\) statement” on page 743.](#)

- See [z/OS Communications Server: IP Configuration Guide](#) for more information about [File Transfer Protocol](#) and [SSL/TLS](#).

SECURE_PASSWORD_KERBEROS (FTP server) statement

Use the `SECURE_PASSWORD_KERBEROS` statement to specify whether a password is required by the FTP server for a Kerberos-protected session. The statement is ignored for sessions that are not protected by the Kerberos security mechanism.

Rule: This statement is enabled only when `EXTENSIONS AUTH_GSSAPI` is coded in the server's `FTP.DATA` file.

When the user ID passed on the `USER` command matches the user ID that the SAF-compliant security product maps to the user ID that the Kerberos principal received from the client, the `SECURE_PASSWORD_KERBEROS` statement value determines whether the server prompts the client for the password during the login procedure.

Syntax

Parameters

REQUIRED

Specifies that a password is required to log in a user whose session is protected by the Kerberos security mechanism.

This is the default.

OPTIONAL

Specifies that the password is not required if the user ID passed on the `USER` command matches the user ID that the SAF-compliant security product mapped to the user ID that the Kerberos principal received from the client.

Examples

To require the user to enter a password on a Kerberos-protected session only when the user ID passed on the `USER` command does not match the user ID that the SAF-compliant security product mapped to the user ID that the Kerberos principal received from the client, code the following statement:

```
SECURE_PASSWORD_KERBEROS  OPTIONAL
```

Usage notes

Table 49 on page 747 shows how the `SECURE_PASSWORD_KERBEROS` statement affects user authentication when the user ID to which the Kerberos principal is mapped matches the user ID that is passed on the `USER` command.

Table 49. User identity in the Kerberos ticket matches user ID on <code>USER</code> command		
SECURE_PASSWORD_KERBEROS	SECURE_LOGIN	Action
REQUIRED	One of the following: <ul style="list-style-type: none"> • <code>VERIFY_USER</code> • <code>REQUIRED</code> • <code>NO_CLIENT_AUTH</code> 	Prompt for a password.

Table 49. User identity in the Kerberos ticket matches user ID on USER command (continued)		
SECURE_PASSWORD_KERBEROS	SECURE_LOGIN	Action
OPTIONAL	One of the following: <ul style="list-style-type: none"> • VERIFY_USER • REQUIRED • NO_CLIENT_AUTH 	Authenticate with the Kerberos ticket (if the Kerberos authentication fails, fail the login, do not prompt for password).

When the user ID to which the Kerberos principal is mapped does not match the user ID that is passed on the USER command, the SECURE_LOGIN statement value determines the action that is necessary during the authentication procedure.

Table 50 on page 748 shows how the SECURE_LOGIN statement affects user authentication when the user ID to which the Kerberos principal is mapped does not match the user ID that is passed on the USER command.

Table 50. User identity in the Kerberos ticket does not match user ID on USER command		
SECURE_PASSWORD_KERBEROS	SECURE_LOGIN	Action
REQUIRED or OPTIONAL	VERIFY_USER	Fail the login.
REQUIRED or OPTIONAL	REQUIRED or NO_CLIENT_AUTH	Prompt for a password.

SECURE_PBSZ (FTP client and server) statement

Specifies the maximum size of the encoded data blocks sent during file transfer.

Server

Specifies the maximum protection buffer size the server accepts.

Client

Specifies the protection buffer size the client uses to negotiate with the server.

Syntax

Parameters

buffer_size

The valid range is between 512 - 32 768. The default value is 16 384.

Usage notes

- The client initially issues the PBSZ command specifying *buffer_size*. If the PBSZ command is rejected, the client reissues the PBSZ command with a smaller value until it is accepted by the server.
- If the server receives a protection buffer size (PBSZ) larger than the value configured in the server's FTP.DATA configuration file, the server defaults to its configured value.
- The setting applies only to the Kerberos protocol.

Related topics

- [“EXTENSIONS \(FTP client and server\) statement” on page 682](#)
- [“SECURE_MECHANISM \(FTP client\) statement” on page 744](#)
- [“SECURE_SESSION_REUSE \(FTP client and server\) statement” on page 749](#)

SECURE_SESSION_REUSE (FTP client and server) statement

Use the SECURE_SESSION_REUSE statement to specify whether the FTP client and server require session reuse when SSL/TLS is used to protect the connections.

Server

Specifies whether the server requires session reuse when SSL/TLS is used to protect the connections.

Client

Specifies whether the client requires session reuse when SSL/TLS is used to protect the connections.

Syntax

Server syntax

Client syntax

Parameters

ALLOWED

Specifies that reusing the SSL session ID of either the control connection or a previous data connection on subsequent data connections within an FTP session is enabled. The FTP client and server reuse the session ID of the control connection when the FTP client and server perform the SSL handshake for subsequent data connections. If the session ID of the control connection cannot be reused, a full SSL handshake is used for the current data connection. The FTP client and server reuse the session ID of the current data connection on subsequent data connections.

REQUIRED

Specifies that reusing the SSL session ID of the control connection on subsequent data connections within an FTP session is required. The FTP client and server must reuse the session ID of the control connection when the FTP client and server perform the SSL handshake for subsequent data connections. If the session ID of the control connection cannot be reused, the SSL handshake for the data connection fails.

NONE

Specifies that reusing the SSL session ID of either the control connection or a previous data connection on the subsequent data connections within an FTP session is not enabled.

Note: This parameter applies to the FTP client only. The FTP server always reuses the SSL session ID of either the control connection or a previous data connection on subsequent data connections. Specifying NONE on the server is regarded as a syntax error and the default value of ALLOWED is used.

Examples

To enable session reuse for the client when SSL/TLS is used to protect the connections, code the following statement:

```
SECURE_SESSION_REUSE ALLOWED
```

To require session reuse for the server when SSL/TLS is used to protect the connections, code the following statement:

```
SECURE_SESSION_REUSE REQUIRED
```

Usage notes

- For FTP client and server, if the control connection SSL session is not reused because of a small cache size or timeout value, the following situations might occur:
 - Long running jobs with large number of data connections might fail during one SSL data connection setup.
 - Long running SSL data connections for big data transfer might fail during the SSL renegotiation.
- For FTP client and server, if the SECURE_SESSION_REUSE value is set to REQUIRED and the remote side does not support reusing the session ID, data connections and FTP transfers will fail.
- You can control the SSL cache timeout value in FTP.
 - When you use the TLSMECHANISM statement with the ATTLS parameter specified, the GSK_V3_SESSION_TIMEOUT statement in the relevant TTLSGskAdvancedParms statement configures how long SSL sessions remain in the cache. For the FTP client, if the SECURE_SESSION_REUSE value is set to ALLOWED or REQUIRED, the GSK_V3_SESSION_TIMEOUT value must not be 0; otherwise, the SSL handshake fails. For the FTP server, if the SECURE_SESSION_REUSE value is set to ALLOWED, the GSK_V3_SESSION_TIMEOUT value cannot be 0; otherwise, an SSL session might not be cached and then reused. If the SECURE_SESSION_REUSE value is set to REQUIRED, the GSK_V3_SESSION_TIMEOUT value must not be 0; otherwise, the SSL handshake fails.

- When you use the TLSMECHANISM statement with the FTP parameter specified, the TLSTIMEOUT statement in the FTP.DATA file configures how long SSL sessions remain in the cache. For the FTP client, if the SECURE_SESSION_REUSE value is set to ALLOWED or REQUIRED, TLSTIMEOUT value must not be 0; otherwise, the SSL handshake fails.
- TLSMECHANISM FTP is only for the client. The server always uses AT-TLS if SECURE_MECHANISM TLS is specified

SEQNUMSUPPORT (FTP client) statement

Use the SEQNUMSUPPORT statement to ignore sequence numbers in files designated by the ddname INPUT.

Syntax

Parameters

TRUE

When reading FTP subcommands to be processed from the ddname INPUT, FTP removes any sequence numbers before processing the command.

FALSE

When reading FTP subcommands, any sequence numbers in the input designated by the ddname INPUT are considered to be part of the input. This is the default.

Examples

The following example shows how data sets with different sequence number schemes can be concatenated if SEQNUMSUPPORT TRUE is coded in the FTP.DATA file:

Suppose dataset: FTP.SUBCMDS(LOGIN) contains no sequence numbers

```
mvs056.tcp.raleigh.ibm.com
user1
us3rpswd
```

Suppose dataset: FTP.SUBCMDS(FTPINFO) contains TRAILING sequence numbers

```
; This comment prevents 00000100 and subsequent sequence numbers      00000100
; from being interpreted as an ftp subcommand.                          00000110
locstat                                                                    00000120
stat                                                                       00000130
```

```

pwd                                                    00000140

Suppose dataset:  FTP.SUBCMDS(FTPCMSD1) contains no sequence numbers

; This comment indicates no sequence numbers present
get remote.file.name local.name.

Suppose dataset:  FTP.SUBCMDS(FTPCMSD2) contains LEADING sequence numbers

00000100; The file indicates leading sequence numbers present
00000110put local.file +
00000120 remote.file

```

To specify the datasets listed previously as input to the FTP client, the following sample JCL is used:

```

//FTP EXEC PGM=FTP
//SYSPRINT DD SYSOUT=*
//SYSFTPD DD DSN=SYS1.TCPPARMS(FTPCDATA),DISP=SHR
//* Insure that SEQNUMSUPPORT TRUE is coded
//* in the above clients FTP.DATA file
//INPUT DD DSN=FTP.SUBCMDS(LOGIN),DISP=SHR
//        DD DSN=FTP.SUBCMDS(FTPINFO),DISP=SHR
//        DD DSN=FTP.SUBCMDS(FTPCMSD1),DISP=SHR
//        DD DSN=FTP.SUBCMDS(FTPCMSD2),DISP=SHR

```

Results:

- When SEQNUMSUPPORT TRUE is coded in the FTP.DATA file and the FTP client reads the first record of the file specified by the ddname INPUT, the record determines the type of sequence numbers that are to be processed.
- If the last eight columns are numeric and contain trailing sequence numbers, this data is replaced with blanks before running this and subsequent records. Otherwise, if the first eight columns are numeric and contain leading sequence numbers, the data that begins in column 9 is shifted to column 1 before the record is processed.
- If FTP detects no sequence numbers, the data is not modified.
- Each time a semicolon (;) is detected in the first data column, FTP determines the sequencing mode to use to process sequence numbers that follow statement.

Requirements:

- If you concatenate files with the INPUT DD statement, the first statement in each concatenated file must have a semicolon (;) in column 1; the semicolon enables the FTP client to correctly determine the sequence numbering scheme that is being used.
- If no semicolon (;) is present in the concatenated files, sequence number processing does not change.

SMF (FTP server) statement

Use the SMF statement to specify SMF recording for all FTP server subtypes (see Usage notes).

Syntax

Parameters

STD

Indicates that all FTP server SMF records of type 118 are issued with the following subtypes:

- APPEND - 70

- DELETE - 71
- LOGIN FAILURE - 72
- RENAME - 73
- RETRIEVE - 74
- STORE - 75
- STORE UNIQUE - 75

number

The SMF record subtype to be used for all FTP server records unless otherwise specified for a particular record subtype. The valid range is 1 - 255. There is no default value.

Restriction: This field applies to type 118 records only.

TYPE119

Indicates that all FTP server SMF records of type 119 are issued. Type 119 records have the following subtypes:

- APPEND - 70
- DELETE - 70
- DAEMON CONFIGURATION -71
- LOGIN FAILURE - 72
- RENAME - 70
- RETRIEVE - 70
- STORE - 70
- STORE UNIQUE - 70

Examples

To have all 118 FTP server records created with standard subtypes:

```
SMF STD
```

To have all type 119 FTP server records created:

```
SMF TYPE119
```

To have all type FTP server records of both types created with standard subtypes for type 118 records:

```
SMF STD
SMF TYPE119
```

To log all FTP records of type 119, as well as type 118 APPEND records:

```
SMF TYPE119
SMFAPPE 99
```

To log all FTP records of type 118 with standard subtypes, as well as type 119 DELETE and RENAME records:

```
SMF STD
SMFDEL TYPE119
SMFREN TYPE119
```

Usage notes

- SMF statements for each record type (118 and 119) function independently of each other.

- If the SMF statement is omitted, SMF recording occurs for only the events with a statement coded. For example, if SMF is omitted but an SMFAPPE statement is coded, only the APPEND command has SMF recording.
- If the SMF statement is coded with a value of STD, all other SMF-related statements using type 118 records with a value coded (even if it is STD) are flagged with warning message EZYFT58 and their specifications are ignored. SMF STD means standard type 118 values and no other type 118 values are allowed.

For example, if SMF STD is specified, then specifying SMFAPPE STD is flagged with message EZYFT58 and is ignored.

- Records for transfer actions when using FILETYPE=JES are not recorded unless the SMFJES statement is also specified.
- Records for transfer actions when using FILETYPE=SQL are not recorded unless the SMFSQL statement is also specified.
- If none of the SMF subtype statements are coded in the FTP.DATA data set, then no SMF records are written by the FTP server.
- Records of type 118 and type 119 can both be requested; however, do not do this due to performance implications of writing both record types. Use type 119 records instead of type 118 records, as type 119 records generally use more standard formatting and provide more information.

SMFAPPE (FTP server) statement

Use the SMFAPPE statement to specify the SMF record subtype to be used for the APPE (APPEND) command.

Syntax

Parameters

STD

Indicates that type 118 SMF APPEND records are issued with the standard subtype of 70.

number

Indicates that type 118 SMF APPEND records are issued with the given record subtype. The valid range is 1 - 255.

TYPE119

Indicates that type 119 SMF APPEND records are issued (subtype 70).

Examples

Set the type 118 SMF record subtype for APPEND to 70:

```
SMFAPPE 70
```

To issue type 119 SMF APPEND records:

```
SMFAPPE TYPE119
```

Usage notes

- SMFAPPE statements for each record type (118 and 119) function independently of each other.
- If you do not specify the SMFAPPE statement for a particular record type (118 or 119), SMF Append records of that type are still issued if the corresponding SMF statement for that record type is present.

SMFDCFG (FTP server) statement

Use the SMFDCFG statement to specify that a type 119 SMF record of subtype 71 is collected for the FTP daemon configuration information when the FTP daemon starts.

Syntax

➤ SMFDCFG ➤

Parameters

The SMFDCFG statement has no parameters. If you use the SMFDCGF statement with a parameter, the parameter is ignored.

Examples

To record FTP daemon configuration information when the FTP daemon starts, use the following statement:

```
SMFDCFG
```

Usage notes

- If you do not specify the SMFDCFG statement, the SMF record for the FTP daemon configuration information is issued only when the SMF TYPE119 statement is present. If neither the SMF nor the SMFDCFG statement is specified, no SMF records are collected for the FTP daemon configuration information.
- Only type 119 SMF records are available for FTP daemon configuration information. No corresponding type 118 SMF records are available.

- [“SMFSTOR \(FTP server\) statement” on page 763](#)

SMFDEL (FTP server) statement

Use the SMFDEL statement to specify SMF recording options for the DELE (DELETE) command.

Syntax

Parameters

STD

Indicates that type 118 SMF DELETE records are issued with the standard subtype of 71.

number

Indicates that type 118 SMF DELETE records are issued with the given record subtype. The valid range is 1 - 255.

TYPE119

Indicates that type 119 SMF DELETE records are issued (subtype 70).

Examples

Set the type 118 SMF record subtype for DELETE to 71:

```
SMFDEL 71
```

To issue type 119 SMF DELETE records:

```
SMFDEL TYPE119
```

Usage notes

- SMFDEL statements for each record type (118 and 119) function independently of each other. To collect both types, you must specify both SMFDEL STD and SMFDEL TYPE119.
- If you do not specify the SMFDEL statement, SMF records for the DELETE command are still issued if the SMF statement is present. (Type 118 DELETE records have the subtype specified with the SMF statement; type 119 DELETE records are always subtype 70.) If neither the SMF or SMFDEL statement is specified, no SMF records are collected for the DELETE command.
- Records for the SMFDEL statement when using FILETYPE=JES are not recorded unless the SMFJES statement is also specified.
- Records for the SMFDEL statement when using FILETYPE=SQL are not recorded unless the SMFSQL statement is also specified.

SMFEXIT (FTP server) statement

Use the SMFEXIT statement to specify that the user exit routine FTPSMFEX is called before writing the Type 118 SMF record to SMF data sets.

Syntax

➤ SMFEXIT ➤

Parameters

This statement has no parameters.

Examples

To specify that the user exit FTPSMFEX is called before writing the Type 118 SMF record to SMF data sets, use the following code:

Usage notes

The FTP SMF user exit has been discontinued for type 119 FTP SMF records. The user exit routine FTPSMFEX is only to be called for any type 118 records that are written; no FTP-specific exit is called for type 119 records. In order to obtain the same functionality with type 119 records, the system-wide SMF user exits should now be used (IEFU83, IEFU84, and IEFU85). See [z/OS MVS System Management Facilities \(SMF\)](#) for more information.

SMFJES (FTP server) statement

Use the SMFJES statement to specify that SMF records are collected when FILETYPE is JES (remote job submission).

If SMFJES is not specified, no SMF records are issued when FILETYPE is JES.

Syntax

```

▶▶ SMFJES —————▶
      |
      | TYPE119
      |

```

Parameters

TYPE119

Issue records for filetype JES for all type 119 SMF records. If no parameters are given, records for filetype JES are issued for all type 118 SMF records.

Examples

To record SMF type 118 records for STOR when FILETYPE=JES, use the following code:

```

SMFSTOR STD
SMFJES

```

To record SMF type 119 records for STOR when FILETYPE=JES, use the following code:

Usage notes

SMFJES statements for each record type (118 and 119) function independently of each other.

Related topics

- [“FILETYPE \(FTP client and server\) statement” on page 686](#)
- [“JESINTERFACELEVEL \(FTP server\) statement” on page 694](#)

SMFLOGN (FTP server) statement

Use the SMFLOGN statement to specify the SMF recording options when recording logon failures.

Syntax

Parameters

STD

Indicates that type 118 SMF logon failure records are issued with the standard subtype of 72.

number

Indicates that type 118 SMF logon failure records are issued with the given record subtype. The valid range is 1 - 255.

TYPE119

Indicates that type 119 SMF logon failure records are issued (subtype 72).

Examples

Set the type 118 SMF record subtype for logon failures to 72:

```
SMFLOGN 72
```

To issue type 119 SMF LOGON records:

```
SMFLOGN TYPE119
```

Usage notes

- There is no default value; however, if the SMF statement is coded for type 118 records, the value specified for the SMF statement is used as the default.
- SMFLOGN statements for each record type (118 and 119) function independently of each other.
- If you do not specify the SMFLOGN statement, SMF records for logon failures are still issued if the SMF statement is present (type 118 logon failure records have the subtype specified with the SMF statement; type 119 logon failure records are always subtype 72). If neither the SMF or SMFLOGN statement is specified, no SMF records are collected for logon failures.

SMFREN (FTP server) statement

Use the SMFREN statement to specify SMF recording options for the RNFR/RNTO (RENAME) command.

Syntax

Parameters

STD

Indicates that type 118 SMF RENAME records are issued with the standard subtype of 73.

number

Indicates that type 118 SMF RENAME records are issued with the given record subtype. The valid range is 1 - 255.

TYPE119

Indicates that type 119 SMF RENAME records are issued (subtype 70).

Examples

Set the type 118 SMF record subtype for RENAME to 73:

```
SMFREN 73
```

To issue type 119 SMF RENAME records:

Usage notes

- There is no default value; however, if the SMF statement is coded for type 118 records, the value specified for the SMF statement is used as the default.
- SMFREN statements for each record type (118 and 119) function independently of each other.
- If you do not specify the SMFREN statement, SMF records for the RENAME command is still issued if the SMF statement is present (type 118 RENAME records have the subtype specified with the SMF statement; type 119 RENAME records are always subtype 70). If neither the SMF or SMFREN statement is specified, no SMF records are collected for the RENAME command.
- Records for the SMFREN statement when using FILETYPE=JES are not recorded unless the SMFJES statement is also specified.
- Records for the SMFREN statement when using FILETYPE=SQL are not recorded unless the SMFSQL statement is also specified.

SMFRETR (FTP server) statement

Use the SMFRETR statement to specify SMF recording options for the RETR (RETRIEVE) command.

Syntax

Parameters

STD

Indicates that type 118 SMF RETRIEVE records are issued with the standard subtype of 74.

number

Indicates that type 118 SMF RETRIEVE records are issued with the given record subtype. The valid range is 1 - 255.

TYPE119

Indicates that type 119 SMF RETRIEVE records are issued (subtype 70).

Examples

Set the type 118 SMF record subtype for RETRIEVE to 74:

```
SMFRETR 74
```

To issue type 119 SMF RETRIEVE records:

```
SMFRETR TYPE119
```

Usage notes

- There is no default value; however, if the SMF statement is coded for type 118 records, the value specified for the SMF statement is used as the default.
- SMFRETR statements for each record type (118 and 119) function independently of each other.
- If you do not specify the SMFRETR statement, SMF records for the RETRIEVE command are still issued if the SMF statement is present. (Type 118 RETRIEVE records have the subtype specified with the SMF statement; type 119 RETRIEVE records are always subtype 70.) If neither the SMF or SMFRETR statement is specified, no SMF records are collected for the RETRIEVE command.
- Records for the SMFRETR statement when using FILETYPE=JES are not recorded unless the SMFJES statement is also specified.
- Records for the SMFRETR statement when using FILETYPE=SQL are not recorded unless the SMFSQL statement is also specified.

SMFSQL (FTP server) statement

Use the SMFSQL statement to specify that SMF records are collected when FILETYPE is SQL (SQL query function).

If SMFSQL is not specified, no SMF records are issued when FILETYPE is SQL.

Syntax

➤ SMFSQL — TYPE119

Parameters

TYPE119

Issue records for filetype SQL for all type 119 SMF records. If no parameters are given, records for filetype SQL are issued for all type 118 SMF records.

Examples

To record SMF type 118 records for RETR when FILETYPE=SQL, use the following code:

```
SMFRETR STD  
SMFSQL
```

To record SMF type 119 records for RETR when FILETYPE=SQL, use the following code:

```
SMFRETR TYPE119  
SMFSQL TYPE119
```

Usage notes

SMFSQL statements for each record type (118 and 119) function independently of each other.

Related topics

SMFSTOR (FTP server) statement

Use the SMFSTOR statement to specify SMF recording options for the STOR (STORE) and STOU (STORE UNIQUE) commands

Syntax

Parameters

STD

Indicates that type 118 SMF STORE and STORE UNIQUE records are issued with the standard subtype of 75.

number

Indicates that type 118 SMF STORE and STORE UNIQUE records are issued with the given record subtype. The valid range is 1 - 255.

TYPE119

Indicates that type 119 SMF STORE and STORE UNIQUE records are issued (subtype 70).

Examples

Set the type 118 SMF record subtype for STORE and STORE UNIQUE records to 75:

```
SMFSTOR 75
```

To issue type 119 SMF STORE and STORE UNIQUE records:

```
SMFSTOR TYPE119
```

Usage notes

- There is no default value; however, if the SMF statement is coded for type 118 records, the value specified for the SMF statement is used as the default.
- SMFSTOR statements for each record type (118 and 119) function independently of each other.
- If you do not specify the SMFSTOR statement, SMF records for the STORE and STORE UNIQUE commands are still issued if the SMF statement is present. (Type 118 STORE and STORE UNIQUE records have the subtype specified with the SMF statement; type 119 STORE and STORE UNIQUE records are always subtype 70.) If neither the SMF or SMFSTOR statement is specified, no SMF records are collected for the STORE and STORE UNIQUE commands.
- Records for the SMFSTOR statement when using FILETYPE=JES are not recorded unless the SMFJES statement is also specified.
- Records for the SMFSTOR statement when using FILETYPE=SQL are not recorded unless the SMFSQL statement is also specified.

SOCKSCONFIGFILE (FTP client) statement

Use the SOCKSCONFIGFILE statement to identify the SOCKS server configuration file the FTP client uses to determine which FTP servers require SOCKS protocols.

Syntax

➤ SOCKSCONFIGFILE — file-path ➤

Parameters

file-path

The z/OS UNIX absolute pathname or the fully qualified MVS data set name of the SOCKS configuration file. In accordance with the convention for absolute pathnames, a z/OS UNIX pathname must begin with a slash (/) character. Any file path not beginning with a slash character is considered a fully qualified MVS data set name.

Examples

To direct the client to use the file /etc/ftp/socks.conf for the SOCKS server configuration, specify the following code:

```
SOCKSCONFIGFILE /etc/ftp/socks.conf
```

To direct the client to use the data set 'socks.config' for the SOCKS server configuration, specify one of the following code:

```
SOCKSCONFIGFILE socks.config
```

```
SOCKSCONFIGFILE 'socks.config'
```

Usage notes

- If no SOCKSCONFIGFILE statement is specified, the client does not use SOCKS protocols during connection establishment.
- If the client is connecting to an IPv6 node, the client does not use SOCKS protocols during connection establishment.
- The server ignores the SOCKSCONFIGFILE statement.

Related topic

- [“SOCKS configuration statements in SOCKSCONFIGFILE” on page 792](#)

SPACETYPE (FTP client and server) statement

Use the SPACETYPE statement to specify whether newly allocated data sets are allocated in blocks, cylinders, or tracks.

Server

This setting applies when creating files on the server's system.

Client

This setting applies when creating files on the client's system.

Syntax

Parameters

BLOCK

Use blocks when allocating new data sets.

CYLINDER

Use cylinders when allocating new data sets.

TRACK

Use tracks when allocating new data sets. This is the default.

Examples

Allocate data sets in tracks:

```
SPACETYPE TRACK
```

Usage notes

If you do not supply values on the PRIMARY and SECONDARY statements in order to use the SMS data class, the value on the SPACETYPE statement is ignored and SMS determines the spacetype.

Related topics

- [“PRIMARY \(FTP client and server\) statement” on page 720](#)
- See the information about storage management subsystem (SMS) in [z/OS Communications Server: IP Configuration Guide](#) for more information about specifying attributes when allocating new data sets.
- [“SECONDARY \(FTP client and server\) statement” on page 735](#)

SPREAD (FTP client and server) statement

Use the SPREAD statement to specify whether or not the output is in spreadsheet format when the file type is SQL.

Server

This setting applies when format is output from the server.

Client

This setting applies when format is output from the client.

Syntax

Parameters

TRUE

Specifies the output is in spreadsheet format.

FALSE

Specifies the output is not in spreadsheet format. This is the default.

Examples

Format the output to spreadsheet format:

```
SPREAD TRUE
```

Related topics

- [“DB2 \(FTP client and server\) statement” on page 665](#)
- [“DB2PLAN \(FTP client and server\) statement” on page 666](#)
- [“FILETYPE \(FTP client and server\) statement” on page 686](#)
- [“SQLCOL \(FTP client and server\) statement” on page 767](#)

SQLCOL (FTP client and server) statement

Use the SQLCOL statement to specify the column headings of the output file when FILETYPE is SQL.

Server

This setting applies when format is output from the server.

Client

This setting applies when format is output from the client.

Syntax

Parameters

ANY

Use the label, but if there is no label, the name becomes the column heading.

LABELS

Use the label of the column headings. If any of the columns do not have labels, the server uses *COLnumber*, where *number* is the column number reading left to right.

NAMES

Use the name of the column headings and ignore the labels. This is the default.

Examples

Use the label of the column headings:

```
SQLCOL LABELS
```

Related topics

- [“DB2 \(FTP client and server\) statement” on page 665](#)
- [“DB2PLAN \(FTP client and server\) statement” on page 666](#)

- [“SPREAD \(FTP client and server\) statement” on page 766](#)

SSLV3 (FTP client connection) statement

Use the SSLV3 statement to enable or disable SSLV3 support for connections that are secured using TLS implemented by FTP (TLSMECHANISM FTP).

Syntax

Parameters

FALSE

Specifies that SSLV3 is disabled. This is the default.

TRUE

Specifies that SSLV3 is enabled.

Examples

To enable SSLV3 support for connections that are secured using TLS implemented by FTP, code the following statement:

```
SSLV3 TRUE
```

Usage notes

SSLV3 is honored only when TLSMECHANISM FTP is specified.

STARTDIRECTORY (FTP server) statement

Use the STARTDIRECTORY statement to specify which file system is initially used when a new user logs in.

Syntax

Parameters

HFS

Use the z/OS UNIX hierarchical file system. The initial directory is the user's root directory in the z/OS UNIX file.

MVS

Use MVS partitioned data sets. The initial data set name has a prefix of the user ID. See [initial working directory consideration](#) in [z/OS Communications Server: IP User's Guide and Commands](#) for more information.

Examples

Set the initial user directory to the user's root directory in the z/OS UNIX:

```
STARTDIRECTIONS HFS
```

Usage notes

The value of STARTDIRECTIONS must be compatible with the ANONYMOUSFILEACCESS value when anonymous logins are enabled and ANONYMOUSLEVEL is 3 or greater.

For example, if ANONYMOUSLEVEL is 3, ANONYMOUSFILEACCESS is MVS, and STARTDIRECTIONS is z/OS UNIX, anonymous users receive a filetype error when they attempt to log in to FTP. The anonymous login is rejected by the FTP server.

Related topics

- [“ANONYMOUSFILEACCESS \(FTP server\) statement” on page 632](#)
- [“ANONYMOUSLEVEL \(FTP server\) statement” on page 638](#)

STORCLASS (FTP client and server) statement

Use the STORCLASS statement to specify the SMS storage class as defined by your organization for the FTP server.

Server

This setting applies when transferring files from the server's system.

Client

This setting applies when transferring files from the client's system.

Syntax

```
STORCLASS — class
```

Parameters

class

The SMS storage class.

Examples

Use the SMS storage class SMSSTOR when allocating new data sets:

```
STORCLASS SMSSTOR
```

Related topics

- [“DATACLASS \(FTP client and server\) statement” on page 661](#)
- See the information about storage management subsystem (SMS) in [z/OS Communications Server: IP Configuration Guide](#) for more information about specifying attributes when allocating new data sets.

- [“UCOUNT \(FTP client and server\) statement” on page 779](#)
- [“VOLUME \(FTP client and server\) statement” on page 788](#)

SUPPRESSIGNOREWARNINGS (FTP client and server) statement

Use the SUPPRESSIGNOREWARNINGS statement to specify whether FTP issues message EZYFT47I each time it ignores a statement coded in FTP.DATA.

Server

This setting applies when starting the FTP server.

Client

This setting applies when starting the FTP client.

Syntax

Parameters

TRUE

Specifies that FTP does not issue message EZYFT47I when ignoring statements coded in FTP.DATA.

Guideline: Do not set SUPPRESSIGNOREWARNINGS TRUE until you have verified that the statements in your FTP.DATA configuration file are correct.

FALSE

Specifies that FTP issues message EZYFT47I when ignoring statements coded in FTP.DATA. This is the default.

Examples

Suppress message EZYFT47I while processing statements in FTP.DATA:

```
SUPPRESSIGNOREWARNINGS TRUE
```

Usage notes

- SUPPRESSIGNOREWARNINGS affects only statements in FTP.DATA that follow it. Therefore, code SUPPRESSIGNOREWARNINGS TRUE ahead of any statements for which you do not want the EZYFT47I warning.

- You can suppress EZYFT47I for some, but not all, statements in a single FTP.DATA file, by coding more than one SUPPRESSIGNOREWARNINGS statement. Each instance of SUPPRESSIGNOREWARNINGS is respected, so use it multiple times in FTP.DATA to toggle suppression of warning messages on and off.

TAPEREADSTREAM (FTP server) statement

Use the TAPEREADSTREAM statement to specify whether to use a more efficient read path (read as stream) to retrieve tape data sets from the server.

Results: The TAPEREADSTREAM statement takes effect when all of the following conditions are met:

- The file structure is File.
- The transfer mode is Stream.
- One of the following situations is true:
 - The transfer type is E
 - The transfer type is B
 - The transfer type is A and the encoding is SBCS
- The file type is not SQL.

Restrictions: When TAPEREADSTREAM TRUE is configured at the server:

- You cannot retrieve American Standards Association (ASA) tape data sets. The server responds with an error reply if you attempt to retrieve an ASA tape data set.
- You cannot retrieve fixed format tape data sets when TRAILINGBLANKS TRUE is configured. The server responds with an error reply if you attempt to retrieve a fixed format tape data set when TRAILINGBLANKS TRUE is configured.
- If the tape data set contains <NL> characters that require translation, the data set format will be incorrect.

Syntax

Parameters

FALSE

Use a common read path for tape data sets. This is the default value.

TRUE

Use a more efficient read path for tape data sets.

Examples

To use a more efficient read path for tape data sets:

```
TAPEREADSTREAM TRUE
```

TLSCERTCROSSCHECK (FTP client and server) statement

Use the TLSCERTCROSSCHECK statement to control whether FTP performs cross-checking of the certificates to validate that the certificate presented on the control connection is the same certificate presented on the data connection. This checking is performed only when FTP is secured by TLS.

Syntax

Parameters

TRUE

FTP performs cross-checking to validate whether the certificates on the control connection and on the data connection are the same. This is the default.

FALSE

FTP does not perform cross-checking of the certificates.

Examples

To disable certificate cross-checking support, code the following statement:

```
TLSCERTCROSSCHECK FALSE
```

Related topics

- [“EXTENSIONS \(FTP client and server\) statement” on page 682](#)
- [“SECURE_FTP \(FTP client and server\) statement” on page 739](#)
- [“SECURE_MECHANISM \(FTP client\) statement” on page 744](#)
- See [z/OS Communications Server: IP Configuration Guide](#) for more information about [SSL/TLS security](#), [key rings](#), and [certificates](#) and [SSL/TLS](#).

TLSMECHANISM (FTP client and server) statement

Use the `TLSMECHANISM` statement to specify whether TLS is implemented by AT-TLS or by FTP. AT-TLS is the preferred method for implementing TLS.

Server

This setting specifies how TLS security is implemented on the server host. Only AT-TLS is supported for the server. This statement is valid for FTP servers if `EXTENSIONS AUTH_TLS` is specified.

Client

This setting specifies how TLS security is implemented on the client host. This statement is valid for FTP clients if `SECURE_MECHANISM TLS` is specified.

Syntax Server

Syntax Client

Parameters

FTP

Specifies that secure mechanism TLS is defined by FTP.

Requirement: The KEYRING statement is required if secure mechanism TLS is defined by FTP.

ATTLS

Specifies that secure mechanism TLS is performed by AT-TLS.

Requirement: AT-TLS must be configured in the TCPIP stack. See [z/OS Communications Server: IP Configuration Guide](#) for more information.

Restriction: The KEYRING, CIPHERSUITE, SSLv3, and TLSTIMEOUT statements are ignored when using AT-TLS.

Examples

```
TLSMECHANISM FTP
```

Related topics

- “EXTENSIONS (FTP client and server) statement” on page 682
- “SECURE_FTP (FTP client and server) statement” on page 739
- “SECURE_MECHANISM (FTP client) statement” on page 744
- See [z/OS Communications Server: IP Configuration Guide](#) for more information about [SSL/TLS security](#), [key rings](#), and [certificates](#) and [SSL/TLS](#).

TLSPORT (FTP client and server) statement

Use the TLSPORT statement to set the secure port on which the FTP client or the FTP server implicitly protects the FTP session with TLS.

If you want to use port 990 for unsecured FTP sessions, use this statement to select a different secure port for implicit secure FTP sessions. If you want to disable support for implicit secure FTP, use a value of 0.

Syntax

Parameters

port

The port number used for implicit secure FTP sessions. The default is 990. The range of valid values is 0 - 65534.

Result: The specification of a TLS`PORT` does not cause the server to listen on that port, it only specifies that when the port is used it will behave as an implicit TLS port. See [“FTP server cataloged procedure \(FTPD\) parameters” on page 589](#) for information about how to specify the port for the listener.

Examples

```
TLSPORT 0
```

Related topics

[“SECUREIMPLICITZOS \(FTP client and server\) statement” on page 741](#)

TLSRFCLEVEL (FTP client and server) statement

Use the TLSRFCLEVEL statement to specify the level of RFC 4217 (*Securing FTP with TLS*) that FTP supports. You can also use the locsite subcommand to set this keyword. For information about RFCs, see Appendix C, “Related protocol specifications,” on page 1349.

Server

This setting applies when EXTENSIONS AUTH_TLS is coded in the server's FTP.DATA file.

Client

This setting applies when SECURE_MECHANISM TLS is coded in the client's FTP.DATA file.

Restrictions:

- FTP supports the TLS`PORT` statement regardless of the TLSRFCLEVEL setting. FTP connections to the TLS`PORT` are implicitly secured with TLS as described in the internet draft.
- The TLSRFCLEVEL parameters must be the same on the FTP client and server when using the RFC4217 parameter. If the parameters are different, connections might be reset or sessions appear to lock up and eventually timeout.
- The CCCNONOTIFY option is not valid with TLSMECHANISM ATTLS. If CCCNONOTIFY is required for the server partner system, configure TLSMECHANISM FTP for the client with associated statements and exemption in the TTLSRules.

Syntax

Syntax Server

Syntax Client

Parameters

DRAFT

Specifies that FTP supports the Internet-draft revision of RFC 4217. This is the level of RFC 4217 support that z/OS FTP has offered since Communications Server V1R2. This is the default.

Guideline: Specify this option, or allow it to default, to maintain the pre-V1R9 support for FTP TLS-protected sessions.

RFC4217

Specifies that FTP supports RFC 4217.

CCCNONOTIFY

Specifies that FTP does not issue the TLSshutdown after sending or receiving the CCC command. RFC 4217 did not mandate this flow until Internet draft revision 14.

Examples

Code this statement in the client's FTP.DATA file to enable RFC 4217 compliance:

```
TLRSRFCLEVEL RFC4217
```

Related topics

- [“TLSPORT \(FTP client and server\) statement” on page 773](#)
- See [z/OS Communications Server: IP Configuration Guide](#) for more information about [SSL/TLS security](#), [key rings](#), and [certificates](#).

TLSTIMEOUT (FTP client) statement

Use the TLSTIMEOUT statement to set a timeout for TLS handshake processing, when you use TLSMECHANISM FTP for the client. This timeout is the maximum time between full TLS handshakes. If this time period has not been reached since the last full handshake, a partial handshake occurs when a data connection is protected by TLS.

Syntax

➤ TLSTIMEOUT — *seconds* ➤

Parameters

seconds

The number of seconds in the range 0 - 86 400. Any value outside of this range reverts to the default of 100.

Examples

```
TLSTIMEOUT 60
```

Related topics

- [“EXTENSIONS \(FTP client and server\) statement” on page 682](#)
- [“SECURE_MECHANISM \(FTP client\) statement” on page 744](#)

- “[TLSMECHANISM \(FTP client and server\) statement](#)” on page 772

TLSV1 (FTP client) statement

Use the TLSV1 statement to enable or disable TLSV1 support for connections that are secured using TLS implemented by FTP (TLSMECHANISM FTP).

Syntax

Parameters

FALSE

Specifies that TLSV1 is disabled. This is the default.

TRUE

Specifies that TLSV1 is enabled.

Examples

To enable TLSV1 support for connections that are secured using TLS implemented by FTP, code the following statement:

```
TLSV1 TRUE
```

Usage notes

TLSV1 is honored only when TLSMECHANISM FTP is specified.

TRACE (FTP client and server) statement

Use the TRACE statement to start tracing for FTP.

Server

The trace output is written to syslog.

Client

The trace output is written to stdout.

Syntax

```
➤ TRACE ➤
```

Parameters

This statement has no parameters.

Examples

To specify that FTP server trace output should be directed to syslog, code the following in the server's FTP.DATA:

Usage notes

- TRACE is equivalent to entering DEBUG BAS or to entering the following four DEBUG statements:
 - DEBUG CMD
 - DEBUG INT
 - DEBUG FSC
 - DEBUG SOC

Note that tracing can have a major performance impact on FTP. Consider using the DEBUG statements to request only the kinds of general traces that are needed.

Related topic

- “[DEBUG \(FTP client and server\) statement](#)” on page 668

TRACECAPI (FTP client) statement

Use the TRACECAPI statement to define a control for tracing for a user-written program that uses the FTP client application programming Interface (API) to the z/OS FTP client. This interface is described in [z/OS Communications Server: IP Programmer's Guide and Reference](#).

Syntax

Parameters

CONDITIONAL

Specifies that tracing by the FTP client API of requests from a user program is conditional. Tracing is based on the setting of the FCAI_TraceIt field prior to issuing the request to the interface. This is the default.

ALL

Specifies that all requests are traced by the FTP client API.

NONE

Specifies that none of the requests are traced by the FTP client API.

Examples

To specify that all requests are traced, use the following code:

```
TRACECAPI  ALL
```

Related topics

For more information about the FTP Client Application Programming Interface (API), see the FTP client API information in [z/OS Communications Server: IP Programmer's Guide and Reference](#).

TRAILINGBLANKS (FTP client and server) statement

Use the TRAILINGBLANKS statement to specify whether trailing blanks in a fixed format data set are transferred when the data set is transferred.

Server

This setting applies when the server is the sending site.

Client

This setting applies when the client is the sending site.

Syntax

Parameters

TRUE

Specifies that the trailing blanks in a fixed format data set are included when the data set is sent.

FALSE

Specifies that the trailing blanks in a fixed format data set are not sent. This is the default.

Examples

Send the fixed format data set and include trailing blanks:

```
TRAILINGBLANKS TRUE
```

TRUNCATE (FTP client and server) statement

Use the TRUNCATE statement to specify what action should be taken if WRAPRECORD FALSE is specified, and it is determined that an input record is longer than the LRECL of the new file.

Server

This setting applies when transferring files to the server's system.

Client

This setting applies when transferring files to the client's system.

Syntax

Parameters

TRUE

Specifies that TRUNCATING records is allowed. Even if it is determined that records were truncated, file transfer continues and a warning message is issued when the transfer is complete.

FALSE

Specifies that TRUNCATING records is not allowed. If it is determined that records are truncated, then set an error, and fail the file transfer. If the option WRAPRECORD TRUE is set, the long records are wrapped, not truncated, and no error is set.

Examples

FTP detects a record longer than LRECL, sets an error of 1 003 and fails the transfer of the file.

```
WRAPRECORD TRUE
TRUNCATE FALSE
```

UCOUNT (FTP client and server) statement

Use the UCOUNT statement to set the unit count for new data set allocations.

Server

This setting applies when creating data sets on the server's system.

Client

This setting applies when creating data sets on the client's system.

Syntax

➤ UCOUNT  *unit-count* ➤

Parameters

unit-count

The unit count to be specified for new data set allocations. Valid values are 1 - 59 (inclusive), or the letter P for parallel mount requests. UCOUNT has no default value. If you do not specify a UCOUNT value, the FTP server does not specify a unit count for new allocations. The unit count used is the system default.

Examples

To specify a unit count of two, use the following code:

```
UCOUNT 2
```

To specify parallel mounts, use the following code:

```
UCOUNT P
```

Usage notes

- The UCOUNT statement should not be used with an SMS storage class. Any UCOUNT value you specify overrides whatever is specified for the SMS managed dataclass being used.
- UCOUNT can be dynamically modified using the SITE and LOCSITE commands. See [z/OS Communications Server: IP User's Guide and Commands](#) for more information about these commands.

Related topics

- See the information about storage management subsystem (SMS) in [z/OS Communications Server: IP Configuration Guide](#) for more information about specifying attributes when allocating new data sets.
- [“STORCLASS \(FTP client and server\) statement” on page 769](#)

UCSHOSTCS (FTP client and server) statement

Use the UCSHOSTCS statement to specify the EBCDIC code set to be used for data conversion to or from Unicode. If the UCSHOSTCS statement is not used, the current code set for FTP host is used.

Syntax

➤ UCSHOSTCS — *code_set* ➤

Parameters

code_set

The EBCDIC code set that is to be used when converting to or from Unicode. See the [z/OS XL C/C++ Programming Guide](#) for the valid EBCDIC code set names.

Examples

To set up for conversion between Unicode and IBM 932, use the following code:

```
UCSHOSTCS IBM-932
```

Related topics

- [“UCSSUB \(FTP client and server\) statement” on page 780](#)
- [“UCSTRUNC \(FTP client and server\) statement” on page 781](#)

UCSSUB (FTP client and server) statement

Use the UCSSUB statement to specify whether Unicode-to-EBCDIC conversion should use the EBCDIC substitution character or cause the data transfer to be terminated if a Unicode character cannot be converted to a character in the target EBCDIC code set.

Syntax

Parameters

TRUE

Specifies that the EBCDIC substitution character is used to replace any Unicode character that cannot successfully be converted. Data transfer continues.

FALSE

Specifies that the data transfer is terminated if any Unicode character cannot be successfully converted.

Examples

To specify that data transfer should be terminated if unicode translation is unsuccessful, use the following code:

```
UCSSUB FALSE
```

Related topics

- [“UCSHOSTCS \(FTP client and server\) statement” on page 780](#)
- [“UCSTRUNC \(FTP client and server\) statement” on page 781](#)

UCSTRUNC (FTP client and server) statement

Use the UCSTRUNC statement to specify whether the transfer of Unicode data should be aborted if truncation occurs at the MVS host. Truncation can occur if the LRECL of the receiving data set is not large enough to contain a line of Unicode data after it has been converted to EBCDIC.

UCSTRUNC applies to inbound data transfers only.

Syntax

Parameters

TRUE

Specifies that truncation is allowed. The data transfer continues even if EBCDIC data is truncated.

FALSE

Specifies that truncation is not allowed. The transfer is to be aborted if the LRECL of the receiving data set is too small to contain the data after conversion to EBCDIC.

Result: The setting of CONDDISP determines what happens to the target data set if the transfer is aborted.

Examples

To specify that truncation is not allowed, use the following code:

```
UCSTRUNC FALSE
```

Related topics

- [“UCSHOSTCS \(FTP client and server\) statement” on page 780](#)
- [“UCSSUB \(FTP client and server\) statement” on page 780](#)

UMASK (FTP client and server) statement

Use the UMASK statement to define the file mode creation mask.

The file mode creation mask defines which permission bits are NOT to be set on when a file is created. When a file is created, the permission bits requested by the file creation are compared to the file mode creation mask, and any bits requested by the file creation that are not allowed by the file mode creation mask are turned off.

Server

This setting applies when creating z/OS UNIX files on the server's system.

Client

This setting applies when creating z/OS UNIX files sets on the client's system.

Syntax

Parameters

octal_umask

The octal umask.

Examples

When a file is created, the permission bits for file creation are 666 (-rw-rw-rw-). If the file mode creation mask is 027, the requested permissions and the file mode creation mask are compared:

```
110110110 - 666
000010111 - 027
-----
110100000 - 640
```

When the UMASK is set to 027, the actual permission bits set for a file when it is created is 640 (-rw-r-----).

Usage notes

You cannot use FTP to create z/OS UNIX files that have execute permissions. If you require execute permissions, use the **site** and **chmod** commands or **locsite chmod** subcommand after the file is created. For more information about **site** and **locsite**, see [z/OS Communications Server: IP User's Guide and Commands](#).

UNICODEFILESYSTEMBOM (FTP client and server) statement

Use the UNICODEFILESYSTEMBOM statement to specify whether to add a byte order mark (BOM) to a file stored in the local file system when the file system code page is Unicode. You can also use the SItE and LOCStE subcommands to set this keyword.

Restriction: UTF-8 and UTF-16 are the only Unicode encodings supported in the file system by z/OS FTP.

Result: The BOM stored with the file is determined by the encoding used to store the file rather than by the format of the BOM sent with the file.

Server

This setting applies when you are storing Unicode data into the server's file system.

Client

This setting applies when you are storing files as Unicode on the client's file system.

Syntax

Parameters

ASIS

If a BOM is present in a Unicode file that is received from the network, store the file with a BOM. If a BOM is not present, store the file without a BOM. The default is ASIS.

ALWAYS

Always include a BOM when storing the file. If the file is received without a BOM, insert a BOM into the file.

NEVER

Never include a BOM when storing a UNICODE file. If the file is received with a BOM, discard it before storing the file.

The UNICODE BOM, U+FEFF, can also be interpreted as *zero width nonbreaking space*. z/OS FTP considers only the first character of the file as a possible BOM. No other instance of the BOM sequence in the file is affected by this setting.

Results:

- When appending to a nonexistent regular z/OS UNIX file or MVS data set, the FTP server abides by the UNICODEFILESYSTEMBOM setting.
- When appending to an existing regular z/OS UNIX file or MVS data set, the FTP server always strips a leading BOM from the incoming file. This prevents a superfluous BOM from being inserted in the middle of the server file.
- When storing or appending to a z/OS UNIX named pipe, the FTP server always applies the UNICODEFILESYSTEMBOM setting. Multiple transfers into the same named pipe can result in multiple BOM byte sequences inserted into the named pipe.

Guidelines:

- The presence or absence of a BOM can affect applications that process UNICODE files. Consult documentation for applications that process your files or data sets.
- Do not use a BOM when storing UNIX system services configuration files.
- Multiple transfers into a z/OS UNIX named pipe can result in multiple BOM byte sequences being inserted into the named pipe when the UNICODEFILESYSTEMBOM value is ASIS or ALWAYS. To prevent superfluous BOM byte sequences from being inserted in a named pipe, consider setting the UNICODEFILESYSTEMBOM value to NEVER after the first transfer into the named pipe.

Examples

To transfer a UTF-8 file to the server, save it in the server file system as UTF-8, and to guarantee the destination file contains a Byte Order Mark, code the following statements in the server's FTP.DATA:

```
ENCODING MBCS
MBDATACONN(UTF-8,UTF-8)
UNICODEFILESYSTEMBOM ALWAYS
```

Related topics

- [“MBDATACONN \(FTP client and server\) statement” on page 705](#)

- [“UNIXFILETYPE \(FTP client and server\) statement” on page 784](#)

UNITNAME (FTP client and server) statement

Use the UNITNAME statement to specify the unit type for allocation of new data sets.

Server

This setting applies when creating data sets on the server's system.

Client

This setting applies when creating data sets on the client's system.

Syntax

➤ UNITNAME 

Parameters

type

The type of either direct access or tape devices.

SYSDA

If *type* is not specified, the unit type used for allocation is the system default.

Examples

- Set the unit type for new data sets to 3380:

```
UNITNAME 3380
```

- Set the unit type for new data sets to TAPE:

```
UNITNAME TAPE
```

Usage notes

- If you do not use the UNITNAME statement to specify the *type*, the unit type used for allocation is the system default unit.
- If the STORCLASS statement is also specified, the SMS storage class might contain settings that override the UNITNAME *type*.
- It is preferable that you do not use the UNITNAME statement if you are using an SMS storage class.
- The UNITNAME can name a dynamic device.

Related topics

- See the information about storage management subsystem (SMS) in [z/OS Communications Server: IP Configuration Guide](#) for more information about specifying attributes when allocating new data sets.
- [“STORCLASS \(FTP client and server\) statement” on page 769](#)

UNIXFILETYPE (FTP client and server) statement

Use the UNIXFILETYPE statement in the FTP server and client to indicate whether to treat z/OS UNIX file system files as regular files or as UNIX named pipes during file transfer. The site and locsite subcommands are also available to set this value.

Server

This setting applies to files in the server's z/OS UNIX file system when the server is processing the APPE, RETR, and STOR commands.

The server ignores this setting when processing the RNFR, RNT0, and DELE. commands. You can use these commands to rename or delete regular files and named pipes regardless of the UNIXFILETYPE setting.

The server accepts the XFIF (create named pipe) command regardless of the UNIXFILETYPE setting.

When the server is processing LIST and NLST commands to list files in the z/OS UNIX file system, both named pipes and regular files appear regardless of the UNIXFILETYPE setting.

Restrictions:

- You cannot restart a file transfer to a named pipe in the server z/OS UNIX file system.
- The server does not support the STOU command when UNIXFILETYPE is set to FIFO.
- Anonymous users are not allowed to read from or write to named pipes in the server z/OS UNIX file system.

Requirements: When the server file exists before it receives the APPE or STOR command, perform the following actions:

- Set UNIXFILETYPE to FILE when the file is a regular file.
- Set UNIXFILETYPE to FIFO when the file is a named pipe.

Client

This setting applies to files in the client's z/OS UNIX file system when the client is processing the following subcommands:

- APpend
- Get
- MGet
- MPut
- PUt

Restriction: You cannot restart a file transfer to a named pipe in the client z/OS UNIX file system.

Syntax

Parameters

FILE

Treat files in the z/OS UNIX file system as regular files for file storage and retrieval. This is the default value.

Result: When FTP stores a file that does not yet exist in the z/OS UNIX file system, FTP stores the file as a regular file.

Requirement: When FTP stores to a file that already exists in the z/OS UNIX file system, the file must be a regular file.

FIFO

Treat files stored in the z/OS UNIX file system as named pipes for file storage and retrieval.

Result:

- When storing a file that does not yet exist in the z/OS UNIX file system, FTP stores the file as a named pipe.
- When storing to a named pipe that already exists in the z/OS UNIX file system, FTP appends the incoming data to the existing data. This is true for both the APPE (append) and STOR (store) commands.

Requirement: When storing to a file that already exists in the z/OS UNIX file system, the file must be a named pipe.

Restrictions:

- You can append only to existing named pipes.
- You cannot restart a transfer into a named pipe.
- The z/OS operating system does not serialize access to named pipes. Multiple processes can read from or write to the same named pipe simultaneously. When a process reads from a named pipe, data is removed from the named pipe. That data is not presented to other processes that read from the same named pipe. When a process writes to a named pipe, the data it writes might appear in the named pipe interleaved with data written by other processes.

Examples

To treat the files in the z/OS UNIX file system as UNIX named pipes for file transfer, use the following code:

```
UNIXFILETYPE FIFO
```

Related topics

- [“FIFOOPENTIME \(FTP client and server\) statement” on page 685](#)
- [“FIFOIOTIME \(FTP client and server\) statement” on page 684](#)

VCOUNT (FTP client and server) statement

Use the VCOUNT statement to set the volume count for new data set allocations when writing to tapes.

Server

This setting applies when creating data sets on the server's system.

Client

This setting applies when creating data sets on the client's system.

Syntax

Parameters

volume-count

Valid values are integers from 1 - 255 (inclusive). The default value is 59.

Examples

To allow multiple volumes for data set allocation, use the following code:

VCOUNT 2
VOLUME (WRKLB1,WRKLB2)

Usage notes

- VCOUNT can be dynamically modified using the SITE and LOCSITE commands. See [z/OS Communications Server: IP User's Guide and Commands](#) for more information about these commands.

Related topics

- See the information about storage management subsystem (SMS) in [z/OS Communications Server: IP Configuration Guide](#) for more information about specifying attributes when allocating new data sets.
- “STORCLASS (FTP client and server) statement” on page 769
- “VOLUME (FTP client and server) statement” on page 788

VERIFYUSER (FTP server) statement

Use the VERIFYUSER statement to indicate whether the FTP server should verify that every user ID used to log into FTP has been granted access to the server's port profile in the SERVERAUTH class.

Tips:

- The FTP server port profile is the same profile that is checked for TLS secured sessions when SECURE_LOGIN VERIFY_USER is coded in FTP.DATA. See [“SECURE_LOGIN \(FTP server\) statement” on page 743](#) for more information.
- When sessions are secured with TLS and VERIFYUSER TRUE is coded in FTP.DATA, the server verifies the user access to the FTP server port profile regardless of the SECURE_LOGIN value.

Syntax

Parameters

TRUE

If the SERVAUTH class is active and a profile has been defined for the FTP port, the connection is allowed only if the user ID has a minimum of READ access to the profile.

The resource name is as follows:

```
EZB.FTP.systemname.ftpddaemonname.PORTxxxxx
```

xxxxx is replaced by the port number for the FTP daemon. The profile name can contain wildcard values to the extent that the security product allows. All security product rules apply.

For example, if the procedure FTPD is used to start the FTP daemon on system MVS164 and the FTP daemon uses the default FTP port 21, the resource name is:

```
EZB.FTP.MVS164.FTPD1.PORT21
```

To protect all ports with a single profile, you could use the following security product profile name:

```
EZB.FTP.*.FTPD1.PORT*
```

Result: If the VERIFYUSER value is TRUE, but the security product profile is not defined, the FTP server does not verify access to the profile prior to allowing users to log into FTP.

FALSE

The server does not verify access to the profile EZB.FTP.*systemname.ftpddaemonname*.PORTxxxxx before allowing the login.

Restriction: If the session is secured with TLS and SECURE_LOGIN VERIFY_USER is coded in FTP.DATA, the server checks the user's access to the profile as described in [“SECURE_LOGIN \(FTP server\) statement” on page 743](#) regardless of the VERIFYUSER setting.

Examples

To request that the FTP server verify user access to the SERVAUTH profile for all sessions regardless of whether they are secured with TLS and regardless of whether TLS level 3 authentication is requested, code this statement in FTP.DATA:

```
VERIFYUSER TRUE
```

You should also define the port profile of the server in the SERVAUTH class of your security product.

For example, if the FTPD procedure is used to start the FTP daemon on system MVS164, and the FTP daemon uses the default FTP port 21, the resource name is as follows:

```
EZB.FTP.MVS164.FTPD1.PORT21
```

If all systems use the same access list and generic profile checking is active for the SERVAUTH class, you can use the following profile name:

```
EZB.FTP.*.FTPD1.PORT21
```

To protect all ports with a single profile, you can use the following security product profile name:

```
EZB.FTP.*.FTPD1.PORT*
```

Related topic

- [“SECURE_LOGIN \(FTP server\) statement” on page 743](#)

VOLUME (FTP client and server) statement

Use the VOLUME statement to specify the volume serial number or a list of volume serial numbers for allocation of new data sets.

Server

This setting applies when creating data sets on the server's system.

Client

This setting applies when creating data sets on the client's system.

Syntax

➔ VOLUME ——— name ———➔
 └── (serial-list) ─┘

Parameters

name

The volume serial number.

(*serial-list*)

A list of volume serial numbers for new data set allocations.

Examples

Use two volumes for new data set allocations:

```
VOLUME (WRKLB2,WRKLB4)
```

Usage notes

- If you do not use the VOLUME statement to specify the *name*, the volume serial number used for allocation is the system default volume list.
- If the STORCLASS statement is also specified, the SMS storage class might contain settings that override the VOLUME *name*.
- It is preferable that you do not use the VOLUME statement if you are using an SMS storage class.
- When transferring a variable-length file to multiple volumes on MVS, only the last file contains the correct DCB characteristics.
- If you specify multiple volumes, specify them in the order you prefer them to be allocated.

Related topics

- See storage management subsystem (SMS) information in [z/OS Communications Server: IP Configuration Guide](#) for more information about specifying attributes when allocating new data sets.

WRAPRECORD (FTP client and server) statement

Use the WRAPRECORD statement to specify how the FTP server or client treats an incoming data record longer than the logical record in which it is to be stored.

Server

This setting applies when transferring data sets to the server's system.

Client

This setting applies when transferring data sets to the client's system.

Syntax

Parameters

TRUE

Indicates that data is wrapped to the next record if no new-line character is encountered before the logical record length is reached.

FALSE

Indicates that data is truncated if no new-line character is encountered before the logical record length is reached. This is the default. If TRUNCATE is also set to FALSE, an error is set and the file transfer fails.

Examples

Truncate data if no new-line character is encountered before the logical record length is reached:

```
WRAPRECORD FALSE
```

Results

If WRAPRECORD is specified and the data is multibyte characters, it is possible that wrapping will occur in the middle of a multibyte character, making the data unusable by some applications.

WRTAPEFASTIO (FTP client and server) statement

Use the WRTAPEFASTIO statement to specify whether a write to tape of ASCII data in Stream mode can use the BSAM I/O routine instead of the Language Environment Run-Time Library function *fwrite()*.

Server

This setting applies when transferring files to the server's system.

Client

This setting applies when transferring files to the client's system.

Syntax

Parameters

TRUE

Indicates that a write to tape of ASCII data in Stream mode is allowed to use the BSAM I/O routine instead of the Language Environment Run-Time Library *fwrite()* function. This allows the data set to be processed without embedded hexadecimal values being interpreted as print control characters.

FALSE

Indicates that a write to tape of ASCII data in Stream mode must use the Language Environment Run-Time Library *fwrite()* function. This is the default and is used to take advantage of the features of the Language Environment Run-Time Library.

Examples

Allow ASCII Stream data to be written to tape using the BSAM I/O routine:

```
WRTAPEFASTIO TRUE
```

Require ASCII Stream data be written to tape using the Language Environment Run-Time Library:

```
WRTAPEFASTIO FALSE
```

XLATE (FTP server) statement

Use the XLATE statement to specify a data set containing translate tables to be used for the data connection.

Syntax

➤ XLATE — *name* ➤

Parameters

name

Specifies a 1- to 8-character name corresponding to a data set that contains translate tables.

FTP looks first for an environment variable called `_FTPXLATE_name`. If the environment variable exists, its value is used as the data set name.

Restriction: The environment variable name must be all uppercase, although the XLATE parameter can be in mixed case.

If the environment variable does not exist, FTP looks for a data set called *hlq.name*.TCPXLBIN.

Examples

```
XLATE FRED
```

If environment variable `_FTPXLATE_FRED=FREDDYS.TABLES` is defined for the FTP server, this statement specifies that the translate tables in data set FREDDYS.TABLES should be used for the data connection.

If there is no such environment variable defined, this statement specifies that the translate tables data set *hlq.FRED*.TCPXLBIN should be used.

Usage notes

- SBADATACONN and XLATE are mutually exclusive statements. If both statements appear in your FTP.DATA file, XLATE is ignored.
- The XLATE statement (and its value) is not case sensitive, but the name of the corresponding environment variable must be all uppercase or FTP does not recognize it.

Related topics

FTP server environment variables

Table 51 on page 792 provides a list of environment variables used by FTP server that can be tailored to a particular installation.

Table 51. FTP server environment variables			
Environment variable	Server, Client or Command-type application	Description	Any specific coding rules (or a link to syntax)
_ICONV_UCS2	FTP	Instructs iconv_open(Y, X) about which type of conversion method to set up when there is a choice between direct conversion from X to Y and indirect X to UCS-2 to Y.	This environment variable has no affect on streams that are based on z/OS UNIX files. You can always read and write 0-byte records in z/OS UNIX files.
RESOLVER_CONFIG	FTP	The resolver configuration data sets or files.	None

SOCKS configuration statements in SOCKSCONFIGFILE

The FTP client uses configuration information in a SOCKS configuration data set or file to determine whether to access a given IPv4 FTP server directly or through a SOCKS server. The name of the SOCKS configuration data set or file is specified by coding the SOCKSCONFIGFILE statement in the client's FTP.DATA file. For more information about the SOCKSCONFIGFILE statement, see [“SOCKSCONFIGFILE \(FTP client\) statement”](#) on page 764.

You can code DIRECT or SOCKD statements in the SOCKSCONFIGFILE. A DIRECT statement instructs the FTP client to access the FTP server without using SOCKS. A SOCKD statement directs the client to use SOCKS protocols and the specified SOCKS server to access the FTP server.

You can include comments in the configuration file or data set. Comment lines should start with a semicolon (;) character. Any data on any line that follows a free-standing semicolon (a semicolon surrounded by at least one space on either side) is considered to be a comment.

The order of statements in the SOCKS configuration is important. The client searches the statements in the order they are coded in the SOCKSCONFIGFILE. The first statement that specifies the target FTP server is applied. Code statements that apply to specific FTP servers first, and a general statement for all other servers last.

The configuration information in the SOCKS configuration file consists of the statements in the following topics.

DIRECT statement

Use the DIRECT statement to instruct the FTP client not to use SOCKS for the destinations that are included in the DIRECT statement.

Syntax

```

➤➤ DIRECT  ┌ IPv4_address address_mask ──➤➤
            └ IPv4_address/num_mask_bits ──➤➤

```

Parameters

direct

Access the FTP server indicated by this statement without using SOCKS protocols.

IPv4_address

Dotted decimal IPv4 address of the FTP server host, or the dotted decimal IPv4 Network ID of the FTP server network or subnet. The network ID can include subnet bits.

address_mask

Dotted decimal IPv4 subnet mask.

num_mask_bits

An integer in the range 1 - 32 that represents the number of bits, counting from left to right, of the network and subnet portion of the IPv4 address mask.

Examples

The following statements instruct the FTP client not to use SOCKS for connections to any FTP servers in the class A 9.0.0.0 network, nor to connections to the host's loopback address.

```
;
; This is my socks configuration
;
direct 9.0.0.0 255.0.0.0           ; Internal net
direct 127.0.0.1 255.255.255.255 ; Loopback
```

The following statement directs the FTP server not to use SOCKS for connections to the host's loopback address (num_mask_bits is coded instead of address_mask).

```
;
; This is my socks configuration
;
direct 127.0.0.1/32              ; Loopback
```

Usage notes

- You can code as many DIRECT statements as needed to cover your configuration.
- The FTP client always acts as if the statement `direct 0.0.0.0 0.0.0.0` were coded last in the SOCKSCONFIGFILE. This statement applies to every possible FTP server and directs the client not to use SOCKS to access any server not covered by a previous statement. Therefore, the client connects to any FTP server for which no statement has been coded in SOCKSCONFIGFILE without using SOCKS. Also, note that if you code this statement in the SOCKSCONFIGFILE explicitly, any statements you coded after that would be ignored because the client always uses the first statement that applies to the FTP server.

SOCKD statement

Use the SOCKD statement to instruct the FTP client to use a SOCKS server for the destinations that are included in the sockd statement.

Syntax

Parameters

SOCKD

The SOCKS server requires the use of SOCKSv5 protocols.

SOCKD4

The SOCKS server requires the use of SOCKSv4 protocols.

SOCKD5

The SOCKS server requires the use of SOCKSv5 protocols.

SOCKS_srv_host_name

The DNS name of the SOCKS server host.

SOCKS_srv_IPv4_addr

The dotted decimal IPv4 IP address of the SOCKS server host.

IPv4_address

Dotted decimal IPv4 address of the FTP server host, or the dotted decimal IPv4 Network ID of the FTP server network or subnet. The network ID can include subnet bits.

IPv4_address_mask

Dotted decimal IPv4 subnet mask.

num_mask_bits

An integer between 1 and 32 that represents the number of bits, counting from left to right, of the network and subnet portion of the IPv4 address mask.

Examples

In the following example, the first statement instructs the client to use SOCKS V4 protocols and the SOCKSv4 server at IP address 9.1.2.3 for connections to FTP servers within the class C 192.168.1.0 network. The second statement instructs the client to use SOCKSv5 protocols and the SOCKSv5 server at IP address 9.1.2.4 to access any FTP server not covered by a previous statement.

```
sockd4 @=9.1.2.3 192.168.1.0 255.255.255.0 ; Test net
sockd5 @=9.1.2.4 0.0.0.0 0.0.0.0 ; Anything else
```

Usage notes

- You can code as many SOCKD statements as needed to cover your configuration.
- DIRECT and SOCKD statements can be mixed in any order.

Chapter 15. Syslog daemon

This topic contains the following information:

- [“Syslog daemon files” on page 795](#)
- [“Starting syslogd with a cataloged procedure” on page 795](#)
- [“Starting syslogd from the UNIX shell” on page 797](#)
- [“Syslogd environment variables” on page 800](#)
- [“Syslogd configuration statements” on page 802](#)
- [“Syslogd browser tool” on page 815](#)

Syslog daemon files

The syslog daemon (syslogd) uses the following files:

/dev/console

Operator console

/dev/operlog

operlog log stream

/etc/syslog.pid

The syslogd cataloged procedure stores its process ID in this file when running in normal or local-only mode

/etc/syslog_net.pid

syslogd stores its process ID in this file when running in the network-only mode

/etc/syslog.conf

Default configuration file

/dev/log

Default log path for UNIX datagram socket

/usr/sbin/syslogd

Symbolic link to the server executable

Starting syslogd with a cataloged procedure

Update the cataloged procedure, syslogd, by copying the sample in SEZAINST(SYSLOGD) to your system or recognized PROCLIB. Specify syslogd parameters and change the data set names to suit your local configuration. See the syslog daemon section of SEZAINST(EZARACF) for SAF considerations for started procedures. When you start syslogd from a procedure that does not use BPXBATCH, the resulting job name is the same as the procedure name. When you start syslogd from the z/OS UNIX shell or from a procedure that uses BPXBATCH, the resulting job name is the user ID or the value of the _BPX_JOBNAME environment variable.

See [“Starting syslogd from the UNIX shell” on page 797](#) for the syntax of the start options for syslogd.

Below is a copy of the sample procedure:

```
//SYSLOGD PROC
//*****
//*      Descriptive Name:          SYSLOGD Start Procedure      *
//*      *      *      *      *      *      *      *      *      *
//*      File Name:                tcpip.SEZAINST(EZASYSLG)      *
//*      *      *      *      *      *      *      *      *      *
//*      *      *      *      *      *      *      *      *      *
//*      SMP/E Distribution Name:   EZASYSLG                     *
//*      *      *      *      *      *      *      *      *      *
//*      Licensed Materials - Property of IBM                    *
```

```

/**      "Restricted Materials of IBM"
/**      5650-ZOS
/**      Copyright IBM Corp. 1992, 2023
/**      Status = ZCSV2R5
/**
/** Note:
/** The SYSLOGD Daemon can read its configuration file from either a
/** PDS or the HFS. The procedure defaults to the HFS.
/** If you are running the IVP for SYSLOGD or if you simply prefer
/** to use a PDS to store your configuration file,
/** either delete or comment the CONFHFS DD card
/** then uncomment the CONFPDS DD card and specify the data set and
/** member name.
/**
/** If you would like to run two instances of syslogd, make a second
/** copy of this proc and replace -i with -n in the second instance.
/** The instance using -n will process only log messages received
/** over the network. One instance must use -i and the other must
/** use -n in order to run two instances.
/**
/** The -c command-line option specifies that syslogd should create
/** any log files or directories which do not already exist.
/**
/** The -i command-line option specifies that syslogd should not
/** process log messages received over the network.
/**
/*******
/**CONFHFS EXEC PGM=SYSLOGD,REGION=0M,TIME=NOLIMIT,
/**      PARM='ENVAR("_CEE_ENVFILE_S=DD:STDENV")/-c -i'
/**
/***** Examples for specifying environment variables and parameters
/***** (parameters must extend to column 71 and be continued in
/***** column 16):
/**
/**      Example 1: Environment variables inline, MVS config data set
/**
/**CONFPDS EXEC PGM=SYSLOGD,REGION=0M,TIME=NOLIMIT,
/**      PARM='ENVAR("TZ=EST5EDT")/-c -i -f //'TCPIP.TCPPARMS(SYSLOG
/**      )'''
/**
/**      Example 2: Environment variables inline, UNIX config file
/**
/**CONFHFS EXEC PGM=SYSLOGD,REGION=0M,TIME=NOLIMIT,
/**      PARM='ENVAR("TZ=EST5EDT")/-c -i -f /user1/syslogd.conf'
/**
/**      Example 3: Environment variables in STDENV DD
/**
/**CONFSTD EXEC PGM=SYSLOGD,REGION=0M,TIME=NOLIMIT,
/**      PARM='ENVAR("_CEE_ENVFILE_S=DD:STDENV")/-c -i'
/**
/**      For this method, the STDENV DD statement below must be
/**      changed to point to a MVS data set or UNIX file containing
/**      settings for any environment variables. For example, it should
/**      contain at least TZ (unless you choose to specify TZ in a
/**      different fashion), but can contain other environment variables
/**      as in this example:
/**
/**      SYSLOGD_CODEPAGE=IBM-1047
/**      SYSLOGD_CONFIG_FILE=/user1/syslogd2.conf
/**      SYSLOGD_DEBUG_LEVEL=127
/**      TZ=EST5EDT
/**
/**      If you want to include comments in the data set or
/**      z/OS UNIX file, specify the _CEE_ENVFILE_COMMENT
/**      environment variable as the first environment variable
/**      in the data set or file. The value specified for
/**      the _CEE_ENVFILE_COMMENT variable is the comment character.
/**      For example, if you want to use the pound sign, #, as
/**      the comment character, specify this as the first
/**      statement:
/**      _CEE_ENVFILE_COMMENT=#
/**
/**      The use of the STDENV DD statement works well when more than
/**      one environment variable is specified, as there is a JCL limit
/**      of 100 characters on the PARM statement.
/**
/**      Note: Language Environment recommends a variable record format
/**      for the STDENV file.
/**
/**      You can also set the TZ environment variable for all applications
/**      in the CEEPRMxx PARMLIB member. You should define the TZ
/**      environment variable for all three LE option sets (CEEDOPT,
/**      CEECOPT, and CELQDOPT). For example:

```

```

/*
/* CEECOPT(ALL31(ON), ENVAR('TZ=EST5EDT')) )
/* CEEDOPT(ALL31(ON), ENVAR('TZ=EST5EDT')) )
/* CELQDOPT(ALL31(ON), ENVAR('TZ=EST5EDT')) )
/*
/* For more information on specifying run-time options, see z/OS
/* Language Environment Programming Guide. For details on setting
/* the LIBPATH and TZ environment variables, see z/OS UNIX System
/* Services Command Reference.
/*
//STDENV DD DUMMY
/* Sample MVS data set containing environment variables:
/*STDENV DD DSN=TCPIP.SYSLOGD.ENV(SYSLOGD),DISP=SHR
/* Sample UNIX file containing environment variables:
/*STDENV DD PATH='/etc/syslogd.env',PATHOPTS=(ORDONLY)
//SYSPRINT DD SYSOUT=*
//SYSIN DD DUMMY
//SYSERR DD SYSOUT=*
//SYSOUT DD SYSOUT=*
//CEEDUMP DD SYSOUT=*

```

Figure 23. Syslogd sample cataloged procedure

Starting syslogd from the UNIX shell

Start syslogd from the UNIX shell using the syntax described in this topic.

syslogd [-D *value*][-F *value*][-f *conffile*] [-m *markinterval*] [-p *logpath*] [-c] [-d] [-i] [-n][-x][-u] [-S][-T][-U] [-?]&

Rules:

- You must start syslogd as a background shell command by specifying an ampersand (&) as the last character on the command. If you do not specify the ampersand (&), control does not return to the shell until syslogd ends. This is especially important if syslogd is started from a shell script, such as `/etc/rc`.
- If you start syslogd from a cataloged procedure that uses BPXBATCH, you need to include a sleep command in your script after you start syslogd. The sleep command gives syslogd time to initialize before the shell script ends. For more information about including a sleep command, see [Starting daemons in z/OS UNIX System Services Planning](#).
- If you start syslogd from a cataloged procedure that uses BPXBATCH, you need to use a z/OS UNIX file for the STDOUT DD JCL statement and the STDERR DD JCL statement; otherwise, the job will not end.

syslogd recognizes the following options:

-c

Create log files and directories automatically. The -c option is required to use the automatic archive function. For more information, see [Configuring syslogd for automatic archiving in z/OS Communications Server: IP Configuration Guide](#).

-d

Run syslogd in debugging mode. For more information, see [Diagnosing syslogd configuration problems in z/OS Communications Server: IP Configuration Guide](#).

-D

Specify the default access permissions (modes) to be used by syslogd when creating directories. This parameter is valid only when specified in conjunction with the -c option. The parameter value is specified as an octal number 1 - 4 characters in length. Leading zeros can be omitted. The following values can be ORed together to form the parameter value:

2000

Set-GID

1000

Sticky Bit (deletion restricted to owner or superuser)

0400

User read

0200

User write

0100

User list directory

0040

Group read

0020

Group write

0010

Group list directory

0004

Other read

0002

Other write

0001

Other list directory

If the -D option is not specified, the default value 700 is used. The actual permissions are modified by the syslogd process umask value at the time when the file is created. Value 0000 is not valid. Bits other than the bits shown are not valid and are set to 0. For example, you cannot set the set-UID bit for a directory. z/OS does not use the set-GID bit during directory creation regardless of whether the bit was set in the directory permissions.

-f

Configuration file name. You can also specify the configuration file using the SYSLOGD_CONFIG_FILE environment variable. The -f option overrides the environment variable.

-F

Specify the default access permissions (modes) to be used by syslogd when creating log files. This parameter is valid only when specified in conjunction with the -c option. The parameter value is specified as an octal number 1 - 4 characters in length. Leading zeros can be omitted. The following values can be ORed together to form the parameter value:

0400

User read

0200

User write

0040

Group read

0020

Group write

0004

Other read

0002

Other write

If the -F option is not specified, the default value 600 is used. The actual permissions are modified by the syslogd process's umask value at the time the file is created. This parameter is used only when syslogd must create a log file dynamically; it has no effect on log files that already exist. Value 0000 is not valid. Bits other than the bits shown are not valid and are set to 0. For example, you cannot set the execute bits, set-UID, set-GID, or the sticky bit for log files.

-i

Start in local-only mode. Do not receive messages from the IP network. Messages can be sent by syslogd to remote syslogd instances when running in local-only mode.

This option is mutually exclusive with the -n option. If syslogd is started with the -i option, another instance of syslogd can be started with the -n option. This is the only supported way to run two instances of syslogd on the same z/OS image.

-m

Number of minutes between mark messages. The default value is 20 minutes. The following rule must be coded for each logfile that you want a mark record recorded in: mark.info.

-n

Start in network-only mode. Process messages from the IP network only. Messages can be written locally or sent by syslogd to remote syslogd instances when running in network-only mode.

This option is mutually exclusive with the -i option. If syslogd is started with the -n option, another instance of syslogd can be started with the -i option. This is the only supported way to run two instances of syslogd on the same z/OS image.

-p

Pathname of z/OS UNIX character device for the datagram socket. The default value is /dev/log. You can also specify the path name using the SYSLOGD_PATH_NAME environment variable. The -p option overrides the environment variable.

Guideline: This option is not used frequently. If you use the -p option incorrectly, syslogd does not function properly.

-S

Allow messages to be received over the network using TCP connections with TLS protection. The TCP port identified for use with the syslog-tls tcp service (or default port 6514) is opened. The syslog-tls tcp service is defined in your services file or data set (for example, /etc/services).

This option is mutually exclusive with the -i option.

-T

Allow messages to be received over the network using TCP connections without TLS protection. The TCP port identified for use with the syslog tcp service (or default port 514) is opened. The syslog tcp service is defined in your services file or data set (for example, /etc/services).

This option is mutually exclusive with the -i option.

-U

Allow messages to be received over the network using the UDP port identified for use with the syslog udp service (or default port 514). The syslog udp service is defined in your services file or data set (for example, /etc/services).

This option is mutually exclusive with the -i option.

Note: The same UDP socket is used to both receive and send syslogd messages. The port can be open to send messages, but messages can only be received from the network if syslogd was started in normal or network-only mode and one of the following is true:

- -U is specified or
- -T, -S, and -U are not specified

-u

For records received over the AF_UNIX socket (most messages generated on the local system), include the user ID and job name in the record. In this case, a forward slash (/), the user ID, and the job name follows the local host name for messages received over the AF_UNIX socket. The forward slash, which immediately follows the local host name, can be used to determine whether or not the user ID and job name are being recorded. If not recorded, a blank immediately follows the local host name. When user ID or job name is not available, N/A is written in the corresponding field.

-x

Do not perform IP address-to-host name resolution for messages received from the IP network.

This option is mutually exclusive with the -i option. Using this option can improve the performance of syslogd when processing messages received from the IP network. It has no effect for local messages. When you use this option, the IP address (instead of the host name) of the origin host is logged, along

with the message text. If the host name can be determined from the rule without having to make a resolver call, the host name is used instead of the IP address. When the -x option is not used, syslogd always attempts to resolve the host name associated with a log message arriving from the IP network. If the host name cannot be determined, the IP address is logged as the message origin instead of the host name.

-?

Show syslogd command-line options.

Syslogd environment variables

Table 52 on page 800 provides a list of environment variables used by syslogd that can be tailored to a particular installation.

Table 52. Syslogd environment variables		
Environment variable	Description	Specific coding rules
SYSLOGD_CODEPAGE	Used by the syslog daemon to specify the EBCDIC code page to be used for the configuration file. The default code page is IBM-1047.	<p>The following code pages are supported:</p> <ul style="list-style-type: none"> • IBM-037 • IBM-273 • IBM-274 • IBM-275 • IBM-277 • IBM-278 • IBM-280 • IBM-281 • IBM-282 • IBM-284 • IBM-285 • IBM-297 • IBM-500 • IBM-871 • IBM-1047 • IBM-1140 • IBM-1141 • IBM-1142 • IBM-1143 • IBM-1144 • IBM-1145 • IBM-1146 • IBM-1147 • IBM-1148 • IBM-1149 <p>Example:</p> <pre>SYSLOGD_CODEPAGE=IBM-1141</pre>
SYSLOGD_CONFIG_FILE	Specifies the name of the syslogd configuration file.	<p>The -f start option overrides this value. Example:</p> <pre>SYSLOGD_CONFIG_FILE=/etc/syslog.conf</pre>

Table 52. Syslogd environment variables (continued)		
Environment variable	Description	Specific coding rules
SYSLOGD_DEBUG_DATASET	If this environment variable is not set, the debug output goes to STDOUT. The environment variable can be set to STDOUT, which will also cause the output to be written to STDOUT. On SYSLOGD shutdown, the SYSLOGD_DEBUG_VARIABLE is reset, which causes residual debug output to be written to STDOUT.	<p>Write debug output to an MVS dataset</p> <pre>SYSLOGD_DEBUG_DATASET=// 'USER1.SYSLOGD.DEBUG'</pre> <p>Write debug output to a UNIX file</p> <pre>SYSLOGD_DEBUG_DATASET=/tmp/syslogd_debug</pre>
SYSLOGD_DEBUG_LEVEL	Specifies the debug level to be used by syslogd.	<p>You can specify the following debug levels. You can add these together in any combination to select the type of debug messages to be written.</p> <p>1 Base debugging information.</p> <p>2 Configuration file processing.</p> <p>4 Processing of messages being logged by syslogd.</p> <p>8 Automatic archive processing.</p> <p>16 Operator command processing.</p> <p>32 Thread-specific processing.</p> <p>64 Mutex lock processing. Locks that are specific to threads are logged only if the debug level includes 32.</p> <p>For example, SYSLOGD_DEBUG_LEVEL=91 includes all debugging information except for message handling and thread-specific processing (including locks). The default debug level is 127, which includes all debug information.</p>
SYSLOGD_PATH_NAME	Specifies the path name of the z/OS UNIX character device for the datagram socket.	The -p start option overrides this value. The default value is /dev/log.
SYSLOGD_TCPTHREADPOOL_SIZE	Specifies the number of threads allocated for inbound TCP connections from remote syslogd clients	<p>By default, 128 threads are allocated for incoming TCP connections. If a small number of remote systems are expected to connect and send messages to this syslogd instance, you can use this environment variable to limit the number of threads allocated for TCP connections.</p> <p>You can specify a value from 5-128.</p>

- When starting syslogd from a shell script, export the environment variables before starting syslogd. The following example defines the syslogd configuration file:

```
#
# Shell script to start syslogd
#
export BPX_JOBNAME='SYSLOGD1'
export SYSLOGD_CONFIG_FILE="//'HLQ.SYSLOGD.CONFIG(DEFAULT)'"
/usr/sbin/syslogd &
```

- When starting syslogd directly from a started procedure, place the syslogd environment variables in a z/OS UNIX file or MVS data set. Use the following technique to pass the environment variables to syslogd.

```
// PARM='ENVAR("_CEE_ENVFILE=DD:STDENV")/'
//STDENV DD PATH='/etc/syslogd.env',PATHOPTS=(ORDONLY)
OR
```

```
//STDENV DD DSN=HLQ.SYSLOGD.ENV(DEFAULT),DISP=SHR
```

When you use an MVS data set for your syslogd environment variables, place the environment variables in a data set with the VB record format [RECFM(VB)] and a logical record length of 256 [LRECL(256)]. If you use any other record format for the data set, use the _CEE_ENVFILE_S environment variable in place of the _CEE_ENVFILE environment variable in your syslogd started procedure. When the _CEE_ENVFILE_S environment variable is used, the system removes trailing blank spaces from each *NAME=VALUE* line that is read. For additional information about the _CEE_ENVFILE_S environment variable, see [z/OS XL C/C++ Programming Guide](#).

Syslogd configuration statements

There are two types of configuration information. The first type is a set of global parameters that you use to configure some operational aspects of syslogd. The second type is a set of rules that you use to define the mapping between the information that is logged to syslogd and the destination of that information.

A sample configuration file is included in /usr/lpp/tcpip/samples/syslog.conf.

Global syslogd configuration statements

This topic contains descriptions of the global syslogd configuration statements.

ArchiveCheckInterval statement

Use the ArchiveCheckInterval statement to specify the interval of time at which syslogd checks UNIX file system utilization. Each configured rule that specifies a UNIX file as the destination and that specifies the -N parameter to indicate that it is eligible for archive processing is a candidate for automatic archival. If you also configure the ArchiveThreshold statement with a nonzero value, the set of UNIX file systems that contain the candidate UNIX files is checked for the percentage used to determine whether threshold archiving needs to be performed.

If the ArchiveCheckInterval statement is specified multiple times, syslogd uses the last instance of the statement.

►► ArchiveCheckInterval — *minutes* ►►

minutes

Specifies the interval at which syslogd checks file system utilization, in minutes. Valid values range 1 - 1 440. If you do not specify this statement, the default is 10 minutes.

ArchiveThreshold statement

Use the ArchiveThreshold statement to specify a percentage of UNIX file system utilization. Each configured rule that specifies a UNIX file as the destination and that specifies the -N parameter to indicate that it is eligible for archive processing is a candidate for automatic archival. When you specify this statement with a nonzero value, each UNIX file system that contains one or more candidate UNIX files is checked at the interval that is configured or the default value to determine the percentage of the file system being used. If the percentage of file use exceeds the specified threshold, syslogd automatically archives a set of UNIX files until the percentage of file use is below the minimum threshold. The minimum threshold is 50 percent of the value that you configure on this statement. For example, if you specify an archive threshold of 80 percent, syslogd archives UNIX files until the percentage of file use is below 40 percent. Syslogd archives files from the largest to the smallest.

If the ArchiveThreshold statement is specified multiple times, syslogd uses the last instance of the statement.

You can use this statement to perform archiving when one or more file systems reach a configured threshold, or you can use the ArchiveTimeOfDay statement to perform archiving at a specific time of day. You can also specify both statements.

Requirement: The -c start option is required when you use the ArchiveThreshold statement.

➤ ArchiveThreshold — *percentage* ➤

percentage

Specifies the percentage value of UNIX file system use that triggers automatic archival. Valid values for *percentage* are in the range 0 - 99. If you do not specify this statement, the default is 70. If you specify 0, syslogd does not perform automatic threshold archiving.

ArchiveTimeOfDay statement

Use the ArchiveTimeOfDay statement to specify a local time of day to perform an archive of all eligible UNIX files. Each configured rule that specifies a UNIX file as the destination and that specifies the -N parameter to indicate that it is eligible for archive processing is a candidate for automatic archival.

You can use this statement to perform archiving at a specific local time of day, or you can use the ArchiveThreshold statement to perform archiving when one or more file systems reaches a configured threshold. You can also specify both statements.

If the ArchiveTimeOfDay statement is specified multiple times, syslogd uses the last instance of the statement.

Requirement: The -c start option is required when you use the ArchiveTimeOfDay statement.

➤ ArchiveTimeOfDay — *time* ➤

time

Specifies the local time of day to perform an automatic archival of all UNIX files. Specify the local time value in hours and minutes, using a 24 hour clock. For example, the value 00:01 means to archive at 1 minute past midnight. There is no default; if you do not specify this statement, syslogd does not perform automatic time of day archival.

BeginArchiveParms statement

Use the BeginArchiveParms statement to specify the prefix and allocation information for the archive destination data set. UNIX files are archived only to MVS data sets when the automatic archive function is used. The complete archive data set name is composed of several components, depending on the type of destination data set that is being used. Use the -N parameter on a specific syslogd rule to specify the type of destination data set.

You should use this method of archiving files only if you do not offload files using the provided sample configuration and procedure. See [z/OS Communications Server: IP Configuration Guide](#) for more information about offloading log files. Because both of these methods rely on creating new log files, results could be unpredictable if you try to use both methods together.

When the destination is a Generation Data Group (GDG) data set, the complete data set name is:

prefix.qualifier.gdg_suffix where:

- *prefix* is the value specified on the BeginArchiveParms statement.
- *qualifier* is the value specified on the -N parameter on a specific syslogd rule.
- *gdg_suffix* is the value automatically supplied for GDG data sets to make them unique.

The following example shows a GDG data set name:

```
USER1.SYSARCH.TRACE.G0007V00
```

When the destination is a sequential data set, the complete data set name is:

prefix.qualifier.date_suffix.time_suffix where:

- *prefix* is the value specified on the BeginArchiveParms statement.

- *qualifier* is the value specified on the -N parameter on a specific syslogd rule.
- *date_suffix* is the date value automatically supplied by syslogd for sequential data sets to make them unique. The format of this suffix is *Dyymmdd*.
- *time_suffix* is the time of day value automatically supplied by syslogd for sequential data sets to make them unique. The format of this suffix is *Thhmmss*.

The following example shows a sequential data set name:

```
USER1.SYSARCH.LOG.D080701.T081342
```

You can repeat this statement multiple times. Each specified statement applies to the rules that follow it, until another instance of this statement is specified. Each statement completely replaces the values from a previous statement. The following sample shows a syslogd configuration file:

```
BeginArchiveParms
  DSNPrefix      USER1.SYSTRACE
  Unit           SYSDA
EndArchiveParms
ArchiveThreshold 80

daemon.debug     /var/syslog/logs/daemon.trace -N DAEMON(+1)
local1.debug     /var/syslog/logs/local1.trace -N LOCAL1(+1)

BeginArchiveParms
  DSNPrefix      USER1.SYSLOG
  Unit           SYSDA
EndArchiveParms

*.*;daemon.none  /var/syslog/logs/syslog.log   -N LOG
```

Given this configuration, the target archive data set names for the configured rules are as follows:

- USER1.SYSTRACE.DAEMON.GnnnnVnn
- USER1.SYSTRACE.LOCAL1.GnnnnVnn
- USER1.SYSLOG.LOG.Dyymmdd.Thhmmss

►► BeginArchiveParms — Put Archive Parameters on Separate Lines — EndArchiveParms ►►

Put Archive Parameters on Separate Lines

DSNPrefix

Specifies the archive data set name prefix value.

Rules:

- The maximum number of characters for the data set prefix depends on the type of data set. For a GDG data set, the maximum length is 35 characters, and for a sequential data set, the maximum length is 28 characters. This length provides space for the other components of the data set name to be supplied. The maximum length of an MVS data set name is 44 characters.
- The data set prefix must conform to the rules for MVS data set names. The maximum length of any component of the data set name is 8 characters. Each component of the name must be composed of alphanumeric or national characters (\$ # @). See the DD statement information in the [z/OS MVS JCL Reference](#) for more information about data set naming rules.
- The data set prefix can contain system symbolics, for example, &SYSNAME..ARCHIVE. See the coding symbols in JCL in the [z/OS MVS JCL Reference](#) for information about using system symbols.

Unit

Specifies the unit information for the dynamic allocation of the target data set. The format of this parameter should conform to the UNIT parameter on the DD JCL statement. This parameter is optional.

Volume

Specifies the volume information for the dynamic allocation of the target data set. The format of this parameter should conform to the VOLUME parameter on the DD JCL statement. This parameter is optional.

MgmtClas

Specifies the management class information for the dynamic allocation of the target data set. The format of this parameter should conform to the MGMTCLAS parameter on the DD JCL statement. This parameter is optional.

StorClas

Specifies the storage class information for the dynamic allocation of the target data set. The format of this parameter should conform to the STORCLAS parameter on the DD JCL statement. This parameter is optional.

RetPd

Specifies the retention period in days for the dynamic allocation of the target sequential data set. Valid values are in the range 0 - 9 999. This parameter is ignored for GDG data sets. The format of this parameter should conform to the RETPD parameter on the DD JCL statement. This parameter is optional.

Syslogd rule configuration statement

This topic describes the syslogd rule configuration statement and associated information.

Syntax

Each rule statement of the configuration file has the following syntax:

Rule configuration statement

condition (option 1)

condition (option 2)

Parameters

hostspec

- An IPv4 address, for example, 192.168.0.1
- An IPv4 address with a subnet length, for example, 192.168.0.1/24
- An IPv6 address, for example, FEC0::9:42:105:19
- An IPv6 address with a prefix length, for example, FEC0::9:42:105:19/64
- A host name that resolves to an IPv4 or IPv6 address. The host name can be specified with or without the DNS suffix. If specified without the suffix, the suffix is assumed to be one of the suffixes defined to resolver for the host where syslogd is running.

facility

See [“Supported facility names for syslogd” on page 808](#) for details.

priority

See [“Priority codes” on page 810](#) for details.

destination

See [“Supported destinations for syslogd” on page 811](#) for details.

-F

When the destination is a UNIX file, this parameter specifies the access permissions (modes) for the file if the file must be created dynamically. See the description of the /file destination in [“File destinations for syslogd” on page 811](#) for details.

-D

When the destination is a UNIX file, this parameter specifies the access permissions (modes) for the directory part of the file name if the directory (or directories) containing the file must be created dynamically. See the description of the /file destination in [“File destinations for syslogd” on page 811](#) for details.

-N

When the destination is a UNIX file, this parameter specifies a unique qualifier to append to the archive data set prefix specified on the previous instance of the BeginArchiveParms statement. The contents of the existing UNIX file are archived by copying them into the specified archive dataset. The existing UNIX file is re-initialized and ready to receive more messages. See the description of the /file destination in [“File destinations for syslogd” on page 811](#) for details.

Result: The re-initialization of the destination log file causes a new file with the same name to be created as part of the archive process. Ensure that the desired permission bits and file ownership attributes are set as described in [Setting permissions for log files and directories in z/OS Communications Server: IP Configuration Guide](#).

-X

When the destination is a UNIX file, this parameter specifies that the contents of the z/OS UNIX file should be discarded instead of archived when an archive event occurs. The existing UNIX file is re-initialized and ready to receive more messages. The original contents of the file are lost. Even though the -X parameter does not cause the contents of a file to be archived, the file is still governed by archive events. See the description of the /file destination in [“File destinations for syslogd” on page 811](#) for details.

Result: The re-initialization of the destination log file causes a new file with the same name to be created as part of the archive process. Ensure that the desired permission bits and file ownership attributes are set as described in [Setting permissions for log files and directories in z/OS Communications Server: IP Configuration Guide](#).

Restrictions:

- The -F, -D, -N, and -X parameters are only valid when the destination is a z/OS UNIX file system file.
- The -F, -D, -N, and -X parameters are only valid when syslogd is started with the -c option.
- You cannot specify scope information as part of an IP address or a host name.

- You cannot specify the -F or -D parameter with the -N or -X parameter.
- You cannot specify the -N parameter with the -X parameter.

The \t parameter in the syntax diagram is a tab character; the \b parameter is a blank space.

Usage notes for syslogd

- If you run two instances of syslogd, one for local messages and another for network messages, and you also configure the automatic archival function, do not configure the same UNIX file destinations in the two configuration files. The archival function renames, closes, and reopens the UNIX files. If two instances of syslogd are performing the archival function on the same set of files, results of the archival function are unpredictable. The same is true for the configured archive destination data sets. Be sure to configure unique UNIX file destinations and archive data set names for the two syslogd instances.
- When you specify a priority code, all messages with that priority *and higher* are logged at the specified destination. For example, if you specify a priority code of crit, all messages having alert, panic, emerg, and crit priorities are logged. To send all messages with a priority of crit or higher to a user ID of OPER1, you can enter the following rule in the syslogd configuration file.

```
*.crit OPER1
```

- You can combine logging rules and destinations in different ways. For example, to send all messages from the facility name daemon into one file and all messages with a priority of crit or higher into another file, enter the following code:

```
daemon.* /tmp/syslogd/daemon.log
*.crit /tmp/syslogd/crit.log
```

Guideline: If a server sends a message to syslogd with a facility name of daemon and a priority code of crit, the message is logged in both the daemon.log and crit.log files. Likewise, if a server sends a message to syslogd with a facility name of daemon and a priority code of alert, the message is logged in both files.

- Syslogd rules may contain a series of conditions. Each condition is separated from the previous condition by a semicolon. For example, if you want to log all messages from facility name local1 or facility daemon into one file, use the following code:

```
local1.*;daemon.* /tmp/syslogd/local1_daemon.log
```

- A priority code of none tells syslogd not to select any messages for the specified facility. For example, if you want to log all messages from facility name local1 into one file, all messages from the daemon into another file, and all remaining messages into a third file, use the following code:

```
local1.* /tmp/syslogd/local1.log
daemon.* /tmp/syslogd/daemon.log
*.*;local1.none;daemon.none /tmp/syslogd/the_rest.log
```

Conditions with a priority of none are called exclusionary conditions. When using syslogd rules with a series of conditions separated by semicolons, all of the individual conditions are evaluated left-to-right for each message. Each matching condition results in either a TRUE (meaning log the message) or a FALSE (meaning don't log the message). Conditions that don't match are ignored. The final result of evaluating each matching condition left-to-right is the result of the last matching condition. Rules that have no matching conditions for a message result in a FALSE. Matching exclude conditions (those with priority of none) result in a FALSE. As an example, consider the difference between the following two rules for a message with facility of daemon and a priority of emerg.

```
daemon.none;*.emerg /tmp/syslogd/mylogfile
*.emerg;daemon.none /tmp/syslogd/mylogfile
```

The first rule, first condition, results in FALSE. The first rule, second condition, results in TRUE. Therefore, the message will be logged to the destination for this rule. The second rule, first condition, results in TRUE. The second rule, second condition, results in FALSE. The message will not be logged for this rule.

The order of conditions within the filter is significant.

Guideline: If you are logging to a subdirectory in /tmp, you should set up the directory (for example, /tmp/syslog) as a separate z/OS UNIX file system. Unless managed properly, the syslogd daemon can fill up the /tmp hfs, which can impact other applications that might require temporary space in the /tmp directory.

- You can define logging conditions that contain a userid and jobname along with the facility and priority. The user ID value, the job name, or both can be specified as an asterisk (*), which matches any user ID or any job name.

Restrictions:

- Only messages that are issued by a program running under the specified user ID or job name and that also match the facility and priority are logged.
- The user ID and job name filter is used only for messages that originate on the same system where syslogd is running. The filter does not apply for messages received from the IP network.

For example, if you want to log all messages from programs running under userid USER1 (with any jobname, facility or priority) to one file and log all messages from any userid with jobname JOB1 with facility of daemon and any priority to another file, use the following code:

```
user1.*.*.*          /tmp/syslogd/user1.log
*.job1.daemon.*      /tmp/syslogd/job1.daemon.log
```

- You can define logging conditions that contain an IP address or host name along with the facility and priority. If you use a host name, it must be able to be resolved to an IP address.

Restriction: Only messages received over the IP network use a filter containing an IP address or host name.

The IP address or host name filter is not used for local messages received over the syslog AF_UNIX socket. For example, if you want to log all messages from host1.xyz.com to one file and all messages from 192.168.0.1 with facility daemon and priority info or higher to another file, use the following code:

```
(host1.xyz.com).*.*   /tmp/syslogd/host1.log
(192.168.0.1).daemon.info /tmp/syslogd/host2.log
```

- It is possible to create rules that contain an IP address (or host name) in one condition along with *userid.jobname.facility.priority* in another condition.

Rule: Conditions must be separated by semicolons.

- If using IP addresses in conditions, the address can be followed by an optional forward slash and a number representing the number of significant bits of the address. This is called the prefix length. The prefix length provides a means to indicate that a condition applies to all IP addresses that have the bit pattern for the specified number of bits. For example, the following rule matches all messages received from IP addresses 192.168.0.0 - 192.168.0.255 that also have a facility of daemon and a priority of info or higher:

```
(192.168.0.1/24).daemon.info          /tmp/syslogd/host1.log
```

- IPv6 addresses or host names that resolve to IPv6 addresses can be used in the rule conditions or as destinations (if forwarding to another host).

Restriction: Do not use IPv4-mapped IPv6 addresses or IPv6 addresses with the reserved prefix ::/96.

Supported facility names for syslogd

The following facility names are supported and predefined in the syslogd implementation:

user

Message generated by a process (user).

mail

Message generated by mail system.

news

Message generated by news system.

uucp

Message generated by UUCP system.

daemon

This facility name is generally used by server processes. The FTPD server, the RSHD server, the REXECD server, the SNMP agent, and the SNMP subagent use this facility name to log trace messages.

auth/authpriv

Message generated by authorization daemon.

cron

Message generated by the clock daemon.

lpr

Message generated by the (USS lp command) print client.

local0-7

Names for local use. The z/OS UNIX Telnet server uses the local1 facility name for its log messages.

mark

Used for logging MARK messages.

kernel

z/OS does not generate any log messages with the kernel facility, and it does not accept log messages from local applications with the kernel facility. However, syslogd on z/OS is capable of receiving log messages over the network from other syslog daemons using the kernel facility. The kernel facility can be used in rules to direct these log messages to specific destinations.

Facilities used by z/OS Communications Server

Table 53 on page 809 shows the facilities used by z/OS Communications Server.

<i>Table 53. syslogd facilities</i>			
Application	syslogd record identifications	Primary syslog facility	Other syslog facility
Application Transparent Transport Layer Security (AT-TLS)	TTLS	daemon	auth
Automated domain name registration (ADNR)	adnr	daemon	None
Communications Server SMTP (CSSMTP)	CSSMTP	mail	None
Defense Manager daemon (DMD)	DMD	local4	None
FTP server	ftpd, ftps	daemon	None
IKE daemon	IKED	local4	None
Network security services (NSS) server	NSSD	local4	None
Network SLAPM2 subagent	NSLAPM2	daemon	None
OMPROUTE	omproute	user	None
OPORTMAP server	oportmap	daemon	None

Table 53. *syslogd facilities (continued)*

Application	syslogd record identifications	Primary syslog facility	Other syslog facility
OREXECD	rexecd	daemon	auth
ORSHD	rshd	daemon	auth
OTELNETD	telnetd	local1	auth
Policy Agent	Pagent	daemon	None
POPPER	popper	mail	None
PWCHANGE command	pwchange	daemon	None
PWTOKEY command	pwtkey	daemon	None
rpcbind	rpcbind	daemon	None
Simple Network Time Protocol daemon	sntpd	daemon	None
SNMP agent (OSNMPD)	snmpagent	daemon	None
syslogd	syslogd	daemon	None
TCP/IP subagent	M2SubA	daemon	None
TIMED daemon	timed	user	None
TN3270E Telnet subagent	TNSubA	daemon	None
Traffic Regulation Management Daemon (TRMD)	TRMD	daemon (used for IDS logging)	local4 (used for IPSEC logging and defensive filter logging) local5 (used for zERT policy-based enforcement logging)
Trap Forwarder daemon	trapfwd	daemon	None
z/OS Load Balancing Advisor	lbadv	daemon	None
z/OS Load Balancing Agent	lbagent	daemon	None

Priority codes

When you specify a priority code, all messages with that priority and higher are logged at the specified destination. For example, if you specify a priority code of crit, all messages having alert, panic, emerg, and crit priorities are logged.

The following priority codes are supported. They are shown in priority sequence.

emerg/panic

A panic condition was reported to all processes.

alert

A condition that should be corrected immediately.

crit

A critical condition.

err(or)

An error message.

warn(ing)

A warning message.

notice

A condition requiring special handling.

info

A general information message.

debug

A message useful for debugging programs.

none

Do not log any messages for the facility.

Place holder used to represent all priorities.

Supported destinations for syslogd

The following destinations are supported.

File

A specific path (for example, /tmp/syslogd/auth.log). File names are case sensitive. See [“File destinations for syslogd”](#) on page 811.

Remote destination (-A or @host)

A syslog daemon on another host. See [“Remote destinations for syslogd”](#) on page 814.

user1,user2,...

A list of users.

/dev/console

The MVS console.

/dev/operlog

The MVS operlog log stream. See the information about [Planning for system logger applications in z/OS MVS Setting Up a Sysplex](#).

Requirement: The MVS operlog stream must be active for syslogd to be able to write to it.

\$SMF

The log message is stored in SMF record type 109. See the information about [type 109 SMF records in z/OS Communications Server: IP Programmer's Guide and Reference](#) for a description of type 109 SMF records. The maximum SMF message is 4096. If the BPX.SMF facility is defined, then the user ID with which syslogd runs must be permitted to BPX.SMF. See SEZAINST(EZARACF) for more information.

- For example, to send all log messages of severity critical or higher from bpxroot or uswmaint to SMF, use the following statement.

```
bpxroot.*.*.crit;uswmaint.*.*.crit    $SMF
```

File destinations for syslogd

/file

A specific path (for example, /tmp/syslogd/auth.log). All log files used by syslogd must be created in the z/OS UNIX file system before syslogd is started unless the -c start option is specified. If the -c option is specified, the file name can be followed by the -F and -D parameters.

You should use a cron job to signal syslogd at midnight, along with date stamps in the log file directory names, to organize log files by year (%Y), month (%m), and day (%d), only if you do not use the automatic archive function of syslogd. See [Configuring syslogd for automatic archiving in z/OS Communications Server: IP Configuration Guide](#) for more information about automatic archiving.

Because both of these methods rely on creating new log files, results could be unpredictable if you try to use both methods together.

Destination file access parameters

-F

The -F parameter specifies the access permissions (modes) for the file if the file must be created dynamically. This parameter has no effect if the file already exists.

Restriction: You cannot specify the -F parameter with the -N or -X parameter.

-D

The -D parameter specifies the access permissions (modes) for the directory part of the file name if the directory (or directories) containing the file must be created dynamically. This parameter has no effect on a directory that already exists.

Restriction: You cannot specify the -D parameter with the -N or -X parameter.

The value following the -F parameter or the -D parameter uses the same octal values as specified for the start options -F and -D. If the -F and -D options are specified on a rule, these values override, for this rule only, the default values specified by the start options. For example, for syslogd to create the file (and directories if needed) for /tmp/syslogd/auth.log, you could specify a rule like the following example:

```
auth.* /tmp/syslogd/auth.log -F 640 -D 770
```

The permissions in the previous example rule give the owner read/write access to the file and give members of the file's group read-only access. The file's owner ID is set to the process's effective user ID (UID), which for syslogd is always UID 0. By default, the owning group ID (GID) is set to that of the parent directory. However, if the FILE.GROUPOWNER.SETGID profile exists in the UNIXPRIV class, the owning GID is determined by the set-GID bit of the parent directory, as follows:

- If the parent's set-gid bit is on, the owning GID is set to that of the parent directory.
- If the parent's set-gid bit is off, the owning GID is set to the effective GID of the process.

If the /tmp or the /tmp/syslogd directories do not exist, they are created with access permissions of 770.

Destination file archive parameters

The -N and -X parameters are part of the automatic archival function. You should use the -N or -X parameter only if you do not use a cron job to signal syslogd at midnight, along with date stamps in log file directory names, to organize log files by year (%Y), month (%m), and day (%d). See [Configuring syslogd for automatic archiving in z/OS Communications Server: IP Configuration Guide](#) for more information about automatic archiving. Because both of these methods rely on creating new log files, results could be unpredictable if you try to use both methods together.

-N

You can specify the -N parameter following the file name to specify automatic archival options. The -N parameter specifies that the file should be automatically archived when an archive event occurs, and provides a unique qualifier to append to the data set prefix specified on the previous instance of the BeginArchiveParms statement. This prefix forms the base archive data set name. Additional information is appended to the base name to form the complete archive data set name. The format of the additional information depends on the type of data set. You can specify either a GDG or a sequential data set.

Results:

- If you specify the -N parameter multiple times on the same rule, the last instance is used.
- If you have multiple rules that use the same destination file, and you specify a mixture of -N and -X parameters on those rules, the parameter you specify on the first such rule is used.

Restrictions:

- You cannot specify the -N parameter with the -F or -D access parameters.
- The -N parameter is mutually exclusive with the -X archive parameter.
- You cannot archive destination files that are specified on more than 1 rule configuration statement. For example, if you specify the following rule configuration statements:

```
(192.9.200.0/8).local0.info /tmp/syslogd/otherlog -N OTHER.LOG
(127.0.0.0/8).local0.info /tmp/syslogd/otherlog -N OTHER.LOG
```

syslogd will issue the following error message after processing the statements:

```
FSUM1273 SYSLOGD AUTOMATIC ARCHIVE NOT USED FOR RULES WITH SHARED DESTINATION
```

- You cannot use the field descriptors for year, month, or day (e.g, %y, %m, or %d) in the qualifier specified for the -N parameter. For example, the following -N specification is not supported and will result in a syntax error when processed by syslogd:

```
-N D%y%m%d.LOG
```

The syslogd application requires the correct SAF authorization to create the target data sets that are needed for archival purposes.

For a GDG data set, specify (+1) at the end of the qualifier value. For example, -N TRACE(+1). The GDG specifiers (+0) and (-n) are not valid. The complete archive data set name for a GDG data set is:

prefix.qualifier.gdg_suffix

where:

- *prefix* is the value specified on the BeginArchiveParms statement.
- *qualifier* is the value specified on the -N parameter.
- *gdg_suffix* is the value automatically supplied for GDG data sets to make them unique.

If you use GDG data sets as an archive destination, the GDG BASE must already have been created. Also, be aware of the maximum number of generation data sets to be kept for the GDG. It is possible for syslogd to write more than one archive to the GDG per day, because of the multiple triggers used to perform archives. For example, if you keep five generation data sets, and syslogd performs five archives in one day, you are effectively retaining only a single day's worth of data.

See the information about [Configuring syslogd for automatic archiving in z/OS Communications Server: IP Configuration Guide](#) for sample JCL to create a GDG BASE. See [z/OS DFSMS Using Data Sets](#) for more information about GDG data sets.

For a sequential data set do not specify the GDG indicator (+1). The complete archive data set name for a sequential data set is as follows:

prefix.qualifier.date_suffix.time_suffix

where:

- *prefix* is the value specified on the BeginArchiveParms statement.
- *qualifier* is the value specified on the -N parameter.
- *<date_suffix>* is the date value automatically supplied by syslogd for sequential data sets to make them unique. The format of this suffix is: *Dyymmdd*.
- *time_suffix* is the time of day value automatically supplied by syslogd for sequential data sets to make them unique. The format of this suffix is *Thhmmss*.

For example, to make a z/OS UNIX file eligible for automatic archival, you could specify the following rule:

```
auth.* /tmp/syslogd/auth.log -N TRACE
```

-X

You can specify the -X parameter following the file name to indicate that the file should only be re-initialized but not archived when an archive event occurs. The -X parameter is mutually exclusive with the -N parameter.

Restriction: You cannot specify the -X parameter with the -F or -D parameter.

Remote destinations for syslogd

A remote host destination is used to send log data to a syslog daemon on another host. There are 2 options for specifying a remote destination.

1. The forwarding action, -A parameter, allows you to specify the host to which the log data should be sent using either the host name or IP address, the transport protocol (TCP or UDP) and the port. When TCP is used, you can also specify whether the connection should be secured with TLS or not.
2. An older syntax of @host is also supported. However, with this syntax you can only specify the host name or IP address. The UDP transport protocol is always used.

Restrictions:

- You cannot customize the port based on the remote host. The port specified in /etc/services for the syslog udp service (or a default of port 514) is used.
- You cannot use the TCP transport and as a result you cannot use TLS protection.

Syntax for -A

➡ -A(DEST_PARMS) ➡

DEST_PARMS

Parameters

-A

The destination is a syslog daemon on another host.

destination

The host name or IP address of the remote syslog daemon.

This parameter is required. If it is not configured, the rule will be ignored.

protocol

The transport protocol to use for sending to the remote syslog daemon. Possible values are:

- TCP
- UDP

This parameter is required. If it is not configured, the rule will be ignored.

port

The port of the remote syslog daemon. A valid value is in the range 1-65535.

If this parameter is not configured the default value depends on the settings of the protocol and secure parameters.

- If the protocol is UDP, the default is the port configured in /etc/services for the syslog udp service. If the service is not configured in /etc/services, a default of UDP port 514 is used.
- If the protocol is TCP and secure is yes, the default is TCP port 6514.
- If the protocol is TCP and secure is no, the default is TCP port 514.
- If the protocol is TCP and secure is not configured, the default is TCP port 514.

secure

Specifies whether TLS protection is required for the TCP connection used to forward messages. Possible values are yes and no. The default is no.

This parameter is only allowed if the protocol is specified as TCP. If the protocol is UDP and the secure parameter is specified, the rule is ignored.

Rules:

- The parameters can be specified in any order.
- If a parameter is specified more than once and the values are different, the rule is ignored.
- No space is allowed between the -A and the opening parenthesis.
- No spaces are allowed in the specification of a parameter/value.
- One or more spaces are required between parameters.
- If an error is detected in the -A specification, error message FSUM1226 is logged. You can use the -d syslogd start option to get detailed configuration errors. For more information, see [Diagnosing syslogd configuration problems in z/OS Communications Server: IP Configuration Guide](#).

Forwarding action examples:

- The following forwarding action sends messages to the remote syslog daemon at 10.1.2.3 TCP port 6514 and requires TLS protection.

```
-A(destination="10.1.2.3" protocol="TCP" port="6514" secure="yes")
```

- The following forwarding action sends messages to the remote syslog daemon at 10.1.2.3 UDP port 514.

```
-A(destination="10.1.2.3" protocol="UDP" port="514")
```

- The following forwarding action sends messages to the remote syslog daemon at abc.com TCP port 514. TLS protection is not required. The secure parameter defaults to "no".

```
-A(protocol="TCP" port="514" destination="abc.com")
```

Syntax for @host

@host

host is an IP address or host name of a syslog daemon on another host (for example, @host.domain).

Syslogd browser tool

The two steps to enable the syslogd browser ISPF interface are as follows:

1. Provide ISPF library access. You must provide access to the z/OS Communications Server ISPF libraries. You can do this by modifying the TSO logon procedures or by running a CLIST.
2. Add the syslogd browser to the ISPF Primary Option menu or to an ISPF options menu of your choice. To be able to select the syslogd browser interface from your ISPF Primary Option menu, you need to update the menu and processing sections of the ISR@PRIM panel.

Requirement: You must be able to scroll forward and backward in the ISPF interface to access specific information. Be sure that your keyboard has specific keys for Page Up and Page Down or that you have set PF keys for these functions using option 0.3 on the ISPF Primary Option menu. UP or FORWARD works for scrolling forward. DOWN, BACK, or BACKWARD works for scrolling back.

Providing library access

You must provide access to the z/OS Communications Server ISPF libraries. You can do this by performing either of the following actions:

- Adding DD statements to your TSO logon procedure
- Allocating the libraries with a REXX exec

The following ISPF libraries are required for using the syslogd browser ISPF interface:

- *hlq*.SEZAPENU (ISPF panel library; member names all start with EZASY)
- *hlq*.SEZAMENU (ISPF message library; member names all start with EZASY)
- *hlq*.SEZAEXEC (REXX program library)

Using the TSO logon procedure

One method of providing access to the z/OS Communications Server ISPF libraries is to add them to the TSO logon procedure.

Add the following DD statements to your TSO logon procedure, and replace *hlq* with your installation's high level qualifier for z/OS Communications Server libraries:

```
//ISPPLIB DD DSN=hlq.SEZAPENU,DISP=SHR  
//ISPMLIB DD DSN=hlq.SEZAMENU,DISP=SHR
```

and

```
//SYSEXEC DD DSN=hlq.SEZAEXEC,DISP=SHR
```

or

```
//SYSPROC DD DSN=hlq.SEZAEXEC,DISP=SHR
```

Using a CLIST

Another method of providing access to the z/OS Communications Server ISPF libraries is to run a CLIST or a REXX program to allocate the z/OS Communications Server ISPF libraries. Copy *hlq*.SEZAEXEC(EZABROWS) into your system CLIST or REXX library and make changes as indicated in the comments of that member.

Adding the syslogd browser to the ISPF primary option menu

ISR@PRIM is the default ISPF Primary Option menu panel and a member in the ISPPLIB library. If you want all of your users to have access to the syslogd browser from the ISPF primary option menu, you must update the ISR@PRIM member in the following two places:

- In the menu section (Part 1 of ISR@PRIM) to have an option for the syslogd browser appear on the ISPF Primary Option menu. See the example in this topic.
- In the processing section (Part 2 of ISR@PRIM) so that the selection invoke the syslogd browser ISPF interface. You can optionally have the selection execute the initialization CLIST before invoking the syslogd browser. See the examples in [Figure 24 on page 817](#) and [Figure 25 on page 817](#).

After you update ISR@PRIM, the option that you added for the syslogd browser appears on the ISPF Primary Option menu after the next ISPF logon.

[Figure 24 on page 817](#) shows the menu section of the ISPF Primary Option menu for ISR@PRIM.

Chapter 16. Policy Agent and policy applications

For related information about Policy Agent and the policy applications, see the policy based networking information in [z/OS Communications Server: IP Configuration Guide](#).

Also, for more information about policy schema definition files, see [Chapter 18, “Intrusion detection services policy,”](#) on page 1155.

Policy configuration files

This topic contains information about the policy configuration files, including overviews and syntax rules.

Policy Agent configuration files overview

When the Policy Agent is started, the main policy configuration file is used. Use this initial configuration file to point to other policy files that contain specific policies for other corresponding TCP/IP images. Policy files can be stored locally or on a remote system.

There are multiple types of configuration files. The role of the Policy Agent determines which files are used and for what purpose. Policy Agent can act in the role of a policy server, providing centralized policy services for a set of policy clients. It can also act as a policy client, retrieving remote policies from the policy server. The policy client installs these remote policies in the corresponding TCP/IP image. In either case (policy client or policy server), local policies can also be stored in local configuration files. The following configuration files are used on the policy client or policy server to configure operational characteristics or to define local policies:

- Main configuration file (determined using a standard search order); can refer to policy common configuration files
- Common IPsec configuration file (specified on the CommonIpSecConfig statement)
- Common Application Transparent Transport Layer Security (AT-TLS) configuration file (specified on the CommonTTLSConfig statement)
- Common IDS configuration file (specified on the CommonIDSConfig statement)
- Common Routing configuration file (specified on the CommonRoutingConfig statement)
- Image configuration files (specified on the TcpImage or PEPInstance statement); can refer to policy specific image configuration files
- Image IPsec configuration files (specified on the IpSecConfig statement)
- Image AT-TLS configuration files (specified on the TTLSConfig statement)
- Image IDS configuration files (specified on the IDSConfig statement)
- Image QoS configuration files (specified on the QOSConfig statement)
- Image Routing configuration files (specified on the RoutingConfig statement)
- Image zERT policy-based enforcement (ZERT) configuration files (specified on the ZERTConfig statement)

On the policy server, the following configuration files are used to define policies for policy clients:

- Policy client common configuration files (specified on the DynamicConfigPolicyLoad statement)
- Policy client image configuration files (specified on the DynamicConfigPolicyLoad statement)

Tips:

- If the TcpImage or PEPInstance statement does not specify an image configuration file, then the main configuration file is also the image configuration file for that TCP/IP image.

- If the QOSConfig statement is not specified, then QoS policies are defined in the image configuration file, not in a separate image QoS configuration file.

Policy Agent configuration statements overview

The following statements configure basic operational parameters for the Policy Agent, and you can specify them only in the main configuration file:

- AutoMonitorApps
- AutoMonitorParms
- ClientConnection (on the policy server)
- Codepage
- DynamicConfigPolicyLoad (on the policy server)
- LogLevel
- ServerConnection (on the policy client)
- ServicesConnection
- TcpImage or PEPInstance

Use the following statement to configure a policy client to retrieve remote policies from a policy server. Specify this statement in the image configuration file, on a per-stack basis:

- PolicyServer

Use the following statements to configure optional files for some policy types (both common and image-specific files) to obtain local policies:

- CommonIDSConfig
- CommonIPSecConfig
- CommonRoutingConfig
- CommonTTLSSConfig
- IdsConfig
- IPSecConfig
- QOSConfig
- RoutingConfig
- TTLSSConfig
- ZERTConfig

The ReadFromDirectory statement optionally configures the Policy Agent as an LDAP client, and you can specify them in the image configuration files, on a per-stack basis.

The following statements configure functional parameters for the Policy Agent and you can specify them in the image QoS configuration files, on a per-stack basis:

- PolicyPerfMonitorForSDR
- PolicyPerformanceCollection
- SetSubnetPrioTosMask

Table 69 on page 840 shows statements that define policies; you can specify these statements in the image configuration files for each policy type, on a per-stack basis.

General syntax rules for Policy Agent

The following list shows the general configuration rules. Unless otherwise noted, these rules apply to both the configuration file and the Lightweight Directory Access Protocol (LDAP) server:

- Specify Policy Agent configuration files using code page IBM-1047 for EBCDIC, unless the Codepage statement is configured.
- Only one attribute and its values can be specified per line.
- Text beyond the specified attribute and value is ignored.
- Text beginning with the # character is a comment and is ignored, unless documented otherwise.
- Comments beginning with the # character in an LDAP server ldif configuration file might only be recognized as comments at the beginning of the file; therefore do not specify such comments elsewhere in the file, as they are interpreted as part of an attribute or attribute value.
- For most range specifications, the ranges can be delimited by a colon (:), a dash (-), or a blank (), but these delimiters cannot be mixed within a single range specification. IP address ranges cannot use the colon or blank delimiter, unless stated otherwise.
- See [z/OS Communications Server: IPv6 Network and Appl Design Guide](#) for information about types of policies that support IPv6.
- IPv6 policy is installed but is not enforceable in a stack that is not IPv6 enabled.
- IPv4-mapped IPv6 addresses and IPv6 addresses with the reserved prefix ::/96 are valid only for IP filter rules and for the Identity parameter on local and remote security end points.
- The maximum decimal value for numeric values is 4294967295, unless otherwise noted.
- Policy rule and action names are limited to 32 characters. If QoS and IDS LDAP statement names longer than 32 characters are specified, they are silently truncated. All other statements longer than 32 characters cause an error message to be written to the log.
- If a configuration file or LDAP configuration contains duplicate statement or object names, Policy Agent keeps the first or the last statement or object, as follows. The following situations are considered warnings, not errors.
 - For IDS (LDAP) and QoS, Policy Agent keeps the first entry.
 - For IDS (configuration file), IPSec, Routing, AT-TLS and ZERT, Policy Agent keeps the last entry.
- If a QoS or IDS statement or object is defined with the same name in both a configuration file and LDAP, Policy Agent keeps the first such statement or object that it reads. This is typically the statement or object in the configuration file, but as a result of timing constraints, it could also be the statement in LDAP. The last duplicate statement or object is discarded; this is considered an error.
- Specify most attributes for configuration file statements only once per statement (exceptions are noted where appropriate). If you specify multiple attributes, no error or warning messages are written to the log, and the last instance of the attribute is used.
- Attributes for policies defined on an LDAP server can be single- or multi-valued (meaning a single value or multiple values are allowed for that attribute). The Policy Agent detects multiple values for attributes that are defined as single valued, and treats the policy object as in error.
- The policy version is specified by the configuration file statement name, as follows:
 - ServicePolicyRules and ServiceCategories statements specify version 1 policies.
 - PolicyRule and PolicyAction statements specify version 2 policies.

Result: The policy version of LDAP-defined objects is determined by the LDAP_SchemaVersion parameter on the ReadFromDirectory statement.

For more information about policy version definitions, see [z/OS Communications Server: IP Configuration Guide](#). For more information about policy version differences, see [z/OS Communications Server: IP Diagnosis Guide](#).

- Some configuration statements use an inline statement syntax. When a given statement is specified inline within another statement, only the inline statement name is shown in the syntax diagrams. However, the entire statement being inlined must be specified, including its own set of start and end braces ({}) and all parameters.

Tip: The **name** parameter on the statement name might or might not be optional, depending on the specific statement. In the following example, the IpFilterRule statement is included inline within

the `IpFilterGroup` statement. A name is required on the `IpFilterRule` statement, for example, `Rule1All-Permit`, as follows:

```
IpFilterGroup ZoneAll
{
  IpFilterRule Rule1All-Permit
  {
    IpSourceAddr All
    IpDestAddr All
    IpServiceGroupRef Resolver
    IpServiceRef PathMtuDiscovery
    IpServiceGroupRef Ping-Outbound-Only
    IpGenericFilterActionRef permit
  }
}
```

- For named inline statements where the name is optional, a nonpersistent system name is created using the named portion of the statement name with a unique identifier. This prevents reuse of the named inline statement as a reference name.
- Errors detected in a policy rule or action result in that policy object being discarded.
- For IPSec, Routing, AT-TLS or ZERT policies, any errors detected during parsing results in no new policies being installed. For all other policy types, only the policy objects that contain errors are discarded.
- If a rule refers to an action that does not exist (or has been discarded due to an error) then the rule is also discarded.
- If a Routing action refers to a route table that does not exist (or has been discarded as the result of an error), the action is also discarded.
- Some statements, parameters, parameter values, rules, or restrictions apply only to certain release levels. See the [Policy-based networking information in z/OS Communications Server: IP Configuration Guide](#) for more details about mixed release levels when using policy clients with a policy server. The following tables list the definitions that are supported for each release level.

Table 54 on page 822 lists statements, parameters, and parameter values that are no longer supported:

Table 54. Statements, parameters, and parameter values that are no longer supported				
Statement	Parameter	Parameter value	Description/Notes	Last release supported

Policy Agent general configuration file statements

Table 67 on page 837 and Table 68 on page 838 list the Policy Agent general configuration file statements, including the purpose of each statement.

Table 67. Policy Agent main configuration file statements		
Statement	Purpose	See
AutoMonitorApps	Specifies applications to be monitored and automatically started or restarted by Policy Agent.	“AutoMonitorApps statement” on page 845
AutoMonitorParms	Specifies global parameters that control how Policy Agent monitors and starts or restarts applications.	“AutoMonitorParms statement” on page 849
ClientConnection	Configures the Policy Agent as a policy server, listening on the specified port for remote connections.	“ClientConnection statement” on page 850
Codepage	Specifies the EBCDIC code page to be used when reading configuration files and policy definition files.	“Codepage statement” on page 851

<i>Table 67. Policy Agent main configuration file statements (continued)</i>		
Statement	Purpose	See
CommonIDSConfig	Specifies the path of an IDS policy file that contains common IDS policy statements.	“CommonIDSConfig statement” on page 852
CommonIPSecConfig	Specifies the path of an IPSec policy file that contains common IPSec policy statements.	“CommonIPSecConfig statement” on page 853
CommonRoutingConfig	Specifies the path of a Routing policy file that contains common Routing policy statements.	“CommonRoutingConfig statement” on page 853
CommonTTLSConfig	Specifies the path of an AT-TLS policy file that contains common AT-TLS policy statements.	“CommonTTLSConfig statement” on page 854
DynamicConfigPolicyLoad	Specifies the configuration file names to use on the policy server for policy client policies.	“DynamicConfigPolicyLoad statement” on page 855
LogLevel	Specifies level of tracing.	“LogLevel statement” on page 863
ServerConnection	Specifies the connection information used by a policy client to connect to the policy server. This statement includes security information and the location of the policy server.	“ServerConnection statement” on page 880
ServicesConnection	Specifies the listening port, listening TCP/IP image, and security level for connections to this Policy Agent.	“ServicesConnection statement” on page 886
TcpImage and PEPInstance	Defines a TCP/IP image and its associated configurations.	“TcpImage and PEPInstance statement” on page 892

<i>Table 68. Policy Agent image configuration file statements</i>			
Statement	Purpose	File	See
IDSConfig	Specifies the path of an IDS policy file that contains stack-specific IDS policy statements. This statement is required to read an IDS configuration file for a given stack.	Image	“IDSConfig statement” on page 861
IPSecConfig	Specifies the path of an IPSec policy file that contains stack-specific IPSec policy statements. This statement is required to define IPSec policy for a given stack.	Image	“IPSecConfig statement” on page 862

Table 68. Policy Agent image configuration file statements (continued)

Statement	Purpose	File	See

ZERTSSHProtocol	Defines SSH protocol version	ZERT	“ZERTSSHProtocol statement” on page 1118

Table 69. Policy Agent configuration file policy statements (continued)

Statement	Purpose	Type	See
ZERTSymmetricEncryption	Defines symmetric encryption algorithm	ZERT	“ZERTSymmetricEncryption statement” on page 1119
ZERTTLSProtocol	Defines TLS protocol version	ZERT	“ZERTTLSProtocol statement” on page 1121

Rules:

- For statements of type QoS, policies are configured in the image or QoS image configuration file.
- For statements of type IDS, policies are configured in the common or image IDS configuration files.
- For statements of type IPSec, policies are configured in the common or image IPSec configuration files.
- For statements of type Routing, policies are configured in the common or image Routing configuration file.
- For statements of type AT-TLS, policies are configured in the common or image AT-TLS configuration files.
- For statements of type ZERT, policies are configured in the image ZERT configuration file.
- For statements of type Reusable, policies are configured in the common or image IDS, IPSec, AT-TLS, Routing configuration files, or ZERT image configuration files.

AutoMonitorApps statement

You can configure the Policy Agent to monitor and automatically start or restart a set of related applications. The following set of applications can be monitored:

- Defense Manager daemon (DMD)
- IKE daemon (IKED)
- Network Security Server daemon (NSSD)
- Syslog daemon (SYSLOGD)
- Traffic Regulation Manager daemon (TRMD)

Use the AutoMonitorParms statement to configure global parameters that control how the Policy Agent monitors and starts or restarts these applications.

Use the AutoMonitorApps statement to configure which applications should be monitored and to specify application-specific parameters.

Restriction: To automatically monitor applications, Policy Agent must be started with a user ID that has superuser authority UID(0). For sample RACF commands, see the EZARACF member of SEZAINST.

Results:

- If you configure applications to be automatically started and restarted, be aware of the following results:
 - If you start the Policy Agent after you have already started an application to be monitored, Policy Agent starts monitoring the application (if it was originally started with the same job name that is configured to the Policy Agent). If the application needs to be restarted later, it is restarted using the cataloged procedure configured to the Policy Agent. This might not be the same procedure that was originally used to start the application.
 - If you start the Policy Agent after you have already started an application to be monitored, but the application does not use the same job name that is configured to the Policy Agent, the Policy

Agent cannot detect that the application is active. Policy Agent tries to start another instance of the application, and this start is likely to fail.

Tip: If you configure applications to be monitored by the Policy Agent, ensure that those applications are not running before you start the Policy Agent. Sometimes you might need to start syslogd before starting the Policy Agent. If you start syslogd before starting the Policy Agent, ensure that Policy Agent is configured with the correct syslogd job name.

- If this statement is removed, or one or more AppName parameters or instances of the TcpImageName parameter are removed, Policy Agent stops monitoring the affected applications. You must stop or restart the applications if needed.
- If one or more AppName parameters, or instances of the TcpImageName parameter are added, Policy Agent starts the affected applications and begins monitoring them.
- If any of the parameters other than AppName or TcpImageName are added, removed, or changed, Policy Agent stops and restarts the affected applications.

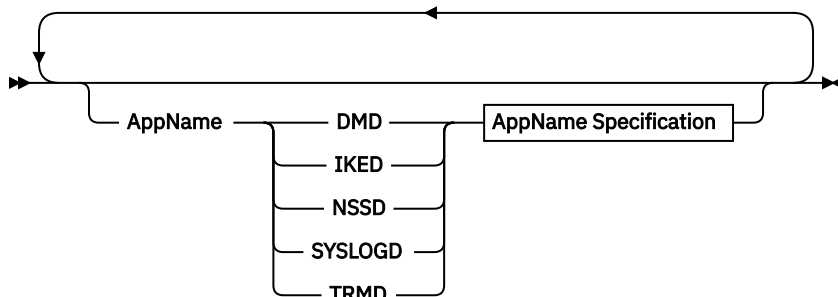

Syntax

➤➤ AutoMonitorApps — Put Braces and Parameters on Separate Lines ➤➤

Put Braces and Parameters on Separate Lines

AutoMonitorApps Parameters

AppName Specification

MultiImage Specification

TcpImageName Specification

AppName Specification Parameters

Parameters

AppName

Specifies which applications you need to monitor and automatically start and restart. Repeat this parameter for each application.

TcpImageName

A string 1 - 8 characters in length that specifies the TCP/IP images on which the application runs. Repeat this parameter for each image.

Rules:

- This parameter is required and valid only for applications that run a separate instance for each TCP/IP image. Currently, the only application that does this is TRMD.
- You can specify a maximum of eight unique TcpImageName parameters for a given AppName parameter.
- You must configure the specified TCP/IP image on a TcpImage statement.

Results:

- In a single stack (INET) environment, the application runs on the active TCP/IP image.
- In a common INET (CINET) environment, if you do not specify the TCP/IP image name, the application runs on the default TCP/IP image (resolver supplied TCPIPuserid statement or TCPIPjobname statement). If the default TCP/IP image cannot be determined, the Policy Agent uses the name INET and the Policy agent creates an internal TcpImage statement with default values to represent the specified TCP/IP image.
- If the TcpImage statement for the specified TcpImageName is removed, Policy Agent stops monitoring the application for that TCP/IP image.

ProcName

A string 1 - 8 characters in length that specifies the name of a cataloged procedure that is used to start the application. A sample procedure is included in SEZAINST(EZAPOLPR).

Tip: You can use a single generic cataloged procedure for all configured applications. Parameters are passed to the start procedure to identify the application name and application-specific parameters. If you use a single procedure, then all started applications run under the same user ID. If you want to use different user IDs for each application, specify different procedure names for the applications using this parameter.

Rule: The specified procedure must contain the JCL parameters listed in [Table 70 on page 848](#).

Table 70. JCL parameters		
Procedure variable	Description	Value passed by the Policy Agent
PROG	Specifies the name of the application program executable.	One of the following supported application names: <ul style="list-style-type: none"> • DMD • IKED • NSSD • SYSLOGD • TRMD
VARS	Specifies the name of a temporary file containing environment variables for the application.	Temporary file name generated by the Policy Agent.
PARMS	Specifies start parameters for the application.	The string specified on the StartParms parameter on the AutoMonitorApps statement, or a null string.

Jobname

A string 1 - 8 characters in length that specifies the runtime job name for the application.

Rules:

- For applications that do not use the TcpImageName parameter, this parameter is optional. The default is the value specified with the AppName parameter.
- For applications that use the TcpImageName parameter, this parameter is required so that the job name for each instance is unique.

StartParms

A string 1 - 45 characters in length that specifies the start parameters for the application. Specify the parameters in the same way that you would specify them on the PARM parameter on the EXEC JCL statement, but do not include single quotation marks. For example:

```
StartParms -d 1
```

EnvVar

A string 1 - 1 024 characters in length that specifies environment variables for the application. Repeat this parameter for each environment variable. Specify the environment variable name and the value, separated by an equal sign. The following examples show how this parameter can be used:

- To specify the configuration file for the IKED, use the following code:

```
EnvVar IKED_FILE=/etc/iked.conf
```

- To specify the resolver configuration file for the TRMD, use the following code:

```
EnvVar RESOLVER_CONFIG=// 'SYS1.TCPPARMS(TCPDATA2) '
```

- To specify the time zone for the NSSD, use the following code:

```
EnvVar TZ=EST5EDT
```

Examples

This example shows how to specify parameters for the following types of applications:

- An application without stack affinity, which means that a single copy of the application runs regardless of how many TCP/IP stacks are running. This example uses the IKED as such an application.
- An application with stack affinity, which means that one instance of the application runs on each TCP/IP stack. This example uses TRMD as such an application.

```
AutoMonitorApps
{
  AppName      IKED
  {
    Procname    POLPROC
  }
  AppName      TRMD
  {
    TcpImageName TCPIP1
    {
      Procname    POLPROC
      Jobname      TRMD1
    }
    TcpImageName TCPIP3
    {
      Procname    POLPROC
      Jobname      TRMD3
    }
  }
}
```

AutoMonitorParms statement

Use the AutoMonitorParms statement to configure the Policy Agent to monitor and automatically start or restart a set of related applications. The following set of applications can be monitored:

- Defense Manager daemon (DMD)
- IKE daemon (IKED)
- Network Security Server daemon (NSSD)
- Syslog daemon (SYSLOGD)
- Traffic Regulation Manager daemon (TRMD)

Use the AutoMonitorApps statement to configure what applications should be monitored and to specify application-specific parameters.

Use this statement to configure global parameters that control how the Policy Agent monitors and starts or restarts the configured applications. If the default values for all parameters are acceptable, you do not need to use this statement.

Results:

- If this statement is removed, the default values are applied when the previously specified MonitorInterval value expires.
- If this statement is added, the new values are applied when the previous default MonitorInterval value expires.
- If any changes are made to this statement, the new values are applied when the previously specified MonitorInterval value expires.

Syntax

►► AutoMonitorParms — Put Braces and Parameters on Separate Lines ◄◄

Put Braces and Parameters on Separate Lines

AutoMonitorParms Parameters

Parameters

MonitorInterval

Specifies the interval, in seconds, at which an application should be monitored to determine if that application is still running. Valid values are in the range 1 - 86400. The default value is 10 seconds.

RetryLimitCount

Specifies the number of times that Policy Agent should start or restart an application within the time period specified by the RetryLimitPeriod parameter. Valid values are in the range 1 - 99. The default value is 5.

Each time an application is started, Policy Agent waits 1 minute for the application to start. If it does not start, Policy Agent tries to start it again until the limit specified by this parameter is reached. If the application still has not started, Policy Agent stops monitoring the application until a MODIFY MON,START command is issued for the application. For example, if the application is the IKED, the MODIFY *procname*,MON,START,IKED command causes Policy Agent to resume trying to start the application. See [MODIFY command in z/OS Communications Server: IP System Administrator's Commands](#) for information about using MODIFY commands to manage the monitored applications.

RetryLimitPeriod

Specifies the time interval, in seconds, at which Policy Agent should try to start or restart an application. See the RetryLimitCount parameter in this topic for more details. Valid values are in the range 1 - 86400. The default value is 600 (10 minutes).

ClientConnection statement

The Policy Agent acting as a policy server uses the ClientConnection statement to specify the listening port. The Policy Agent acting as a policy client uses this connection to retrieve remote policies.

Results:

- An error is flagged if both the ClientConnection and ServerConnection statements are configured on the same Policy Agent. The result is that there is no connection between the policy server and policy client.
- If the ClientConnection statement is removed, all connections to policy clients are disconnected.
- Updates to the ClientConnection statement are used only for new client connections to the policy server.

Syntax

Parameters

port

Specifies the port that the policy server listens on for TCP connections from policy clients. This port must be the same as the ServerPort value specified on the ServerConnection statement for any policy clients that connect to this policy server.

The valid port values are in the range 1 - 65 535. The default port value is 16 310.

This statement is optional. If a ClientConnection statement is not configured, then the Policy Agent does not act as a policy server, and only listens for local connections using AF_UNIX sockets.

Result: If the port value is updated, then the policy server listens for TCP connections using the updated value.

Restriction: The port value cannot match the port value configured on the ServicesConnection statement.

Codepage statement

Use the Codepage statement to specify the EBCDIC code page to be used for reading all configuration files and policy definition files. The default is IBM-1047. All statements read from the files are converted to the IBM-1047 code page from the specified code page.

Result: If you specify a code page that is not one of the supported values, then Policy Agent issues a warning message to the log file and tries to read the configuration files using the IBM-1047 code page. It is possible that configuration errors might be detected in this case.

Syntax

►► Codepage — *codepage* ◄◄

Parameters

codepage

Specifies the EBCDIC code page to be used. The default code page is IBM-1047 if this statement is not specified. The following code pages are supported:

- IBM-037
- IBM-273
- IBM-274
- IBM-275
- IBM-277
- IBM-278
- IBM-280
- IBM-281
- IBM-282
- IBM-284
- IBM-285
- IBM-297
- IBM-500
- IBM-871
- IBM-1047
- IBM-1140

- IBM-1141
- IBM-1142
- IBM-1143
- IBM-1144
- IBM-1145
- IBM-1146
- IBM-1147
- IBM-1148
- IBM-1149

CommonIDSConfig statement

Use the CommonIDSConfig statement to specify the path of a local IDS policy file that contains common IDS policy statements. These common statements can be referenced from a stack-specific IDS policy file. To define a common set of policies for multiple stacks, use the IDSConfig statement to specify the same file as the CommonIDSConfig statement.

Stack-specific IDS policies are defined in a stack-specific IDS policy file. A stack-specific IDS policy file is identified by an IDSConfig statement.

The refresh interval for the CommonIDSConfig file is inherited from the main configuration file.

Specify the IDSConfig statement without a path name in each image configuration file to define a common set of policies for multiple stacks.

Restriction: The CommonIDSConfig statement can appear only in the main configuration file.

If a CommonIDSConfig statement appears multiple times in the main configuration file, the last occurrence of the statement is used. If the CommonIDSConfig statement appears in an image configuration file, it is ignored.

The configuration information defined in the file identified with the CommonIDSConfig statement is prepended to the configuration information defined in files identified with the IDSConfig statement. This action has the following consequences:

- If no IDSConfig statements are specified, then the CommonIDSConfig file is not parsed by Policy Agent.

Requirement: The IDSConfig statement is required if IDS configuration files exist for a given stack.

- If multiple stacks are defined, the CommonIDSConfig file is parsed for each stack; thus, any errors contained in the file are reported multiple times.

Syntax

➡ CommonIDSConfig — *path* ➡

Parameters

path

The path of the common IDS policy file to be installed.

You can specify an MVS data set name or a z/OS UNIX file name. MVS data set names must be enclosed in single quotation marks (") and must be preceded by a double slash (for example, //). The following examples show both types of names:

```
CommonIDSConfig // 'USER1.PAGENT.CONF(COMIDS) '
CommonIDSConfig /u/user1/pagent.common.ids
```

Restriction: Dynamic monitoring for file updates using the -i startup option is supported only for file-system files; MVS data sets are not monitored for changes.

CommonIPSecConfig statement

Use the CommonIPSecConfig statement to specify the path of a local IPSec policy file that contains common IPSec policy statements. These common statements can be referenced from a stack-specific IPSec policy file. To define a common set of policies for multiple stacks, the IpSecConfig statement can specify the same file as the CommonIPSecConfig statement.

Stack-specific IPSec policies are defined in an IPSec stack-specific policy file. A stack-specific IPSec policy file is identified by an IpSecConfig statement. The refresh interval for the CommonIPSecConfig file is inherited from the main configuration file.

Specify the IPsecConfig statement without a path name in each image configuration file to define a common set of policies for multiple stacks.

Restriction: The CommonIPSecConfig statement can appear only in the main configuration file.

If a CommonIPSecConfig statement appears multiple times in the main configuration file, the last occurrence of the statement is used. If the CommonIPSecConfig statement appears in the image configuration file, it is ignored (unless the main and image configuration files are the same file).

The configuration information defined in the file identified with the CommonIPSecConfig statement is prepended to the configuration information defined in files identified with the IPsecConfig statement. This action has the following consequences:

- If no IPsecConfig statements are specified, then the CommonIPSecConfig file is not parsed by Policy Agent.

Requirement: The IPsecConfig statement is required to define IPSec policy for a given stack.

- If multiple stacks are defined, the CommonIPSecConfig file is parsed for each stack; any errors contained in the file are reported multiple times.

Syntax

➤ CommonIPSecConfig — *path* ➤

Parameters

path

The path of the common IPSec policy file to be installed.

You can specify an MVS data set name or a UNIX file name. MVS data set names must be enclosed in single quotation marks (' ') and preceded by a double slash (/). The following examples show both types of names:

```
CommonIPSecConfig  //'USER1.PAGENT.CONF(COMIPSEC)'  
CommonIPSecConfig  /u/user1/pagent.common.ipsec
```

Restriction: Dynamic monitoring for file updates using the -i startup option is supported only for z/OS UNIX files; MVS data sets are not monitored for changes.

CommonRoutingConfig statement

Use the CommonRoutingConfig statement to specify the path of a local Routing policy file that contains common Routing policy statements. These common statements can be referenced from a stack-specific Routing policy file. To define a common set of policies for multiple stacks, use the RoutingConfig statement to specify the same file as the CommonRoutingConfig statement.

Stack-specific Routing policies are defined in a stack-specific Routing policy file. A stack-specific Routing policy file is identified by a RoutingConfig statement.

The refresh interval for the CommonRoutingConfig file is inherited from the main configuration file.

Specify the RoutingConfig statement without a path name in each image configuration file to define a common set of policies for multiple stacks.

Restriction: The CommonRoutingConfig statement can appear only in the main configuration file.

If a CommonRoutingConfig statement appears multiple times in the main configuration file, the last occurrence of the statement is used. If the CommonRoutingConfig statement appears in an image configuration file, it is ignored.

The configuration information defined in the file identified with the CommonRoutingConfig statement is prepended to the configuration information defined in files identified with the RoutingConfig statement. This action has the following consequences:

- If no RoutingConfig statements are specified, then the CommonRoutingConfig file is not parsed by Policy Agent.

Requirement: The RoutingConfig statement is required if Routing configuration files exist for a given stack.

- If multiple stacks are defined, the CommonRoutingConfig file is parsed for each stack; thus, any errors contained in the file are reported multiple times.

Syntax

►► CommonRoutingConfig — *path* ►►

Parameters

path

The path of the common Routing policy file to be installed.

You can specify an MVS data set name or a UNIX file name. MVS data set names must be enclosed in single quotation marks (' ') and preceded by a double slash (/). Following are examples of both types of names:

```
CommonRoutingConfig  //'USER1.PAGENT.CONF(COMROUT) '  
CommonRoutingConfig  /u/user1/pagent.common.routing
```

Restriction: Dynamic monitoring for file updates using the -i startup option is supported for z/OS UNIX files only; MVS data sets are not monitored for changes.

CommonTTLSTLSConfig statement

Use the CommonTTLSTLSConfig statement to specify the path of a local AT-TLS policy file that contains common AT-TLS policy statements. These common statements can be referenced from a stack-specific AT-TLS policy file. To define a common set of policies for multiple stacks, the TTLSTLSConfig statement can specify the same file as the CommonTTLSTLSConfig statement.

Stack-specific AT-TLS policies are defined in a stack-specific AT-TLS policy file. A stack-specific AT-TLS policy file is identified by a TTLSTLSConfig statement.

The refresh interval for the CommonTTLSTLSConfig file is inherited from the main configuration file.

Specify the TTLSTLSConfig statement without a path name in each image configuration file to define a common set of policies for multiple stacks.

Restriction: The CommonTTLSTLSConfig statement can appear only in the main configuration file.

If a CommonTTLSSConfig statement appears multiple times in the main configuration file, the last occurrence of the statement is used. If the CommonTTLSSConfig statement appears in an image configuration file, it is ignored (unless the main and image configuration files are the same file).

The configuration information defined in the file identified with the CommonTTLSSConfig statement is prepended to the configuration information defined in files identified with the TTLSSConfig statement. This action has the following consequences:

- If no TTLSSConfig statements are specified, then the CommonTTLSSConfig file is not parsed by Policy Agent.

Requirement: The TTLSSConfig statement is required to define AT-TLS policy for a given stack.

- If multiple stacks are defined, the CommonTTLSSConfig file is parsed for each stack, so any errors contained in the file are reported multiple times.

Syntax

►► CommonTTLSSConfig — *path* ►►

Parameters

path

The path of the common AT-TLS policy file to be installed.

You can specify an MVS data set name or a UNIX file name. MVS data set names must be enclosed in single quotation marks (' ') and preceded by a double slash (/). Following are examples of both types of names:

```
CommonTTLSSConfig  //'USER1.PAGENT.CONF(COMTTLS) '  
CommonTTLSSConfig  /u/user1/pagent.common.ttls
```

Restriction: Dynamic monitoring for file updates using the -i startup option is supported for z/OS UNIX files only; MVS data sets are not monitored for changes.

DynamicConfigPolicyLoad statement

The Policy Agent acting as a policy server uses the DynamicConfigPolicyLoad statement to obtain the file names of the configuration files to be retrieved by policy clients.

The DynamicConfigPolicyLoad statement can appear only in the main configuration file.

For each policy type the policy client files are read only after the policy client connects to the policy server. A DynamicConfigPolicyLoad statement (or default values) is bound to a policy client for the life of that client, until one of the following occurs:

- The policy client disconnects from the policy server.
- The connection between the policy server and policy client ends.
- The associated DynamicConfigPolicyLoad statement is removed.

Result: When a DynamicConfigPolicyLoad statement is removed, the policy clients that were using that statement change to use another statement, or default values.

The policy client policies are removed from the policy server in the following cases:

- The policy client disconnects from the policy server.
- The connection between the policy server and the policy client ends.
- The policy client requests that remote policies for a specific policy type be unloaded from the policy server.
- The associated DynamicConfigPolicyLoad statement is removed.

To retrieve remote policies with the policy client, you must define security product authority in the SERVAUTH class for the policy client's user ID; the user ID is defined on the Userid parameter on the PolicyServer statement. The ClientName parameter on the PolicyServer statement is used as the image name. For more information, see the [general policy agent configuration information in z/OS Communications Server: IP Configuration Guide](#). Wildcard values are allowed in profile names. The following example shows the structure of the security product profile:

```
EZB.PAGENT.sysname.image.ptype
```

Multiple DynamicConfigPolicyLoad statements can appear in the main configuration file. The policy server maintains a list of these DynamicConfigPolicyLoad statements. When a policy client connects to the policy server, then the policy client name configured on the PolicyServer statement is matched to the *clientname* parameter. The names are case sensitive with regard to matching. This *clientname* parameter can be a regular expression. The policy server matches these names in the following order:

1. A *clientname* parameter that has an exact match to the policy client name. The policy client name must not contain any regular expression characters.
2. A regular expression *clientname* parameter that matches the policy client name. The longest matching regular expression is chosen. If multiple statements match with the same length *clientname* parameter, the statement chosen is based on alphabetical order.
3. If there is no matching *clientname* parameter or a matching *clientname* value does not have a corresponding PolicyType parameter for this policy type, then the following default remote files are used:
 - Stack-specific remote files used for each policy type:
 - IDS - /etc/pagent_remote.ids
 - IPsec - /etc/pagent_remote.ipsec
 - QoS - /etc/pagent_remote.qos
 - Routing - /etc/pagent_remote.routing
 - AT-TLS - /etc/pagent_remote.ttls
 - ZERT - /etc/pagent_remote.zert
 - For any default stack-specific remote file used, there is no corresponding common configuration file.
 - If no matching *clientname* parameter is found, then the refresh interval is set to 30 minutes.

Result: The PolicyLoad and CommonPolicyLoad parameters are optional; however, if neither the PolicyLoad parameter or the CommonPolicyLoad parameters are configured, this DynamicConfigPolicyLoad statement results in an error and the statement is discarded.

Syntax

➤ DynamicConfigPolicyLoad — *clientname* — Put Braces and Parameters on Separate Lines ➤

Put Braces and Parameters on Separate Lines

DynamicConfigPolicyLoad Parameters

PolicyTypeSpecification

PolicyTypeSpecification Parameters

Parameters

clientname

A string 1 - 24 characters in length specifying the client name to be matched to the policy client name.

Requirement: If this is a regular expression, the string must consist of 1 - 511 characters. Otherwise, it must consist of 1-24 characters.

This *clientname* parameter is used to match the policy client name when it connects to Policy Agent to derive its policy files.

The *clientname* parameter can also consist of a regular expression. The simplest form of regular expression is a string of characters without a special meaning. Such a string matches only itself. [Table 71 on page 857](#) shows the characters with special meaning:

Table 71. Characters with special meaning	
Symbol	Description
.	The period symbol matches any one character except the terminal newline character.
[character–character]	The hyphen symbol (-), within square brackets, means through. It fills in the intervening characters according to the current collating sequence. For example, [a–z] can be equivalent to [abc...xyz] or, with a different collating sequence, it can be equivalent to [aAbBcC...xXyYzZ].

Table 71. Characters with special meaning (continued)	
Symbol	Description
[string]	A string within square brackets specifies any of the characters in the string. Thus [abc], if compared to other strings, matches any that contain a, b, or c.
[m] [m,] [m,u]	Integer values enclosed within square brackets indicate the number of times to apply the preceding regular expression. The m value is the minimum number, and the u value is the maximum number. The u value must be less than 256. If you specify only the m value, it indicates the exact number of times to apply the regular expression. [m,] is equivalent to [m,u]. They both match m or more occurrences of the expression. The plus (+) and asterisk (*) operations are equivalent to [1,] and [0,], respectively.
*	The asterisk (*) indicates 0 or more of any characters. For example, [a*e] matches any of the following: 99ae9, aaaaae, or a999e99.
^	The caret symbol matches the beginning of the string.
\$	The dollar symbol matches the end of the string. (Use \n to match a newline character.)
+	The plus symbol specifies one or more occurrences of a character. Thus, smith+ern is equivalent to smithhhern.
[^string]	The caret symbol inside square brackets, negates the characters within the square brackets. Thus [^abc] matches any characters except a, b, or c.
(expression)	Groups a sub-expression allowing an operator, such as * or +, to work on the sub-expression enclosed in parentheses. For example, (a*(cb+)*).

Rules:

- Do not use multibyte characters.
- You can use the right square bracket (]) alone within a pair of square brackets, but only if it immediately follows either the opening left square bracket or if it immediately follows [^ . For example, []-] matches the] and – characters.
- All the preceding symbols are special. Precede them with a slash (\) to use the symbol itself. For example, a \. e is equivalent to a.e.
- You can use the hyphen (-) by itself, but only if it is the first or last character in the expression. For example, the expression []--0] matches either the] or else the characters – through 0. Otherwise, use \- .
- If duplicate DynamicConfigPolicyLoad statements with the same *clientname* parameter are specified, Policy Agent keeps the last entry.

- If a matching DynamicConfigPolicyLoad statement cannot be found, then the default stack-specific remote policy file is used.
- You cannot specify duplicate symbolic values in a single file name. For example, you cannot specify /etc/\$1.\$2_\$1.
- You cannot use both wildcard and symbolic values in the same file name. For example, you cannot use /etc/\$1.*.

PolicyType

Indicates additional policy configuration information for a specific policy type.

Rule: If duplicate PolicyType parameters for the same policy type are configured, then the policy server keeps the last entry for that policy type.

RefreshInterval

Specifies the time interval (in seconds) that lapses between checks for changes to the creation or modification time of the common and stack-specific remote policy files. This attribute applies to all configured policy types. In the following cases, the update interval is changed:

- If a value is not specified, the default is 1 800 seconds (30 minutes).
- If a value of 0 is specified, the default value of 1 800 seconds (30 minutes) is used.
- Any value from 1 to 299 is rounded up to 300 seconds (5 minutes).

For example, if the refresh interval is set to 300, the corresponding policy file is checked for changes every five minutes. If the policy file changed within the last 5 minutes, it is read again. Any new, changed, or deleted policies are either added to or removed from the policy client configuration.

Result: If the RefreshInterval parameter is updated, this new refresh interval takes effect the next time these policies are refreshed.

Restriction: Dynamic monitoring for file updates using the -i startup option is not supported for files configured on the DynamicConfigPolicyLoad statement.

CommonPolicyLoad

The path of the common remote policy file to be used for the defined policy type.

You can specify an MVS data set name or a z/OS UNIX file name. MVS data set names must be enclosed in single quotation marks (') and preceded by a double slash (/). Following are examples of both types of names:

```
DynamicConfigPolicyLoad (.*)(.*)
{
  PolicyType IDS
  {
    CommonPolicyLoad //'USER1.PAGENT.REMCONF(COMIDS)'
    PolicyLoad       //'USER1.PAGENT.REMCONF(IDS)'
  }
  PolicyType TTLS
  {
    CommonPolicyLoad /u/user1/pagent.remote.common.ttls
    PolicyLoad       /u/user1/pagent.remote.ttls
  }
}
```

The common remote policy file statements can be referenced from the stack-specific remote policy file of the associated policy configuration. Stack-specific remote policies are defined in the stack-specific remote policy file within the same policy configuration. A stack-specific remote policy file is identified by the PolicyLoad parameter.

The configuration information defined in the file identified with the CommonPolicyLoad parameter is prepended to the configuration information defined in the file identified with the PolicyLoad parameter.

Rule: If the DynamicConfigPolicyLoad statement matches multiple policy clients, then the CommonPolicyLoad file is parsed for each policy client. Any errors contained in the file are reported multiple times.

Restrictions:

- Dynamic monitoring for file updates using the -istartup option is not supported for the common remote policy file.
- The CommonPolicyLoad parameter is not supported for PolicyType QoS or ZERT.

Results:

- When the common remote policy file is an MVS data set, it is reread at each refresh interval, regardless of whether it has actually been changed or not. The policy server also rereads all the associated stack-specific remote policy files when the common remote policy file is reread.
- If the CommonPolicyLoad parameter file name is updated, this new common file is read when policies are refreshed.

PolicyLoad

The path of the stack-specific remote policy file to be used for the defined policy type.

You can specify an MVS data set name or a z/OS UNIX file name. MVS data set names must be enclosed in single quotation marks (' ') and preceded by a double slash (/). Following are examples of both types of names:

```
DynamicConfigPolicyLoad (.*)(.*)
{
  PolicyType IDS
  {
    CommonPolicyLoad //'USER1.PAGENT.REMCONF(COMIDS)'
    PolicyLoad      //'USER1.PAGENT.REMCONF(IDS)'
  }
  PolicyType TTLS
  {
    CommonPolicyLoad /u/user1/pagent.remote.common.ttls
    PolicyLoad      /u/user1/pagent.remote.ttls
  }
}
```

Rules:

- If the PolicyLoad parameter is not specified, then the associated common remote policy file specified on the CommonPolicyLoad parameter is used.
- The client names and DynamicConfigPolicyLoad statement names are case sensitive, but MVS data set names are not. Therefore, use caution when defining MVS data set configuration files that include a wildcard to be substituted with the client name. For example, the client names client42 and Client42, if used as a substitution variable in an MVS data set name, would result in the same configuration file being used for both clients.

Results:

- The path name can contain a single wildcard character (*). The policy client name replaces the wildcard position to obtain the stack-specific remote policy file.

The following examples use a wildcard path for an IPSec file:

```
PolicyLoad      //'ETC.REMOTE.CONF(*)'
policy client name = Remote1
Stack-specific remote IPSec policy file is:
//'ETC.REMOTE.CONF(REMOTE1)'
```

```
PolicyLoad      /etc/*.remote
policy client name = REMOTE1
Stack-specific remote IPSec policy file is:
/etc/REMOTE1.remote
```

- The path name can contain symbolic replacement values \$0 through \$9. \$0 represents the entire portion of the client name that matched, while \$1 through \$9 represent portions of the client name that match corresponding parenthesized sub-expressions in the regular expression.

Example of using symbolic replacement values for an IDS file:

```
Regular expression = ^([A-Z].+[a-z]+)\.([A-Z].+[a-z]+)$
```

```
PolicyLoad    //'ETC.$1($2)'  
  
policy client name = SYSa.IDSClient  
Stack-specific remote IDS policy file will be: //'ETC.SYSA(IDSCLIENT)
```

Result: If more symbolic replacement values are specified in a file name than there are parenthesized sub-expressions in the regular expression, the extra symbolic replacement values are not replaced and exist as literal values in the file name.

Restriction: Dynamic monitoring for file updates using the `-istartup` option is not supported for the stack-specific remote policy file.

Results:

- When the stack-specific remote policy file is an MVS data set, it is reread at each refresh interval, regardless of whether it has actually been changed or not.
- If the PolicyLoad parameter file name is updated, the new stack-specific file is read when policies are refreshed.

IDSConfig statement

Use the IDSConfig statement to specify the path of a local IDS policy file that contains stack-specific IDS policy statements.

Requirement: The IDSConfig statement is required to define IDS configuration file policy for a given stack.

Specify the IDSConfig statement without a path name in each image configuration file to define a common set of policies for multiple stacks.

Results: For the associated TCP/IP image on the policy client, if the PolicyServer statement specifies remote IDS policies, then the following occurs:

- If no local IDS policies are installed, then the IDSConfig statement is ignored.
- If local IDS policies are already installed, the result is the same as if the IDSConfig statement had been deleted.

Use the FLUSH/NOFLUSH and PURGE/NOPURGE parameters to specify whether or not IDS policies are deleted at startup (and when a MODIFY PAGENT,REFRESH command is issued) and shutdown, respectively.

The refresh interval for the IDSConfig file is inherited from the image configuration file containing the corresponding IDSConfig statement.

Restriction: The IDSConfig statement can appear only in an image configuration file.

If an IDSConfig statement appears multiple times in an image configuration file, the last occurrence of the statement is used. If the IDSConfig statement appears in the main configuration file, it is ignored (unless the main and image configuration files are the same file).

Syntax

Parameters

path

Specifies the path of the stack-specific IDS policy file to be installed. If no path name is specified, the common IDS policy file specified on the CommonIDSConfig statement is used.

You can specify an MVS data set name or a x/OS UNIX file name. MVS data set names must be enclosed in single quotation marks (' ') and preceded by a double slash (/). Following are examples of both types of names:

```
IDSConfig // 'USER1.PAGENT.CONF(IDS) '  
IDSConfig /u/user1/pagent.ids
```

Restriction: Dynamic monitoring for file updates using the `-i` startup option is supported only for file-system files; MVS data sets are not monitored for changes.

FLUSH

Specifies that all policies installed in the Policy Agent and the TCP/IP stack are deleted. Policies are flushed when the following occurs:

- A new TcpImage statement is processed for the first time, including Policy Agent starting
- A MODIFY PAGENT, REFRESH command is entered

NOFLUSH

Specifies that all policies installed in the Policy Agent and the TCP/IP stack are to remain during initial startup and at each refresh interval. In addition, policies that are deleted from a configuration are not deleted from the Policy Agent or the TCP/IP stack.

PURGE

Specifies that all policies installed in the TCP/IP stack are deleted during normal termination and when a TcpImage or PEPInstance statement is deleted.

NOPURGE

Specifies that no policies that are installed in the TCP/IP stack are deleted during normal termination and when a TcpImage or PEPInstance statement is deleted.

For details, see the [FLUSH and PURGE information](#) in [z/OS Communications Server: IP Configuration Guide](#).

Result: If the IDSConfig statement is deleted and the FLUSH parameter is configured, then all IDS configuration file policies are deleted from the corresponding stack.

IPSecConfig statement

Use the IPSecConfig statement to specify the path of a local IPSec policy file that contains stack-specific IPSec policy statements.

Specify the IPSecConfig statement without a path name in each image configuration file to define a common set of policies for multiple stacks.

Requirement: The IPSecConfig statement is required to define IPSec policy for a given stack.

The refresh interval for the IPSecConfig file is inherited from the image configuration file containing the corresponding IPSecConfig statement.

Results: For the associated TCP/IP image on the policy client, if the PolicyServer statement specifies remote IPSec policies, then the following occurs:

- If no local IPSec policies are installed, then the IPSecConfig statement is ignored.
- If local IPSec policies are already installed, the result is the same as if the IPSecConfig statement had been deleted.

Rule: For IPSec policies, when errors are detected during parsing, no new policies are installed.

The IpSecConfig statement can appear only in an image configuration file. If an IpSecConfig statement appears multiple times in an image configuration file, the last occurrence of the statement is used. If the IpSecConfig statement appears in the main configuration file, it is ignored (unless the main and image configuration files are the same file).

Syntax

➤ IpSecConfig — *path* ➤

Parameters

path

The path of the stack-specific IPsec policy file to be installed. If no path name is specified, then the common IPsec policy file specified on the CommonIpSecConfig statement is used.

You can specify an MVS data set name or a z/OS UNIX file name. MVS data set names must be enclosed in single quotation marks (' ') and preceded by a double slash (/). Following are examples of both types of names:

```
IPSecConfig // 'USER1.PAGENT.CONF(IPSEC) '
IPSecConfig /u/user1/pagent.ipsec
```

Restriction: Dynamic monitoring for file updates using the -i startup option is supported only for z/OS UNIX files; MVS data sets are not monitored for change.

Result: If the IPsecConfig statement is deleted, then all IPsec policies are deleted from the corresponding stack. The stack reverts to using the filter policy defined using the IPSEC statement in the TCP/IP profile. All IPsec policies for the stack are deleted from IKE.

LogLevel statement

Use the LogLevel statement to specify the level of tracing for the Policy Agent. use the trace records to help debug errors in policy definition.

Syntax

➤ LogLevel — *i* ➤

Parameters

i

An integer that specifies the level of logging and tracing. The following levels are supported:

- 1 - SYSERR - System error messages
- 2 - OBJERR - Object error messages
- 4 - PROTERR - Protocol error messages
- 8 - WARNING - Warning messages
- 16 - EVENT - Event messages
- 32 - ACTION - Action messages
- 64 - INFO - Informational messages
- 128 - ACNTING - Accounting messages
- 256 - TRACE - Trace messages

Usage notes

Use this statement to specify a desired log level or a combination of levels. If this statement is absent, the default level is 31.

To combine log levels, add log level numbers. For example, to request SYSERR messages (level 1) and EVENT messages (level 16), request log level 17.

Examples

The following example turns on all trace levels for Policy Agent:

```
LogLevel 511
```

PolicyPerfMonitorForSDR statement

Use the PolicyPerfMonitorForSDR statement to enable or disable the policy performance monitor function. This function assigns weight fractions to the monitored policy performance data and sends them to the sysplex distributor (SD) distributing stack as the monitored data crosses defined thresholds. The SD distributing stack uses these weight fractions to influence its routing decisions for incoming connection requests toward appropriate hosts within a group responsible for processing the requests. These connection requests are for a specific application (for example, HTTP web) for which one or more policies have been defined. For more information about [workload balancing](#), see [z/OS Communications Server: IP Configuration Guide](#).

Restriction: This statement applies only when policies are defined for the TCP protocol.

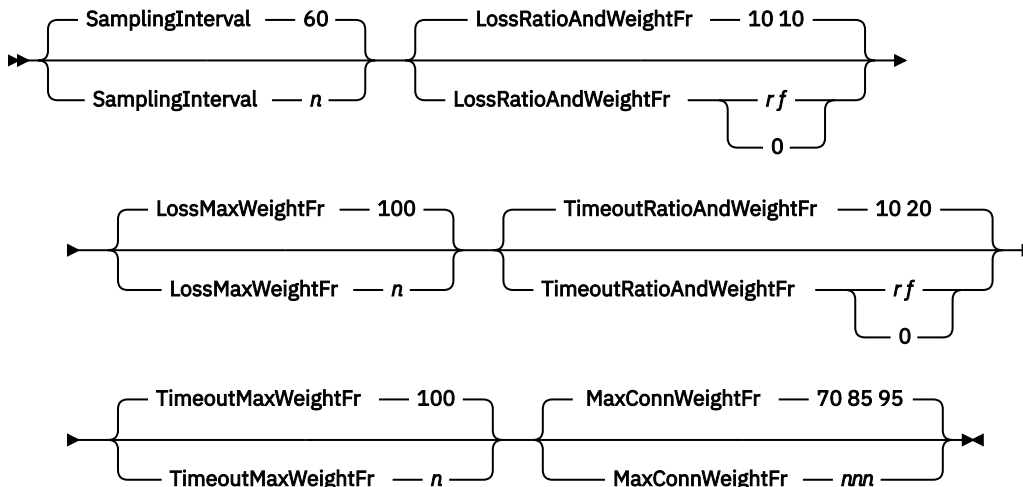

Syntax

Put Braces and Parameters on Separate Lines

PolicyPerfMonitorForSDR Parameters

Parameters

Enable | Disable

Enables or disables the policy performance monitor function. When active, this function monitors policy performance data on sysplex distributor target stacks and sends information to the Sysplex Distributor distributing stack to be used in balancing the workload among the target stacks. The policy performance data is based on statistics for traffic that maps to defined service policies.

The weight fractions determined for the loss ratio and timeout ratio are added together to form a single weight fraction before being sent to the SD distributing stack. One weight fraction is generated for each DVIPA/port pair on SD target stacks that have at least one policy defined that maps to traffic sent from the target DVIPA/port pair.

SamplingInterval

Specifies the interval in seconds for sampling policy performance data. The default is 60.

LossRatioAndWeightFr

Specifies two numbers. The first is the unit ratio of retransmitted bytes (loss) over transmitted bytes, in tenths of a percent (1 - 1 000). The second number is the weight fraction to be returned to the sysplex distributor distributing stack, in percentage (1 - 100). When present, this parameter results in creation of a threshold table. The first number defines the loss ratio initial threshold value. The second number defines the starting weight fraction that the sysplex distributor distributing stack is to use to reduce the WLM weight for this target stack. For example, if the weight fraction is 50% and the WLM weight is 64, then the resulting weight used for this target stack is 32. The LossMaxWeightFr parameter determines the maximum weight fraction that is reached. The default values for each number is 10. A weight fraction of 0 instructs the system to suppress the loss ratio factor in sysplex distributor computations.

Use the following formula to calculate the threshold table:

```
if x(n)% <= % Packet Loss < x(n+1)%, then weight fraction is y(n)%
```

x

Initial loss ratio percentage (first number)

y

Initial weight fraction (second number)

n

Integer multiplier

For example, if the first and second numbers are 10 and 10, then the threshold table is:

```
n=0 : 0% <= % packet loss < 1%; weight fraction is 0%
n=1 : 1% <= % packet loss < 2%; weight fraction is 10%
n=2 : 2% <= % packet loss < 3%; weight fraction is 20%
n=3 : 3% <= % packet loss < 4%; weight fraction is 30%
.
.
.
1(n)% <= % packet loss < 1(n+1)%; weight fraction is 10(n)%
```

If the first and second numbers are 30 and 20, then the threshold table is:

```
n=0: 0% <= % packet loss < 3%; weight fraction is 0%
n=1: 3% <= % packet loss < 6%; weight fraction is 20%
n=2: 6% <= % packet loss < 9%; weight fraction is 40%
n=3: 9% <= % packet loss < 12%; weight fraction is 60%
.
.
.
3(n)% <= % packet loss < 3(n)%; weight fraction is 20(n)%
```

Tip: These ratios are not only used as input to create the these weight fractions, but are also used to create the service level fractions. See [z/OS Communications Server: IP Configuration Guide](#) for more information about policy based networking.

LossMaxWeightFr

Specifies the maximum weight fraction to be assigned for the loss ratio factor. The default is 100 %.

TimeoutRatioAndWeightFr

Specifies two numbers. The first number is the unit ratio of the number of timeouts over transmitted packets, in tenths of a percent (1 - 1 000). The second number is the weight fraction to be returned to the sysplex distributor distributing stack, in percentage (1 - 100). When present, this parameter results in a creation of a threshold table. The first number defines the timeout ratio initial threshold value. The second number defines the starting weight fraction that the sysplex distributor distributing stack is to use to reduce the WLM weight for this target stack. For example, if the weight fraction is 50% and the WLM weight is 64, the resulting weight used for this target stack is 32. The maximum weight fraction reached is determined by the TimeoutMaxWeightFr parameter. The default values are 10 and 20. A weight fraction of 0 instructs the system to suppress the timeout ratio factor in sysplex distributor computations. See the LossRatioAndWeightFr parameter for more information about how the threshold table is calculated.

TimeoutMaxWeightFr

Specifies the maximum weight fraction to be assigned for the timeout ratio factor. The default is 100%.

MaxConnWeightFr

Specifies three percentages that are used in calculating the connection limit portion of the policy action (service level) weight fractions.

Restriction: Each percentage must be in the range 1 - 100, and each value must be greater than or equal to the preceding value.

The default values are 70, 85, and 95. When calculating the policy action weight fraction, the number of active connections to a target DVIPA/Port is compared with the maximum connections allowed for the associated policy action as follows:

- When the number of active connections reaches the percentage of maximum connections specified by the first number, the policy action weight fraction is set to MAX (50%, current calculated value).
- When the number of active connections reaches the percentage of maximum connections specified by the second number, the Policy Action weight fraction is set to MAX (85%, current calculated value).
- When the number of active connections reaches the percentage of maximum connections specified by the third number, the Policy Action weight fraction is set to 100%.

For more information about how the Policy Agent calculates policy action weight fractions, see [z/OS Communications Server: IP Configuration Guide](#).

Examples

In this example, Policy Agent sends a message to the SD distributing Stack when the loss (retransmission) ratio begins to exceed 1% but not above 2%, with a weight fraction of 20% . This means that the WLM weight is reduced by 20% before it is used as a measure to route incoming connection requests. When the loss (retransmission) ratio exceeds 2%, but not above 3%, a message is sent with a weight fraction of 40%, and so on. When the loss exceeds 5%, a maximum weight fraction of 100% is used. The same is true with the timeout ratio. When the timeout ratio exceeds 0.5%, but not above 1%, a weight fraction of 50% is added to the weight in the message sent to the SD distributing Stack, and so on.

```
PolicyPerfMonitorForSDR    Enable
{
  SamplingInterval          120
  LossRatioAndWeightFr      10    20
  LossMaxWeightFr           100
  TimeoutRatioAndWeightFr   5     50
  TimeoutMaxWeightFr        100
```

PolicyPerformanceCollection statement

Use the PolicyPerformanceCollection statement to enable or disable the policy performance collection function. Use this function to collect QoS performance monitoring data. The performance data can be collected on a policy rule or action or on both rules and actions. The collected data can also be logged to a specified performance log file for offline collection and monitoring by a user application, or can be accessed in near real time using the Policy API (PAPI).

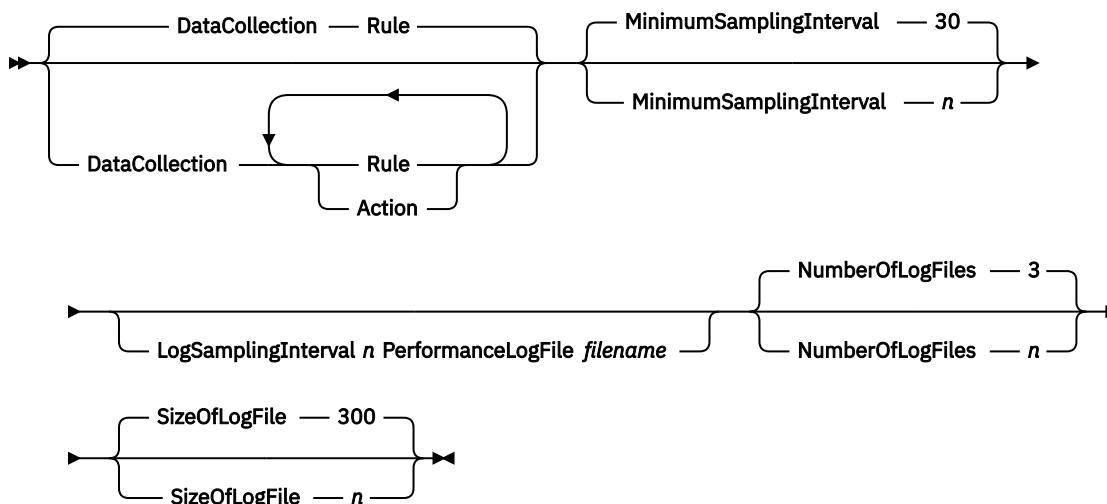

Syntax

Put Braces and Parameters on Separate Lines

PolicyPerformanceCollection Parameters

Parameters

Enable | Disable

Enables or disables policy performance collection. When active, this function collects the QoS performance data from the stack. The default is Disable.

DataCollection

Specifies the type of performance data that needs to be collected. The accepted values are:

Rule

To collect performance information for rules

Action

To collect performance information for actions.

Tip: Any combination of Rule, Action, or Rule Action can be used. If multiple types are used, separate them with a space (for example, Rule Action). The default value is Rule. The information returned for a policy action is an aggregate of the information for all the policy rules that use that policy action.

When FLUSH is specified on the TcpImage statement that defines the stack that is collecting performance data, the performance metrics are reset to 0 at the following times:

- When a new TcpImage statement is processed for the first time, including Policy Agent starting
- When a MODIFY PAGENT,REFRESH command is entered

If NOFLUSH is specified, the performance metrics are not reset.

MinimumSamplingInterval

Specifies the minimum sampling interval (in seconds) at which the performance data is retrieved from the stack. If the client, using the PAPI `papi_get_perf_data()` function, specified the `acceptableCachedTime` that is smaller than this value, the `acceptableCachedTime` value is overridden by `MinimumSamplingInterval`. See [z/OS Communications Server: IP Programmer's Guide and Reference](#) for more information about PAPI. The default value is 30 seconds. The values for `MinimumSamplingInterval` are in the range 30 - 2 147 483 647.

LogSamplingInterval

Specifies the log sampling interval in seconds at which the performance data is retrieved from the stack and logged into the log file defined by `PerformanceLogFile` parameter. The values for `LogSamplingInterval` are in the range 30 - 2 147 483 647.

Restriction: If `LogSamplingInterval` and `PerformanceLogFile` are not both specified, Policy Agent does not log the performance information.

PerformanceLogFile

Specifies the name of the file where collected performance data is written.

Restriction: If `LogSamplingInterval` and `PerformanceLogFile` are not both specified, Policy Agent does not log the performance information. This must be a z/OS UNIX file name. The file is created if it does not exist.

The `TcpImage` name for the stack for which this statement is configured is appended to the log file name, along with a numeric digit when `NumberOfLogFiles` is greater than 1. The format of the file name is `PerformanceLogFile.TcpImage.n`

For example, if `PerformanceLogFile` specified `/u/user10/perflog`, `NumberOfLogFiles` is 2, and `TcpImage` is `TCPCS`, the files is named:

```
/u/user10/perflog.TCPCS  
/u/user10/perflog.TCPCS.1
```

The data in the log file is in binary format. The format is as follows. See the descriptions of the output from the `NETSTAT SLAP` or `netstat -j` report in [z/OS Communications Server: IP System Administrator's Commands](#) for more detail on the meaning of the various fields. Also, see the `Network SLAPM2 MIB`, shipped as a sample file, for additional information about the performance data.

- 4-byte time stamp in `time_t` format, as output by the C `currentTime()` function, when the record was created
- 4-byte version identifier, as defined by `PCOL_LOG_VERSION` in the `papiuser.h` header file
- 48-byte policy name
- 4-byte record type
- 4-byte record ID
- 4-byte time stamp in `time_t` format, when the policy was last activated
- 4-byte time stamp in `time_t` format, when the policy was last mapped to any traffic
- 8-byte count of total bytes transmitted
- 8-byte count of total packets transmitted
- 4-byte count of active connections
- 4-byte reserved field
- 8-byte count of total accepted connections

- 4-byte average smoothed TCP round trip time (RTT)
- 4-byte mean deviation of smoothed TCP RTT
- 8-byte count of total bytes retransmitted
- 8-byte count of total packets retransmitted
- 4-byte average smoothed TCP connection delay
- 4-byte mean deviation of smoothed TCP connection delay
- 4-byte average TCP accept queue delay
- 4-byte mean deviation of TCP accept queue delay
- 8-byte count of total packets transmitted in profile
- 8-byte count of total bytes transmitted in profile
- 16-byte reserved field network slpa
- 8-byte count of total packets received
- 8-byte count of total bytes received
- 8-byte count of total retransmitted packets timed out
- 8-byte count of total denied connections
- 24-byte reserved field

NumberOfLogFiles

Specifies the number of performance log files to be maintained. The default value is 3. The values for NumberOfLogFiles are in the range 1 - 255. The log files are maintained in a round-robin fashion. When the current log file fills up, a new log file is created and all existing log files are renamed, with the oldest file being deleted if the total number of files would exceed the NumberOfLogFiles parameter. Each renamed file has a numeric digit added to the end of the name.

SizeOfLogFile

Specifies the log file size in kilobytes (Kb). The default value is 300 Kb. The values for SizeOfLogFile are in the range 1 Kb - 1 000 000 Kb.

The amount of data that fits in the log files, and therefore the amount of time that elapses before the files wrap, depends on a number of factors. Each performance data record is 232 bytes in length. You can use the following formulas:

- $\text{Size of log file in bytes} * \text{number of log files} / 232 = \text{number of records}$
- $\text{Number of records} / \text{number of policies} = \text{number of refresh cycles}$
- $\text{Number of refresh cycles} * \text{refresh interval in minutes} = \text{minutes worth of data}$

For example, assume 5 log files with a size of 400 kilobytes. Also, assume that only policy rule data is being collected, 25 policy rules exist, and the refresh interval is 120.

- $\text{Size of log file in bytes (409600)} * \text{number of log files (5)} / 232 = \text{number of records (8827)}$
- $\text{Number of records (8827)} / \text{number of policies (25)} = \text{number of refresh cycles (353)}$
- $\text{Number of refresh cycles (353)} * \text{refresh interval in minutes (2)} = 706 \text{ minutes worth of data}$

The previous formulas can be reversed to help arrive at the needed size of the log files:

- $\text{Number of refresh cycles} = \text{minutes worth of data} / \text{refresh interval in minutes}$
- $\text{Number of records} = \text{number of refresh cycles} * \text{number of policies}$
- $\text{Size of log file in bytes} = (\text{number of records} * 232) / \text{number of log files}$

PolicyServer statement

The Policy Agent acting as a policy client uses the PolicyServer statement to determine what type of policies to retrieve from the policy server. This statement also specifies security information and processing information that is passed to the policy server.

Requirement: Connectivity to the policy server is needed for all images that specify the PolicyServer statement.

Restriction: The PolicyServer statement can appear only in an image configuration file (unless the main and image configuration files are the same file).

Results:

- If a ServerConnection statement is not configured in the main configuration file, then this statement is ignored.
- For a policy type, if remote policies are used, then the local policies of the same type are ignored.
- The policy client disconnects from the policy server when one of the following occurs:
 - The ServerConnection or PolicyServer statement is removed. The result is that all remote policies are uninstalled. If local policies are configured, then they are installed.
 - The PolicyServer statement is updated and all PolicyType parameters are removed. The result is that the remote policies for the associated TCP/IP stack are uninstalled. If the local policies for the associated TCP/IP stack are configured, they are installed.
- The policy client disconnects from and reconnects to the policy server when one of the following occurs:
 - The PolicyServer statement is updated and the client name, user identification or authorization parameters have changed.
 - The connection between the policy server and the policy client ends.
- If a PolicyType parameter is removed, then the remote policies for this policy type are removed for the associated TCP/IP stack. If the local policies for this policy type are configured, they are installed.

You must have defined security product authority in the SERVAUTH class for the policy client's user ID. The policy client's client name is used as the image name. For details, see the [general policy agent configuration information in z/OS Communications Server: IP Configuration Guide](#). Wildcard values are allowed in profile names. The following example shows the structure of the security product profile:

```
EZB.PAGENT.sysname.image.ptype
```

If a PolicyServer statement appears multiple times in an image configuration file, the last occurrence of the statement is used. If the PolicyServer statement appears in the main configuration file, it is ignored (unless the main and image configuration files are the same file).

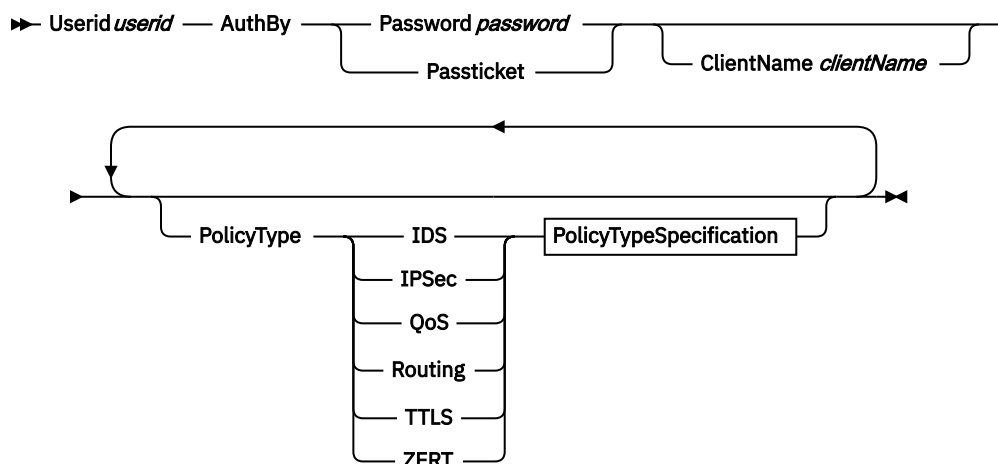

Syntax

➡ PolicyServer — Place Braces and Parameters on Separate Lines ➡

Place Braces and Parameters on Separate Lines

PolicyServer Parameters

PolicyTypeSpecification

PolicyTypeSpecification Parameters

Parameters

UserId

Specifies the policy client's user identification string. The policy server uses this parameter to identify which resources the client can access. The user ID is a string 1 - 8 alphanumeric characters in length. The first character cannot be a number. No special characters, such as the following, are allowed.

- at sign (@)
- dollar sign (\$)
- number sign (#)
- asterisk (*)

AuthBy

Indicates which method the policy server uses for authentication of the user ID. The options are Password and the more secure Passticket.

Password

This option causes the client to send the configured password to the policy server for authentication. The password is 1 - 8 characters in length.

Rule: The password must match the password defined in the security product for the user ID.

Passticket

The Passticket option causes the client to generate a one-time session key. See the information about the secured signon function in [z/OS Security Server RACF Security Administrator's Guide](#).

ClientName

A string 1 - 24 characters in length that specifies the client name (PEPInstance name) for this policy client. This client name is used by the policy server to determine which configuration files to use to load the client's policies and whether proper security authorization is configured. See ["DynamicConfigPolicyLoad statement" on page 855](#) for details about how this name is used to select the remote configuration file names.

Result: If no client name is configured, then the policy client generates this parameter based on the system's host name and the associated TcpImage or PEPInstance statement image name.

For example, if the system host name is MVSIBM and TcpImage name is TCPSC, then the generated client name is MVSIBM_TCPSC.

PolicyType

Indicates what policy types the policy client retrieves from the policy server.

Results:

- If you specify the policy type IPsec, but IPsec policies are not enabled for the client's TCP/IP stack, then this parameter is ignored. This means that no IPsec policies are retrieved from the policy server. To enable IPsec in the TCP/IP stack, use the IPSECURITY parameter on the IPCONFIG statement in the TCP/IP profile.
- If you specify the policy type ZERT, but the policy server is at V2R4 or earlier, this parameter is ignored. This means that no ZERT policies are retrieved from the policy server.

FLUSH

Specifies that all policies installed in the Policy Agent and the TCP/IP stack are deleted at the following times:

- When a new TcpImage statement is processed for the first time, including starting Policy Agent.
- When a MODIFY PAGENT,REFRESH command is entered.

NOFLUSH

Specifies that all policies installed in the Policy Agent and the TCP/IP stack are to remain during initial startup and at each refresh interval. In addition, policies that are deleted from a configuration are not deleted from the Policy Agent or the TCP/IP stack.

PURGE

Specifies that all policies installed in the TCP/IP stack are deleted during normal termination, and also when a TcpImage or PEPInstance statement is deleted.

NOPURGE

Specifies that all policies installed in the TCP/IP stack remain during normal termination and when a TcpImage or PEPInstance statement is deleted.

For details, see the [FLUSH and PURGE information](#) in *z/OS Communications Server: IP Configuration Guide*.

Results:

- The FLUSH, NOFLUSH, PURGE, and NOPURGE parameters are ignored for the policy types IPsec, Routing, and ZERT.
- To delete all remote policies for a given policy type, delete the appropriate PolicyType parameter from the PolicyServer statement. This deletes these policies from the policy client and the policy server.

QOSConfig statement

Use the QOSConfig statement to specify the path of a local QoS policy file that contains stack-specific QoS policy statements.

Results: For the associated TCP/IP image on the policy client, if the PolicyServer statement specifies remote QoS policies, then one of the following situations occurs:

- If no local QoS policies are installed, then the QOSConfig statement is ignored.
- If local QoS policies are already installed, the result is the same as if the QOSConfig statement had been deleted.

The refresh interval for the QOSConfig file is inherited from the image configuration file containing the corresponding QOSConfig statement.

The QOSConfig statement can appear only in an image configuration file. If a QOSConfig statement appears multiple times in an image configuration file, the last occurrence of the statement is used. If the QOSConfig statement appears in the main configuration file, it is ignored (unless the main and image configuration files are the same file).

Syntax

➤ QOSConfig — *path* ➤

Parameters

path

The path of the stack-specific QOS policy file to be installed.

You can specify an MVS data set name or a z/OS UNIX file name. MVS data set names must be enclosed in single quotation marks (' ') and preceded by a double slash (/). Following are examples of both types of names:

```
QOSConfig // 'USER1.PAGENT.CONF(QOS) '  
QOSConfig /u/user1/pagent.qos
```

Restriction: Dynamic monitoring for file updates using the `-i` startup option is supported only for z/OS UNIX files; MVS data sets are not monitored for change.

Results:

- If the QOSConfig statement is not specified, then QoS policies are defined in the image configuration file.
- If the QOSConfig statement is deleted and FLUSH is configured, then all QoS policies that are defined in this QoS policy file are deleted from the corresponding stack.

ReadFromDirectory statement

Use the ReadFromDirectory statement to initialize Policy Agent as an LDAP client. The policies are downloaded from the LDAP server, along with the policies specified in this Policy Agent configuration file (the current one being used by Policy Agent that contains this statement). All the policies are installed to the appropriate TCP images.

You can use a set of sample files to help set up the LDAP server and populate it with policies. These files reside in the `/usr/lpp/tcpip/samples` directory.

One set of sample files defines the schema object classes and attributes for LDAP protocol version 3 servers. These files are:

- `pagent_r8qosschema.ldif`
- `pagent_r5idsschema.ldif`

Requirement: These files must be installed on the LDAP server as a subschema of the `cn=schema` object by using the command.

See the prologs in these sample files and [z/OS Communications Server: IP Configuration Guide](#) for more information.

The remaining sample files are examples of policy objects that can be installed on an LDAP server after the schema has been defined using this schema definition files. These files are:

- `pagent.ldif` contains a top level structure of policy objects.
- `pagent_starter_IDS.ldif` contains a starter set of IDS policies.
- `pagent_starter_QoS.ldif` contains a starter set of QoS policies.
- `pagent_advanced_IDS.ldif` contains an advanced set of IDS policies.

- `pagent_advanced_QoS.ldif` contains an advanced set of QoS policies.

See the prologs in these sample files and [z/OS Communications Server: IP Configuration Guide](#) for more information.

Tip: These policies are not intended to be used as shipped, but they can be copied to a *custom* set (defined in `pagent.ldif`) and modified as needed.

For more information about how to use LDAP and for other LDAP references, see *Understanding LDAP (SG24-4986)*.

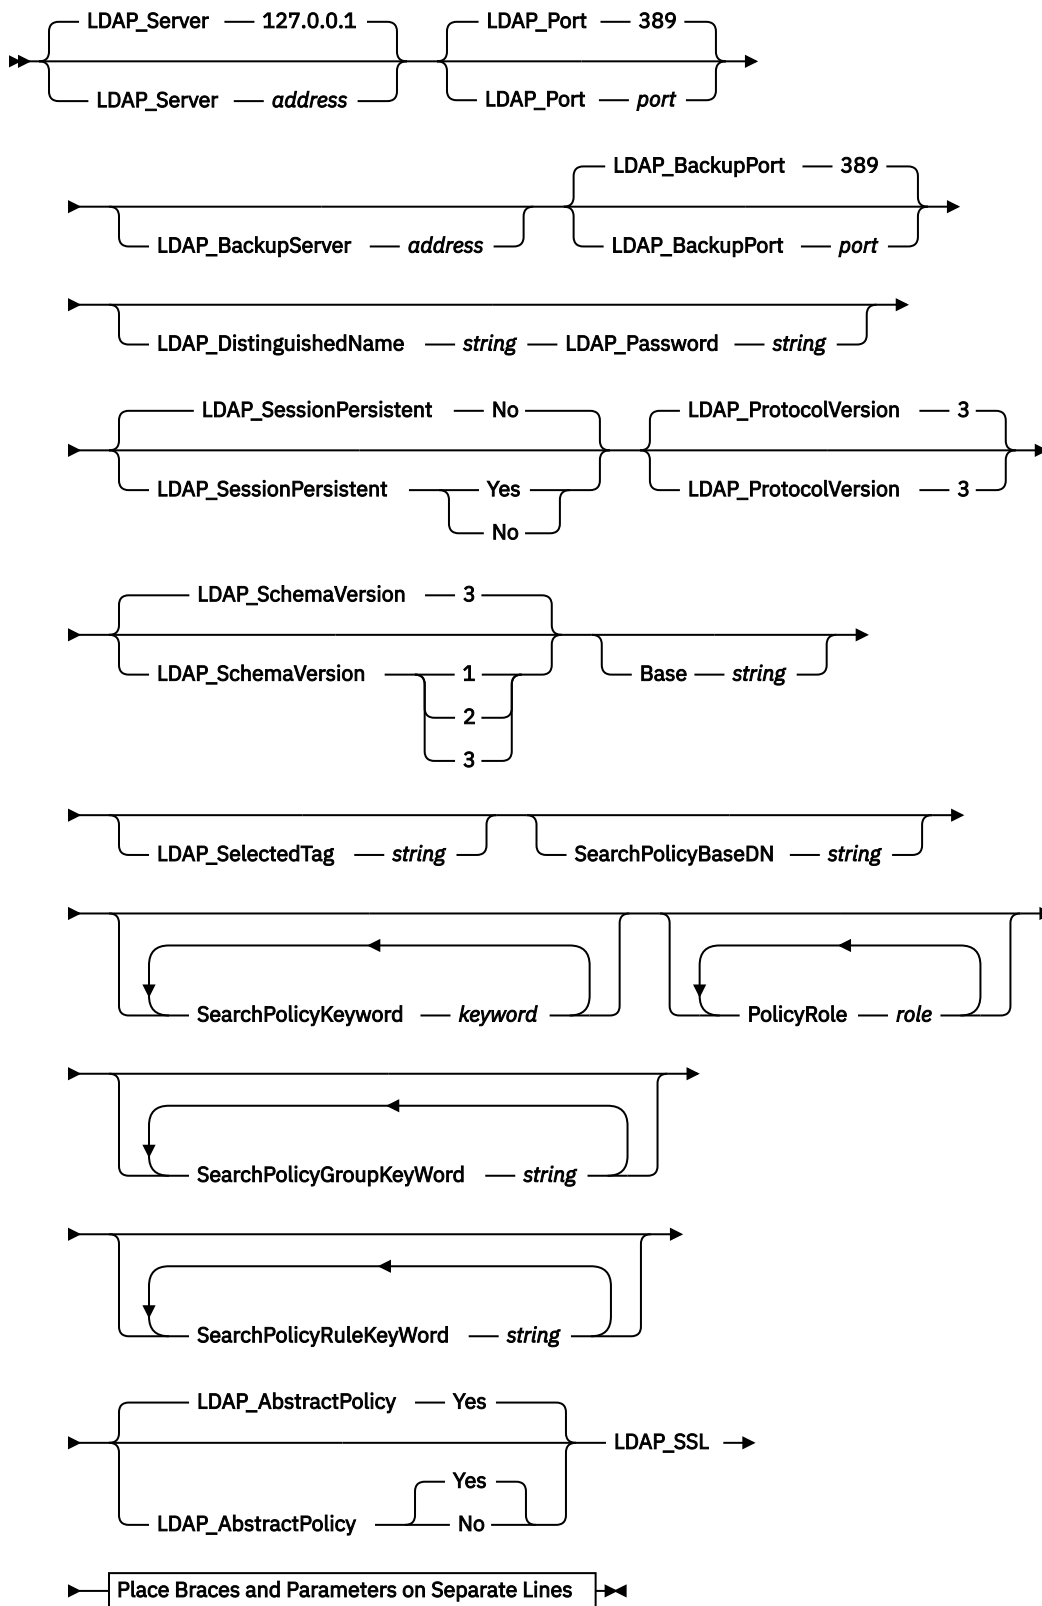

Syntax

➤➤ ReadFromDirectory — Place Braces and Parameters on Separate Lines ➤➤

Place Braces and Parameters on Separate Lines

ReadFromDirectory Parameters

Place Braces and Parameters on Separate Lines

LDAP_SSL Parameters

Parameters

LDAP_Server

The name of the server that contains policy definitions. The name can be specified as a character string (for example, 'ldapserv.mynetwork.com') or as an IPv4 address (for example, 9.11.12.13). The default is the LDAP server in the local host (127.0.0.1).

LDAP_Port

The port on which the directory server is running. If not specified, the default, well-known LDAP port of 389, is used.

LDAP_BackupServer

This attribute specifies the name or IPv4 address of the backup LDAP server for which the search is performed if the Policy Agent cannot connect to the LDAP server as specified in the LDAP_Server and LDAP_Port parameters. The default is no backup server.

LDAP_BackupPort

This attribute specifies the port number on which the backup LDAP server is running. The default is the well-known LDAP port 389.

LDAP_DistinguishedName

This attribute is a character string value that specifies the distinguished name for user ID to connect to the LDAP server. If this attribute is not specified, anonymous user ID is used for the connect. If this attribute is specified, LDAP_Password must also be specified.

Restriction: Case sensitivity of this attribute is determined by the LDAP server.

LDAP_Password

The password of the connection to the LDAP server. If this attribute is specified, LDAP_DistinguishedName must also be specified.

LDAP_SessionPersistent

A string that specifies whether the LDAP session with the directory server should be kept open or closed during an update interval time. If this value is not specified, the session is closed after every query from the directory server. Valid values are yes or no. If the LDAP session update interval is small, the value of keeping the session open is greater, because it reduces the overhead of opening the session for each query.

LDAP_ProtocolVersion

This attribute indicates to Policy Agent what version of the LDAP protocol to use. The default value is 3.

LDAP_SchemaVersion

This attribute indicates to Policy Agent what version of the schemas to retrieve from LDAP. The value can be 1, 2, or 3. The value should be selected based on your LDAP configuration. The default value is 3.

Base

The distinguished name of the subtree in the directory containing the policies.

Requirement: This is required when using schema Version 1 only.

LDAP_SelectedTag

A string used to select a subset of the policies under the base tree. If not specified, the first machine name returned by gethostname is used.

Restriction: This is allowed only when using schema Version 1.

SearchPolicyBaseDN

This attribute is a character string value (a base distinguished name) that is used as a key to search the LDAP server for policies. It is considered as the initial subtree/group/object to start the search.

Requirement: This attribute is only allowed, and is required, if LDAP_SchemaVersion 2 or higher is specified.

Guideline: Case-sensitivity of this attribute is determined by the LDAP server.

SearchPolicyKeyword

This attribute specifies a generic search keyword to match against all policy objects. Use this attribute to filter the policy objects to be retrieved.

Restriction: This attribute is valid only with LDAP_SchemaVersion 3.

You can specify up to eight instances of this attribute. Specify either a single keyword delimited by blanks or any string containing blanks or other special characters, contained in double quotation marks. For example:

```
SearchPolicyKeyword    singleword
SearchPolicyKeyword    "quoted string"
```

SearchPolicyGroupKeyWord

This attribute is a character string value used to scope the search for all group objects.

Restrictions:

- Only policy groups that have a matching PolicyGroupKeywords attribute are returned in the initial search.
- This attribute is allowed only if LDAP_SchemaVersion 2 or higher is specified.

This is similar to the LDAPSelectedTag attribute that is used with LDAP_SchemaVersion 1.

Guidelines:

- Up to eight instances of this attribute are allowed.
- Case-sensitivity of this attribute is determined by the LDAP server.

SearchPolicyRuleKeyWord

This attribute is a character string value that allows users to limit the scope of the policyRule search.

Restrictions:

- Only policy rules that have a matching policyRuleKeywords attribute are returned in the initial search.
- This attribute is allowed only if LDAP_SchemaVersion 2 or higher is specified.

This attribute can also be used when there is no group association in the LDAP server (for example, there is no group hierarchy defined, only rule objects exist) for the policyRule objects.

Guidelines:

- Up to eight instances of this attribute are allowed.
- Case-sensitivity of this attribute is determined by the LDAP server.

PolicyRole

Specifies a policy role or role-combination. Use this parameter to filter the policy rules to be retrieved.

Restriction: This parameter is valid only with LDAP_SchemaVersion 3.

Guidelines:

- This parameter can be repeated as many times as necessary.
- Either a single role or a set of roles, known as a role-combination, can be specified.
- The roles can be single words, or any strings containing blanks or other special characters, contained in double quotation marks.

Role-combinations are specified as follows. The first role is specified the same way that a single role is specified. Each additional role in the role-combination is prefixed with the characters &&. For example:

```
PolicyRole    role1
PolicyRole    &&"quoted role 2"
PolicyRole    "quoted role 3"
PolicyRole    role4
```

Use this parameter to filter out policy rules that do not contain any of the specified roles or role-combinations, using the attribute `ibm-policyRoles`. For example, the set of roles specified in this example result in the retrieval of any policy rules that specify "role1&"ed role 2" or "quoted role3" or "role4" in their `ibm-policyRoles` values.

LDAP_AbstractPolicy

Specifies whether or not the Policy Agent should search the LDAP server using a search filter that only selects *policy* object classes. Valid values are YES or NO, and YES is the default. If the LDAP server supports matching of auxiliary classes for the objectClass attribute, specify YES. Otherwise, specify NO. This attribute is valid only with LDAP_SchemaVersion 3 and LDAP protocol version 3.

LDAP_SSL

Indicates that additional SSL parameters follow.

LDAP_SSLKeyringFile

LDAP_SSLKeyringFile is the name of the key ring file created by gskkyman. It usually contains the certificates of the trusted (by the client) Certificate Authorities. It can also contain a public key and the associated certificate.

Restriction: This is only needed when client authentication is required.

This attribute is required when LDAP_SSL is specified.

LDAP_SSLKeyringPassword

LDAP_SSLKeyringPassword is the password which protects the key ring file. It is set when the key ring file is created with the gskkyman tool.

LDAP_SSLName

LDAP_SSLName is a case-sensitive value that specifies the label assigned when creating a private key/certificate pair with gskkyman. This is used when the client is authenticated.

Restriction: Some servers do not support client authentication; therefore, this parameter is not used.

Examples

The following is a Version 1 schema example:

```
ReadFromDirectory
{
    Ldap_server      ldapserver.mynetwork.com
    Ldap_port        9000
    Base             o=ibm,c=us
    Ldap_selectedtag MVS1
}
```

The following is a Version 2 schema example:

```
ReadFromDirectory
{
    LDAP_Server 9.11.12.13
    LDAP_Port 9000
    LDAP_SessionPersistent Yes
    LDAP_BackupServer 9.11.22.23
    LDAP_BackupPort 555
    LDAP_DistinguishedName cn=root, o=IBM, c=US
    LDAP_Password secret
    LDAP_SchemaVersion 2
    LDAP_ProtocolVersion 3
    SearchPolicyBaseDN o=ibm, c=us
    SearchPolicyGroupKeyword MVSA
    SearchPolicyRuleKeyword cherryPicker
}
```

```

    SearchPolicyRuleKeyword ripe
}

```

The following is a Version 3 schema example:

```

ReadFromDirectory
{
    LDAP_Server ldapv3server
    LDAP_BackupServer 10.100.1.5
    LDAP_BackupPort 7500
    LDAP_DistinguishedName cn=root, o=IBM, c=US
    LDAP_Password secret
    LDAP_SchemaVersion 3
    LDAP_ProtocolVersion 3
    LDAP_AbstractPolicy Yes
    SearchPolicyBaseDN cn=policy, o=ibm, c=us
    SearchPolicyKeyword QoS
    SearchPolicyKeyword Diffserv
}

```

RoutingConfig statement

Use the RoutingConfig statement to specify the path of a local Routing policy file that contains stack-specific Routing policy statements.

Requirement: The RoutingConfig statement is required to define Routing policy for a given stack.

Result: For the associated TCP/IP image on the policy client, if the PolicyServer statement specifies remote Routing policies, then the following occurs:

- If no local Routing policies are installed, then the RoutingConfig statement is ignored.
- If local Routing policies are already installed, then the result is the same as if the RoutingConfig statement had been deleted.

Specify the RoutingConfig statement without a path name in each image configuration file to define a common set of policies for multiple stacks.

The refresh interval for the RoutingConfig file is inherited from the image configuration file containing the corresponding RoutingConfig statement.

Restriction: The RoutingConfig statement can appear only in an image configuration file.

If a RoutingConfig statement appears multiple times in an image configuration file, the last occurrence of the statement is used. If the RoutingConfig statement appears in the main configuration file, it is ignored (unless the main and image configuration files are the same file).

Syntax

```

➔ RoutingConfig ——— path —➔

```

Parameters

path

Specifies the path of the stack-specific Routing policy file to be installed. If no path name is specified, the common Routing policy file specified on the CommonRoutingConfig statement is used.

You can specify an MVS data set name or a z/OS UNIX file name. MVS data set names must be enclosed in single quotation marks (' ') and preceded by a double slash (/). Following are examples of both types of names:

```

RoutingConfig  //'USER1.PAGENT.CONF(ROUTING)'
RoutingConfig  /u/user1/pagent.routing

```

Restriction: Dynamic monitoring for file updates using the `-i` startup option is supported only for z/OS UNIX files; MVS data sets are not monitored for changes.

Results:

- After a TCP/IP stack has been recycled, all active policies are reinstalled.
- If the RoutingConfig statement is deleted, all Routing policies are deleted from the corresponding stack.

ServerConnection statement

The Policy Agent acting as a policy client uses the ServerConnection statement to connect to the Policy Agent acting as a policy server. This statement includes security information and the location of the policy server. The policy client uses this connection to retrieve remote policies. See [“PolicyServer statement” on page 869](#) for more details.

Results:

- An error is flagged if both the ClientConnection and ServerConnection statements are configured on the same Policy Agent. As a result, there is no connection between the policy server and policy client.
- If a PolicyServer statement is not configured in any image configuration file, this statement is ignored, and no connections to the policy server exist.
- If any parameters on the ServerConnection statement are updated after a remote connection is established, the changed values take effect for new connections. The ServerConnectWait and ServerConnectRetries parameters take effect immediately for any connections that require retry processing.
- If the ServerConnection statement is deleted, all established remote connections are stopped. As a result, all remote policies are uninstalled. If configured, then the local policies are now installed.

Syntax

►► ServerConnection — Place Braces and Parameters on Separate Lines ◄◄

Place Braces and Parameters on Separate Lines

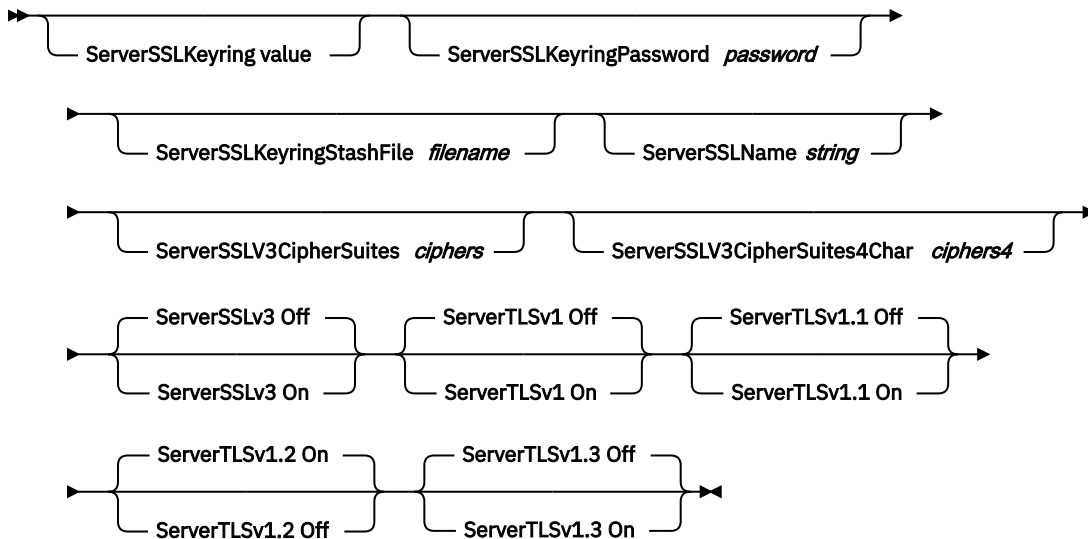

ServerConnection Parameters

ServerSSL Specification

ServerSSL Parameters

Parameters

ServerHost

A string 1 - 512 characters in length that specifies the name of the primary policy server host that contains policy definitions. Specify the name as a host name (for example, policyserver.mynetwork.com) or as an IP address (for example, 9.11.12.13). The IP address can be either IPv4 or IPv6. This parameter is required.

ServerPort

The policy server listening port number. The policy client connects using this port number.

The valid port values are in the range 1 - 65 535. The default is 16 310.

ServerHostBackup

A string 1 - 512 characters in length specifying the name of the backup policy server that contains policy definitions. The name can be specified as a host name (for example, policyserver.mynetwork.com) or as an IP address (for example, 9.11.12.13). The IP address can be either IPv4 or IPv6. The default is no backup server.

ServerPortBackup

The backup policy server listening port number. The policy client connects using this port number.

The valid port values are in the range 1 - 65 535. The default is 16 310.

Result: This parameter is ignored if the ServerHostBackup parameter is not specified.

ServerConnectWait

Specifies the number of seconds (1-300) that the policy client waits between connection attempts when trying to establish a connection with a policy server. The default value is 60 seconds.

The product of the ServerConnectWait value multiplied by the ServerConnectRetries value defines the maximum number of seconds that the policy client attempts to connect with a policy server before switching to another policy server (if a backup server is configured). For example, if the ServerConnectWait value is 60 and the ServerConnectRetries value is 3, then the policy client waits a maximum of 180 seconds for a successful connection.

This parameter is also used if policies cannot be loaded from the policy server. The policy client waits for the specified amount of time before trying to load the policies again.

ServerConnectRetries

Specifies the number of times (1-10) that the policy client attempts to establish a connection with a policy server. The default value is 3 retries.

The product of the ServerConnectWait value multiplied by the ServerConnectRetries value defines the maximum number of seconds that the policy client attempts to connect with a policy server before switching to another policy server (if a backup server is configured) . For example, if the ServerConnectWait value is 60 and the ServerConnectRetries value is 3, then the policy client waits a maximum of 180 seconds for a successful connection.

ServerSSL

Indicates that additional TLS/SSL parameters follow.

This parameter is optional. If you want to use a secure connection to the policy server, specify this parameter and other TLS/SSL parameters as needed.

If ServerSSL is specified, only TLSv1.2 is enabled by default. You can choose to enable TLSv1.1, TLSv1, or SSLv3 but should only do so if the policy server is unable to support a later TLS version

You can choose whether to enable TLSv1.3 with the ServerTLSv1.3 parameter. If it is enabled, the supported ciphers must be explicitly configured also. See details under the ServerTLSv1.3 parameter description.

ServerSSLKeyring

A string 1 - 1023 characters in length specifying the name of the key database file created by gskkyman, or the ring name of the SAF key ring. A SAF key ring is specified as *userid/keyring*. The *userid* must be the z/OS user ID that owns the keyring. If *userid* is not specified, the user ID under which the Policy Agent is executing will be used.

This key ring usually contains the certificates of the trusted (by the client) Certificate Authorities. The key ring can also contain a public key and the associated certificate (this is needed only when client authentication is required).

This parameter is required if ServerSSL is specified.

ServerSSLKeyringStashFile

A string 1 - 1023 characters in length that specifies the name of the key database stash file. The stash file is created when the key ring file is created with the gskkyman tool. If the ServerSSLKeyringPassword parameter is specified, then it is used instead of this parameter. The password and the stash file parameter are not required with a SAF keyring.

ServerSSLKeyringPassword

A string 1 - 128 characters in length that specifies the password for the key database file created with the gskkyman tool. This parameter is optional. As an alternative, you can specify the more secure ServerSSLKeyringStashFile parameter to use a key database that was created with the gskkyman tool. The password and the stash file parameter are not required with a SAF key ring.

ServerSSLName

A string 1 - 256 characters in length specifying a case-sensitive value that specifies the label assigned when creating a private key/certificate pair with gskkyman. This value is used when the client is authenticated.

Rules (for servers that use client authentication:

- If the AT-TLS policy on the policy server specifies HandshakeRole Server, the ServerSSLName parameter must specify the name of the server's certificate.
- If the AT-TLS policy on the policy server specifies HandshakeRole ServerWithClientAuth, the ServerSSLName parameter must specify the name of the client's certificate.

Restriction: Some servers do not support client authentication; therefore, this parameter is not used.

ServerSSLV3CipherSuites

Tip: If the System SSL needs to access z/OS Integrated Cryptographic Services Facility (ICSF), ICSF must be started before you start the Policy Agent. For more information about using hardware Cryptographic Features with System SSL, see [z/OS Cryptographic Services System SSL Programming](#).

Specifies the SSLv3 or TLSv1 cipher suites in order of preference. If a `ServerSSLV3CipherSuites` or `ServerSSLV3CipherSuites4Char` parameter is specified more than once, the values are concatenated to create a single list of cipher suites. For System SSL, the `GSK_V3_CIPHER_SPECS_EXPANDED` value is set to the concatenated value.

The *ciphers* value is a string of one or more 2-hexadecimal character SSLv3 or TLSv1 ciphers, or a single cipher constant. The cipher string cannot have blanks between each cipher. If duplicate ciphers, the first instance of the cipher is used and all other instances you specify are ignored. The maximum number of ciphers is 255. For System SSL, see [Cipher suite definitions in z/OS Cryptographic Services System SSL Programming](#) for a list of valid cipher suites. [Table 72 on page 883](#) lists cipher constants that are supported.

<i>Table 72. Supported cipher constants for the <code>ServerSSLV3CipherSuites</code> parameter</i>		
Cipher constant	Hexadecimal character	Expanded character
TLS_NULL_WITH_NULL_NULL	00	0000
TLS_RSA_WITH_NULL_MD5	01	0001

TLS_ECDH_ECDSA_WITH_AES_256_GCM_SHA384		C02E
TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256		C02F
TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384		C030
TLS_ECDH_RSA_WITH_AES_128_GCM_SHA256		C031
TLS_ECDH_RSA_WITH_AES_256_GCM_SHA384		C032

ServerSSLV3CipherSuites4Char

Tip: If System SSL needs to access z/OS Integrated Cryptographic Services Facility (ICSF), ICSF must be started before you start the Policy Agent. For more information about using hardware Cryptographic Features with System SSL, see [z/OS Cryptographic Services System SSL Programming](#).

Specifies the SSLv3 or TLSv1 cipher suites in order of preference. If a ServerSSLV3CipherSuites or ServerSSLV3CipherSuites4Char parameter is specified more than once, the values are concatenated to create a single list of cipher suites. For System SSL, the GSK_V3_CIPHER_SPECS_EXPANDED value is set to the concatenated value.

The *ciphers4* value is a string of one or more 4-hexadecimal (expanded) character SSLv3 or TLSv1 ciphers. The cipher string does not recognize cipher constants and cannot have blanks between each

cipher. If there are duplicate ciphers, the first instance of the cipher is used and all other instances you specify are ignored. The maximum number of ciphers is 255. For System SSL, see [Cipher suite definitions in z/OS Cryptographic Services System SSL Programming](#) for a list of valid cipher suites.

ServerSSLv3

Indicates whether SSLv3 is enabled for the policy client that connects to the server.

On

SSLv3 is enabled.

Off

SSLv3 is disabled. This is the default.

ServerTLSv1

Indicates whether TLSv1 is enabled for the policy client that connects to the server.

On

TLSv1 is enabled.

Off

TLSv1 is disabled. This is the default.

ServerTLSv1.1

Indicates whether TLSv1.1 is enabled for the policy client that connects to the server.

On

TLSv1.1 is enabled.

Off

TLSv1.1 is disabled. This is the default.

ServerTLSv1.2

Indicates whether TLSv1.2 is enabled for the policy client that connects to the server.

On

TLSv1.2 is enabled. This is the default.

Off

TLSv1.2 is disabled.

ServerTLSv1.3

Indicates whether TLSv1.3 is enabled for the policy client that connects to the server.

On

TLSv1.3 is enabled.

Off

TLSv1.3 is disabled. This is the default.

Requirement: If TLSv1.3 is enabled:

- At least one cipher supported for TLSv1.3 must be specified on the `ServerSSLV3CipherSuites` or `ServerSSLV3CipherSuites4Char` parameter.
- At least one cipher supported for earlier versions of TLS must be specified on the `ServerSSLV3CipherSuites` or `ServerSSLV3CipherSuites4Char` parameter.

For a list of cipher suite definitions by supported protocol, see [Cipher suite definitions in z/OS Cryptographic Services System SSL Programming](#).

ServicesConnection statement

The Policy Agent uses the `ServicesConnection` statement to specify the listening port, listening TCP/IP image, and security level for connections to the Policy Agent. Applications that use this connection are known as services requestors. One such services requestor is the IBM Configuration Assistant for z/OS Communications Server, which is an import requestor that uses this connection to retrieve TCP/IP interface information for use by IPSec technology.

Consider the following characteristics when using the ServicesConnection statement:

- If you want to use default values for all parameters, you can specify the ServicesConnection statement without a set of braces.
- If you specify Security Basic, you can either use a default unsecure connection or supply user defined AT-TLS policies for this service connection to create a secure SSL connection.
- If you specify Security Secure, the Policy Agent generates an AT-TLS policy and installs it at the lowest priority (lower than any configured policies) into the specified TCP/IP image after any configured local or remote AT-TLS policies have been installed.

Tip: For secure SSL, it is recommended to configure Security Basic and to supply user defined AT-TLS policies to protect the service connection with the required SSL/TLS protection. The AT-TLS policies generated with the Security Secure option do not use the strongest TLS protocol levels.

- If you update any parameters that are used in the generated policy (Port, Trace or Keyring parameters), the Policy Agent reinstalls the generated policy.
- The Policy Agent listens for TCP connections on the specified TCP/IP image name only.
- If you remove the ServicesConnection statement, all services requestor connections to this Policy Agent are disconnected.
- Updates to the ServicesConnection statement are used for only new services requestor connections to the Policy Agent.
- If you do not configure the ServicesConnection statement, or the image name is not an active TCP/IP image, the Policy Agent does not listen on any port for services requestor connections.
- To restart the listen for services requestor connections and to reinstall the generated AT-TLS policy, issue the MODIFY SRVLSTN command. See [z/OS Communications Server: IP System Administrator's Commands](#) for more information about this command.

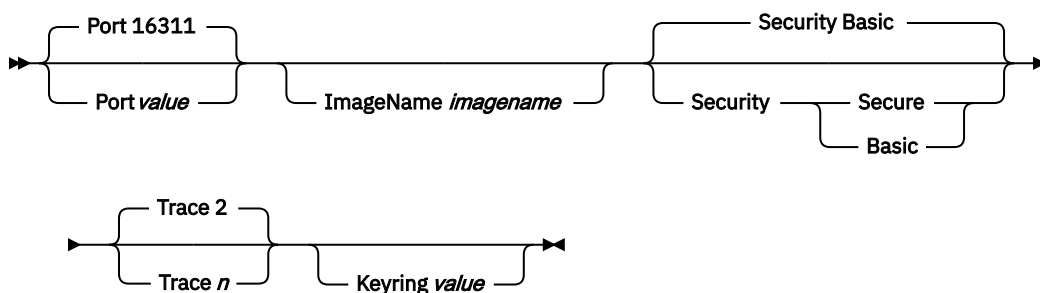

Syntax

►► ServicesConnection — Place Braces and Parameters on Separate Lines ◄◄

Place Braces and Parameters on Separate Lines

ServicesConnection Parameters

Parameters

Port

Specifies the port that the Policy Agent listens on for TCP connections from services requestors on the specified TCP/IP image name. If you are using the IBM Configuration Assistant for z/OS Communications Server, this port must be the same as the host connection port that is specified on

the IBM Configuration Assistant for z/OS Communications Server on the request panels for discovery import (for example, on the Discover Stack Local Addresses panel).

If you change the Port parameter value, the Policy Agent listens for new TCP connections using the updated value on the specified TCP/IP image name.

Valid port values are in the range 1 - 65 535. The default port value is 16 311.

Restriction: The port value cannot match the port value configured on the ClientConnection statement.

ImageName

A string 1 - 8 characters in length that specifies the TCP/IP image name. The Policy Agent listens for services connections only on this TCP/IP image.

If you change the ImageName value, the Policy Agent listens for new TCP connections on the newly specified TCP/IP image name. If you specify the Security parameter with the Secure value and update the ImageName parameter, the Policy Agent removes the generated policy from the original TCP/IP image and installs it on the newly specified image.

If you specify Security Basic and define AT-TLS policies for this service connection to create a secure SSL connection, these policies must be installed for this ImageName.

Results:

- In a single stack (INET) environment, the Policy Agent uses the active TCP/IP image to listen for services connection requests.
- In a common INET (CINET) environment, if you do not specify the TCP/IP image name, the Policy Agent uses the default TCP/IP image (resolver supplied TCPIPuserid statement or TCPIPjobname statement). If the Policy Agent cannot determine the default TCP/IP image, the Policy Agent uses the name INET.
- If you specify an image name that does not have a corresponding TcpImage or PEPInstance statement, the Policy Agent creates an internal TcpImage statement with default values to represent the specified TCP/IP image. You can specify only 7 (instead of 8) TcpImage or PEPInstance statements.
- If you specify an image name that is not active, the Policy Agent does not listen for services requestor connections until the TCP/IP image becomes active.

Security

Indicates the level of security that is used for the services requestor connection. If you change the Security parameter from Secure to Basic, the Policy Agent uninstalls the generated AT-TLS policy from the specified TCP/IP image.

Basic

Specifies one of the following connections:

- The connection does not use SSL and is unsecure.
- You define AT-TLS policies for this service connection to create a secure SSL connection.

Result: If you specify the Security Basic setting without defining AT-TLS policies, the user ID and password that the services requestor provides flow without encryption.

Tip: For secure SSL, it is recommended to configure Security Basic and to supply user defined AT-TLS policies to protect the service connection with the required SSL/TLS protection.

Secure

Specifies that the connection uses SSL. The Policy Agent installs a generated AT-TLS policy similar to the following example into the specified TCP/IP image to protect the connection.

Restriction: This option supports only TLSv1.0 and TLSv1.1 and is not recommended for secure SSL.

```
TTLSRule
{
    LocalPortRange          TTLS_RULE_____GENERATED
                           <ServicesConnection port value>
```

```

        Direction
        TTLSGroupActionRef      Inbound
        TTLSGroupActionRef      TTLS_GROUP_ACTION_____GENERATED
        TTLSEnvironmentActionRef TTLS_ENVIRONMENT_ACTION_GENERATED
    }
    TTLSGroupAction      TTLS_GROUP_ACTION_____GENERATED
    {
        TTLSEnabled      On
        Trace             <ServicesConnection trace value>
    }
    TTLSEnvironmentAction TTLS_ENVIRONMENT_ACTION_GENERATED
    {
        HandshakeRole      Server
        TTLSKeyRingParms
        {
            Keyring         <ServicesConnection keyring value>
        }
    }
}

```

Rule: If you specify Security Secure, the Keyring parameter is required.

Trace

Specifies the level of AT-TLS tracing to be used for the generated AT-TLS policy. Valid values for *n* are in the range 0 - 255. The sum of the numbers associated with each level of selected tracing is the value you should specify for *n*. If *n* is an odd number, errors are written to joblog, and all other configured traces are sent to syslogd.

0

No tracing is enabled.

1 (Error)

Errors are traced to the TCP/IP joblog.

2 (Error)

Errors are traced to syslogd. This is the default. The messages are issued with syslogd priority code **err**.

4 (Info)

Enables tracing of instances when a connection is mapped to an AT-TLS rule and when a secure connection is successfully initiated. The messages are issued with syslogd priority code **info**.

8 (Event)

Enables tracing of major events. The messages are issued with syslogd priority code **debug**.

16 (Flow)

Enables tracing of system SSL calls. The messages are issued with syslogd priority code **debug**.

32 (Data)

Enables tracing of encrypted negotiation and headers. This value traces the negotiation of secure sessions. The messages are issued with syslogd priority code **debug**.

64

Reserved.

128

Reserved.

255

Enables all tracing.

If you specify Security Basic, this parameter is ignored.

Keyring

A string 1 - 1 023 in length that specifies the ring name of the SAF key ring. A SAF key ring is specified as *userid/keyring*. The *userid* must be the z/OS user ID that owns the keyring. If *userid* is not specified, the user ID under which the Policy Agent is executing will be used. This key ring typically contains the certificates of the trusted (by the client) Certificate Authorities.

Restriction: If Security is configured with Secure, then this parameter is required.

If you specify Security Basic, this parameter is ignored.

SetSubnetPrioTosMask statement

Use the SetSubnetPrioTosMask statement to define a mapping of IPv4 Type of Service (ToS) byte or IPv6 Traffic Class to outbound interface device and virtual LAN (VLAN) user priority values. It maps priorities for interfaces that use OSA. If this statement is not specified, TCP/IP uses the system default ToS or Traffic Class mask and priority levels for all interfaces currently defined for IPv4 (RFC 791).

The current IPv4 ToS byte format defines the first 3 bits to be the precedence bits (for example, priority). Therefore, the default for the subnet ToS mask, if this statement is not specified, is 11 100 000. The same default mask also applies to IPv6 Traffic Class.

Restrictions:

- Only OSA can support priorities.
- A maximum of 16 SetSubnetPrioTosMask statements can be specified for each TCP/IP stack.

This statement sets up ToS or Traffic Class to priority mapping for those devices. OSA supports four priority levels, 1 - 4, with 4 being the lowest priority. Following is the default mapping of these four priorities to the various ToS byte or Traffic Class values:

ToS	Priority
00000000	4
00100000	4
01000000	3
01100000	2
10000000	1
10100000	1
11000000	1
11100000	1

The ToS byte or Traffic Class is also used by other network devices (for example, routers and switches) to determine the priority of a packet.

Guideline: If Enterprise Extender has set ToS bytes, this overrides those settings.

Tip: An outbound packet with a ToS or Traffic Class value that consists of zeros allows for prioritizing outbound OSA data using the WorkLoad Manager service class importance level. See the information about Prioritizing outbound OSA data using the WorkLoad Manager service class in [z/OS Communications Server: IP Configuration Guide](#) for more information about using WorkLoad Manager service class importance level values with OSA interfaces.

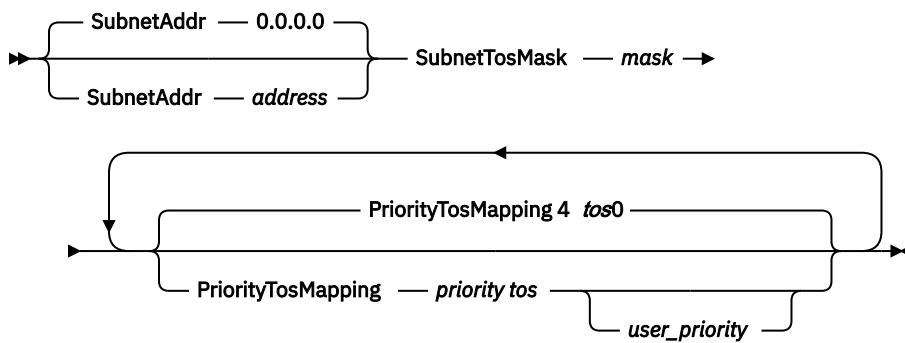

Syntax

➤➤ SetSubnetPrioTosMask — Place Braces and Parameters on Separate Lines ➤➤

Place Braces and Parameters on Separate Lines

SetSubnetPrioTosMask Parameters

Parameters

SubnetAddr

The local subnet interface address. This can be an IPv4 address or an interface name. A value of 0 indicates that the mask is the same for all interfaces. The default is all interfaces. All interfaces are the same as coding a value of 0, or not specifying this parameter.

Requirement: If an interface name is specified, it must match a name specified on one of the following statements in the TCP/IP profile:

- LINK statement for an IPv4 interface
- INTERFACE statement for an IPv4 or IPv6 interface

SubnetTosMask

SubnetTosMask contains eight bits, left-aligned, for the ToS or Traffic Class mask. For example, 101 would be 10 100 000. There is no default.

Requirement: This is a required parameter.

PriorityTosMapping

Three values to indicate each priority level to ToS or Traffic Class value mapping. The first value of each mapping is an integer to indicate the device priority level, the second value is eight bits, left-aligned, to indicate the ToS or Traffic Class value, and the third value is an optional integer to indicate the user priority (0 - 7, where 0 is the lowest priority). User priority is also known as virtual LAN (VLAN) priority.

Restrictions:

- If this parameter is not specified for a ToS or Traffic Class value, that value maps to a device priority value of 4, and a user priority value of 0.
- A maximum of 32 PriorityTosMapping parameters can be specified.

Result: Coding the virtual LAN (VLAN) user priority causes a frame to be sent out based on the IEEE 802.1Q specification, which establishes a standard method for tagging Ethernet frames with VLAN priority and membership information. Specifically, a VLAN priority-tagged frame is used to convey packet priority to the switches; it has a value of NULL for VLANID. A full VLAN-tagged frame contains both the priority and non-null VLANID. If you have switches in your network that do not support the IEEE 802.1Q standard or that are not properly configured for these types of frames, the frames might be dropped by the switch.

Examples

```

SetSubnetPrioTosMask
{
  SubnetAddr NSQDI03
  SubnetTosMask 11100000
  PriorityTosMapping 1 11100000 7
  PriorityTosMapping 1 11000000 7
  PriorityTosMapping 2 10100000 6
  PriorityTosMapping 2 10000000 5
  PriorityTosMapping 2 01100000 5
}
  
```

```

PriorityTosMapping 3 01000000 3
PriorityTosMapping 4 00100000 2
PriorityTosMapping 4 00000000 0
}

```

```

SetSubnetPrioTosMask
{
SubnetTosMask 11100000
PriorityTosMapping 1 11100000
PriorityTosMapping 1 11000000
PriorityTosMapping 1 10100000
PriorityTosMapping 1 10000000
PriorityTosMapping 2 01100000
PriorityTosMapping 2 01000000
PriorityTosMapping 3 00100000
PriorityTosMapping 4 00000000
}

```

TcpImage and PEPInstance statement

Use the TcpImage and PEPInstance statements to specify a TCP/IP image and its associated image configuration file to be installed to that image. These statements are synonyms and you can use either of them. If no TcpImage statement is specified, any policy definitions are installed to the default TCP/IP image (resolver supplied TCPIPuserid statement or TCPIPjobname statement). The parameters FLUSH or NOFLUSH can be used to force deletion of some policy types from the stack at startup and certain other events. The parameters PURGE or NOPURGE can be used to delete some policy types from the stack during normal shutdown (for example, KILL or STOP).

A single stack environment is defined in BPXPRMxx parmlib member by setting 'FILESYSTYPE TYPE(INET)'. For more information, see [z/OS UNIX System Services Planning](#).

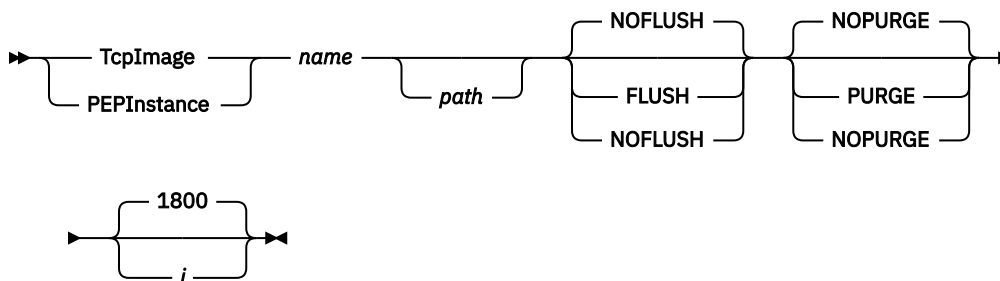

The Policy Agent uses the TcpImage statement within a single stack environment in the following ways:

- If one or more TcpImage statements are specified, Policy Agent always uses the default TCP/IP image (resolver supplied TCPIPuserid statement or TCPIPjobname statement). All associated policy control statements are installed to the active TCP/IP stack.
- If no TcpImage statement is specified, any control statements are installed to the active TCP/IP stack.
- If Policy Agent cannot determine the name of the TCP/IP image (resolver supplied TCPIPuserid statement or TCPIPjobname statement), INET is the default name used. Any control statements are installed to the active TCP/IP stack.

Result: If the default TCP/IP image (resolver supplied TCPIPuserid statement or TCPIPjobname statement) is not the same as the active TCP/IP stack, the following situations occur:

- The default TCP/IP stack name is used in messages and displays. Policy Agent creates an internal TcpImage statement with default values to represent the specified TCP/IP image.
- The interface used by the stack to inform the Policy Agent about stack restarts does not function.

Syntax

Parameters

name

The jobname of the TCP/IP image.

Requirement: The name must be one to eight characters in length.

path

The path of the image configuration file to be installed. If an image configuration file is not specified, the following policy definitions (if any) in this policy configuration file are installed.

You can specify an MVS data set name or a z/OS UNIX file name. MVS data set names must be enclosed in single quotation marks (' ') and preceded by a double slash (/). Following are examples of both types of names:

```
TcpImage  TCPIP1  //'USER1.PAGENT.CONF(TCPIP1)'  FLUSH  PURGE
TcpImage  TCPIP1  /u/user1/pagent.tcpip1  FLUSH  PURGE
```

FLUSH

Specifies that all policies installed in the Policy Agent and the TCP/IP stack are deleted when:

- A new TcpImage statement is processed for the first time, including Policy Agent starting.
- A MODIFY PAGENT,REFRESH command is entered.

NOFLUSH

Specifies that all policies installed in the Policy Agent and the TCP/IP stack are to remain during initial startup and at each refresh interval. In addition, policies that are deleted from a configuration are not deleted from the Policy Agent or the TCP/IP stack. This is the default.

PURGE

Specifies that all policies installed in the TCP/IP stack are deleted during normal termination, and also when a TcpImage or PEPIInstance statement is deleted.

NOPURGE

Specifies that all policies installed in the TCP/IP stack remain during normal termination and when a TcpImage or PEPIInstance statement is deleted. This is the default.

For details, see the [FLUSH and PURGE information in z/OS Communications Server: IP Configuration Guide](#).

i

An integer that specifies the time interval (in seconds) for checking the creation or modification time of the configuration file or files, and for refreshing policies from the LDAP server. The maximum value is 2 147 483 647. In the following cases, the update interval is changed:

- If a value is not specified, the default is 1 800 seconds (30 minutes).
- If a value of 0 is specified, the default value of 1 800 (30 minutes) is used.
- Any value in the range 1 - 59 is rounded up to 60 seconds (1 minute).

The Policy Agent always uses this time interval to check for changes, but also monitors the configuration file or files in real time if the -i startup option is specified. The smallest refresh interval specified on the set of TcpImage statements is used as the refresh interval for the main configuration file.

For example, if -i is set to 300, the corresponding configuration files and LDAP server are checked for changes every five minutes. If the configuration file or files have changed within the last 5 minutes, they are read again. The LDAP server (if configured) is also queried again for policies. Any new, changed, or deleted policies are installed to or removed from the stack as appropriate.

Restriction: Dynamic monitoring for file updates using the -i startup option is supported only for z/OS UNIX files; MVS data sets are not monitored for changes.

Rules: To dynamically add a TCP/IP stack to the Policy Agent configuration, take one of the following actions in addition to adding the `TcpImage` statement to the configuration file. This automatically installs active policies.

- If the Policy Agent was started with the `-i` startup option, no further action is necessary. Active policies are automatically installed to the stack when it becomes active.
- If the Policy Agent was not started with the `-i` startup option, take one of the following actions:
 - Issue the `MODIFY REFRESH` or `MODIFY UPDATE` command after the stack becomes active. If the `MODIFY REFRESH` or `MODIFY UPDATE` command is issued before the stack becomes active, policies are not automatically installed.
 - Wait on the next update interval to check for configuration changes. If the stack is not active, policies are not automatically installed.

Examples

The following example installs the image configuration file `/tmp/TCPCS.policy` to the `TCPCS` TCP/IP image, after flushing existing policy control data:

```
TcpImage TCPCS /tmp/TCPCS.policy FLUSH
```

TTLSSConfig statement

Use the `TTLSSConfig` statement to specify the path of a local AT-TLS policy file that contains stack-specific AT-TLS policy statements. The `TTLSSConfig` statement is required to define AT-TLS policy for a given stack. To define a common set of policies for multiple stacks, the `TTLSSConfig` statement can be specified without a path name.

Requirement: The `TTLSSConfig` statement is required to define AT-TLS policy for a given stack.

Results: For the associated TCP/IP image on the policy client, if the `PolicyServer` statement specifies remote AT-TLS policies, then one the following situations occurs:

- If no local AT-TLS policies are installed, then the `TTLSSConfig` statement is ignored.
- If local AT-TLS policies are already installed, then the result is the same as if the `TTLSSConfig` statement had been deleted.

Rule: For AT-TLS policies, if errors are detected during parsing, no new policies are installed.

The `FLUSH/NOFLUSH` and `PURGE/NOPURGE` parameters can be used to specify whether or not AT-TLS policies are deleted at startup (and when a `MODIFY REFRESH` command is entered) and shutdown, respectively.

The refresh interval for the `TTLSSConfig` file is inherited from the image configuration file containing the corresponding `TTLSSConfig` statement.

Specify the `TTLSSConfig` statement without a path name in each image configuration file to define a common set of policies for multiple stacks.

The `TTLSSConfig` statement can appear only in an image configuration file. If a `TTLSSConfig` statement appears multiple times in an image configuration file, the last occurrence of the statement is used. If the `TTLSSConfig` statement appears in the main configuration file, it is ignored (unless the main and image configuration files are the same file).

Syntax

Parameters

path

The path of the stack-specific AT-TLS policy file to be installed. If no path name is specified, then the common AT-TLS policy file specified on the CommonTTLSSConfig statement is used.

You can specify an MVS data set name or a z/OS UNIX file name. MVS data set names must be enclosed in single quotation marks (' ') and preceded by a double slash (/). Following are examples of both types of names:

```
TTLSSConfig // 'USER1.PAGENT.CONF(TTLS) '  
TTLSSConfig /u/user1/pagent.ttls
```

Restriction: Dynamic monitoring for file updates using the -i startup option is supported only for z/OS UNIX files; MVS data sets are not monitored for change.

FLUSH

FLUSH specifies that all policies installed in the Policy Agent and the TCP/IP stack are deleted. Policies are flushed at the following times:

- When a new TcpImage statement is processed for the first time, including Policy Agent starting
- When a MODIFY REFRESH command is entered

NOFLUSH

NOFLUSH specifies that all policies installed in the Policy Agent and the TCP/IP stack are to remain during initial startup and at each refresh interval. In addition, policies that are deleted from a configuration are not deleted from the Policy Agent or the TCP/IP stack.

PURGE

Specifies that all policies installed in the TCP/IP stack are deleted during normal termination, and also when a TcpImage or PEPInstance statement is deleted.

NOPURGE

Specifies that all policies installed in the TCP/IP stack remain during normal termination and when a TcpImage or PEPInstance statement is deleted.

For details, see the [FLUSH and PURGE information](#) in [z/OS Communications Server: IP Configuration Guide](#).

Result: If the TTLSSConfig statement is deleted and FLUSH configured, then all AT-TLS policies are deleted from the corresponding stack.

ZERTConfig statement

Use the ZERTConfig statement to specify the path of a local ZERT policy file that contains stack-specific ZERT policy statements.

Requirement: The ZERTConfig statement is required to define ZERT policy for a given stack.

Results: For the associated TCP/IP image on the policy client, if the PolicyServer statement specifies remote ZERT policies, then the following occurs:

- If no local ZERT policies are installed, then the ZERTConfig statement is ignored.
- If local ZERT policies are already installed, then the result is the same as if the ZERTConfig statement had been deleted.

Rule: For ZERT policies, when errors are detected during parsing, no new policies are installed.

The refresh interval for the ZERTConfig file is inherited from the image configuration file containing the corresponding ZERTConfig statement.

Restriction: The ZERTConfig statement can appear only in an image configuration file. If a ZERTConfig statement appears multiple times in an image configuration file, the last occurrence of the statement is

used. If the ZERTConfig statement appears in the main configuration file, it is ignored (unless the main and image configuration files are the same file).

Syntax

➡ ZERTConfig — path ➡

Parameters

path

Specifies the path of the stack-specific ZERT policy file to be installed.

You can specify an MVS data set name or a z/OS UNIX file name. MVS data set names must be enclosed in single quotation marks (' ') and preceded by a double slash (/). Following are examples of both types of names:

```
ZERTConfig  //'USER1.PAGENT.CONF(ZERT) '  
ZERTConfig  /u/user1/pagent.ZERT
```

Restriction: Dynamic monitoring for file updates using the -i startup option support is not available for ZERT policy files.

Result:

- After a TCP/IP stack has been recycled, all active policies are reinstalled.
- If the ZERTConfig statement is deleted, all ZERT policies are deleted from the corresponding stack.

AT-TLS policy statements

This topic contains information about the following AT-TLS policy statements:

- [“TTLSCipherParms statement” on page 897](#)
- [“TTLSConnectionAction statement” on page 902](#)
- [“TTLSConnectionAdvancedParms statement” on page 905](#)
- [“TTLSEnvironmentAction statement” on page 914](#)
- [“TTLSEnvironmentAdvancedParms statement” on page 917](#)
- [“TTLSGroupAction statement” on page 929](#)
- [“TTLSGroupAdvancedParms statement” on page 932](#)
- [“TTLSGskAdvancedParms statement” on page 933](#)
- [“TTLSGskHttpCdpParms statement” on page 940](#)
- [“TTLSGskLdapParms statement” on page 941](#)
- [“TTLSGskOcspParms statement” on page 944](#)
- [“TTLSSignatureParms statement” on page 951](#)
- [“TTLSSignatureParms statement” on page 952](#)
- [“TTLSSignatureParms statement” on page 956](#)

Consider the following guidelines when using the AT-TLS policy statements.

Guidelines:

- While configuring AT-TLS policy, see [z/OS Cryptographic Services System SSL Programming](#) for a detailed description of each of the System SSL attributes that are being configured using the AT-TLS policy statements (System SSL attributes are those that begin with GSK). See the information describing the `gsk_attribute_set_buffer` API, the `gsk_attribute_set_enum` API, and the `gsk_attribute_set_numeric_value` API descriptions of how each attribute is used by System SSL, as well as the meaning of available attribute settings and default attribute settings.

- AT-TLS requires a valid z/OS UNIX key database, SAF key ring, or z/OS PKCS #11 token. For more information about [Application Transparent Transport Layer Security data protection](#), see [z/OS Communications Server: IP Configuration Guide](#).
- AT-TLS can be configured to write trace data to syslogd. AT-TLS writes messages to syslogd using the daemon or auth facility. See [Chapter 15, “Syslog daemon,”](#) on page 795 for more information about configuring syslogd.
- If System SSL needs to access ICSF, ICSF must be started before you start the Policy Agent. For information about using hardware Cryptographic Features with System SSL, see [z/OS Cryptographic Services System SSL Programming](#).

Note the following results when using the AT-TLS policy statements.

Results: When using AT-TLS policy statements, consider the following results:

- When an IpAddrGroup statement contains non-continuous ranges of IP addresses, or a PortGroup statement contains non-continuous ranges of port numbers, Policy Agent cannot merge these conditions into a single condition. The group's ranges are displayed by pasearch, as configured, with the summary condition for each of these respective attributes equal to the lowest **from** value in the group to the highest **to** value in the group. If an IP address of value 0.0.0.0 exists in an IpAddrGroup statement, the summary condition for this attribute is set to **All**. If a Port of value 0 exists in a PortGroup statement, the summary condition for this attribute is set to the range **0-0**. When an IpAddrGroup statement contains a mixture of IPv4 and IPv6 addresses, a summary condition cannot be created. The group's ranges are displayed by pasearch, as configured, with a summary condition for this attribute of **All**.
- For optional parameters that have default values and are not specified, pasearch displays the default value when the parameter is not configured.
- For optional parameters that do not have default values and are not specified, pasearch does not display the parameter.
- If an optional parameter is not specified for a GSK statement, System SSL uses its default value.
- A rule can reference a TTLSConnectionAction, a TTLSEnvironmentAction, and a TTLSGroupAction. For parameters that can be specified in multiple action types, the value used by a connection is determined by the following hierarchical rule set.
 1. If the parameter is specified in the TTLSConnectionAction statement referenced by the matching rule, this value is used.
 2. Else, if the parameter is specified in the TTLSEnvironmentAction statement referenced by the matching rule, this value is used.
 3. Else, if the parameter is specified in the TTLSGroupAction statement referenced by the matching rule, this value is used.
 4. Else, if a default value is defined, that is the value used.
 5. Otherwise, no value is used by AT-TLS and no parameter is explicitly passed to System SSL.
- Each AT-TLS action has a user instance variable (GroupUserInstance, EnvironmentUserInstance, and ConnectionUserInstance). These parameters can be used to cause Policy Agent to refresh a specific action, when using the `-i` startup option or when a refresh interval is coded.

Tip: For an example of AT-TLS policy definitions see `/usr/lpp/tcpip/samples/pagent_TTLS.conf`

TTLSCipherParms statement

Use the TTLSCipherParms statement to define the cipher specifications for an AT-TLS environment or an AT-TLS connection. A TTLSCipherParms statement can be specified inline in a TTLSEnvironmentAction or TTLSConnectionAction statement or referenced by a TTLSEnvironmentAction or TTLSConnectionAction statement.

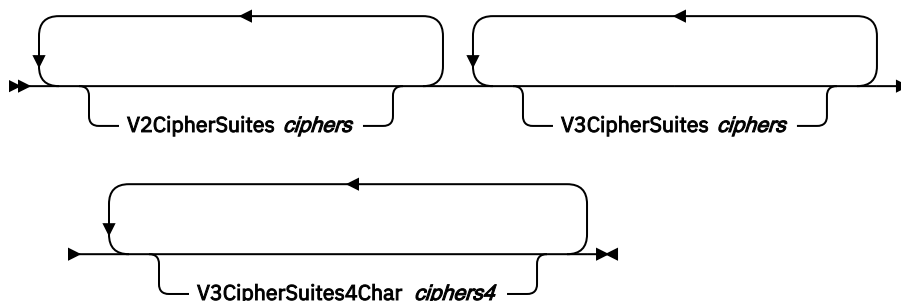

Syntax

Put Braces and Parameters on Separate Lines

TTLSCipherParms Parameters

Parameters

name

A string 1 - 32 characters in length specifying the name of this TTLSCipherParms statement.

Rule: If this TTLSCipherParms statement is not specified inline within another statement, a *name* value must be provided. If a name is not specified for an inline TTLSCipherParms statement, a nonpersistent system name is created.

V2CipherSuites

Specifies the SSL version 2 cipher suites in order of preference. If a V2CipherSuites parameter is specified more than once, the values are concatenated to create a single list of cipher suites. For System SSL, the GSK_V2_CIPHER_SPECS value is set to the concatenated value.

The *ciphers* value is a string of one or more 1-character SSL version 2 ciphers or a single cipher constant. The cipher string cannot have blanks between each SSL version 2 cipher. If duplicate ciphers are specified, the first instance is used and all other instances are ignored. The maximum number of SSL version 2 ciphers is 10. For System SSL, see *gsk_environment_open()* in [z/OS Cryptographic Services System SSL Programming](#) for a list of valid cipher suites. [Table 73](#) on page 898 lists the supported cipher constants.

Table 73. V2CipherSuites

Cipher constant	Hexadecimal character
TLS_RC4_128_WITH_MD5	1
TLS_RC4_128_EXPORT40_WITH_MD5	2
TLS_RC2_CBC_128_CBC_WITH_MD5	3
TLS_RC2_CBC_128_CBC_EXPORT40_WITH_MD5	4
TLS_DES_64_CBC_WITH_MD5	6
TLS_DES_192_EDE3_CBC_WITH_MD5	7

V3CipherSuites

Specifies the SSL Version 3, TLS Version 1.0, TLS Version 1.1, TLS Version 1.2, or TLS Version 1.3 cipher suites in order of preference. If a V3CipherSuites or V3CipherSuites4Char parameter is specified more than once, the values are concatenated to create a single list of cipher suites. For System SSL, the GSK_V3_CIPHER_SPECS_EXPANDED value is set to the concatenated value.

The *ciphers* value is a string of one or more 2-hexadecimal character SSL Version 3, TLS version 1.0, TLS Version 1.1, or TLS Version 1.2 ciphers or a single cipher constant. The cipher string cannot have blanks between each SSL Version 3, TLS version 1.0, TLS Version 1.1, or TLS Version 1.2 cipher. If the string notation is used, you cannot specify any cipher values that require four character representation. Use the V3CipherSuites4Char parameter to specify four character cipher string values. If duplicate ciphers are specified, the first instance is used and all other instances ignored. The maximum number of ciphers that can be specified is 255. For System SSL, see *Appendix C. Cipher suite definitions* in *z/OS Cryptographic Services System SSL Programming* for a list of valid cipher suites. Table 74 on page 899 lists the supported cipher constants.

V3CipherSuites4Char

Specifies the SSL Version 3, TLS Version 1.0, TLS Version 1.1, TLS Version 1.2 or TLS Version 1.3 cipher suites in order of preference. If a V3CipherSuites or V3CipherSuites4Char parameter is specified more than once, the values are concatenated to create a single list of cipher suites. For System SSL, the GSK_V3_CIPHER_SPECS_EXPANDED value is set to the concatenated value.

The *ciphers* value is a string of one or more 4-hexadecimal character SSL Version 3, TLS version 1.0, TLS Version 1.1, TLS Version 1.2 or TLS Version 1.3 ciphers. The cipher string cannot have blanks between each SSL Version 3, TLS version 1.0, TLS Version 1.1, TLS Version 1.2 or TLS Version 1.3 cipher. Use the V3CipherSuites parameter to specify a cipher constant or 2-character cipher string values. If duplicate ciphers are specified, the first instance is used and all other instances ignored. The maximum number of ciphers that can be specified is 255.

For System SSL, see *Appendix C. Cipher suite definitions* in *z/OS Cryptographic Services System SSL Programming* for a list of valid cipher suites by supported protocol. Table 74 on page 899 lists the supported cipher constants.

Table 74. V3CipherSuites/V3CipherSuites4Char		
Cipher constant	Hexadecimal character	Expanded character
TLS_NULL_WITH_NULL_NULL	00	0000
TLS_RSA_WITH_NULL_MD5	01	0001
TLS_RSA_WITH_NULL_SHA	02	0002
TLS_RSA_EXPORT_WITH_RC4_40_MD5	03	0003
TLS_RSA_WITH_RC4_128_MD5	04	0004
TLS_RSA_WITH_RC4_128_SHA	05	0005
TLS_RSA_EXPORT_WITH_RC2_CBC_40_MD5	06	0006
TLS_RSA_WITH_DES_CBC_SHA	09	0009
TLS_RSA_WITH_3DES_EDE_CBC_SHA	0A	000A
TLS_DH_DSS_WITH_DES_CBC_SHA	0C	000C
TLS_DH_DSS_WITH_3DES_EDE_CBC_SHA	0D	000D
TLS_DH_RSA_WITH_DES_CBC_SHA	0F	000F
TLS_DH_RSA_WITH_3DES_EDE_CBC_SHA	10	0010
TLS_DHE_DSS_WITH_DES_CBC_SHA	12	0012

Table 74. V3CipherSuites/V3CipherSuites4Char (continued)

Cipher constant	Hexadecimal character	Expanded character
TLS_DHE_DSS_WITH_3DES_EDE_CBC_SHA	13	0013
TLS_DHE_RSA_WITH_DES_CBC_SHA	15	0015

Requirement: If you plan to control access to the ICSF cryptographic support, TCP/IP and other applications must be permitted to access the ICSF/MVS cryptographic services (CSFSERV).

Guideline: If you do not have any reason to restrict access to the ICSF cryptographic support, you should not activate the CSFSERV resource class, define any of the profiles listed below, or permit any applications or users to these profiles. If you do need to set up controls in the CSFSERV resource class, enable the following resources.

Requirement: Elliptic Curve ciphers, defined as TLS_ECDH, TLS_ECDHE or TLS_ECDSA, require ICSF to be active. Ciphers TLS_AES_128_GCM_SHA256, TLS_AES_256_GCM_SHA384 and TLS_CHACHA20_POLY1305_SHA256 also require ICSF to be active.

The user ID running the AT-TLS application must have READ access to the following resources in the CSFSERV class:

- CSF1DVK
- CSF1GKP
- CSF1GAV
- CSF1PKS
- CSF1PKV
- CSF1TRC
- CSF1TRD

See [Elliptic Curve Cryptography Support](#) [elliptic curve cryptography support in z/OS Cryptographic Services System SSL Programming](#) for additional information.

Requirement: AES-GCM ciphers require ICSF to be active.

The user ID running the AT-TLS application must have READ access to the following resources in the CSFSERV class:

- CSF1TRC
- CSF1SKD
- CSF1SKE
- CSF1TRD

TTLSTLSConnectionAction statement

Use the TTLSTLSConnectionAction statement to specify attributes for a subset of connections that need attributes different from those specified on the TTLSTLSEnvironmentAction or TTLSTLSGroupAction statement that is referenced by the same TTLSTLSRule statement.

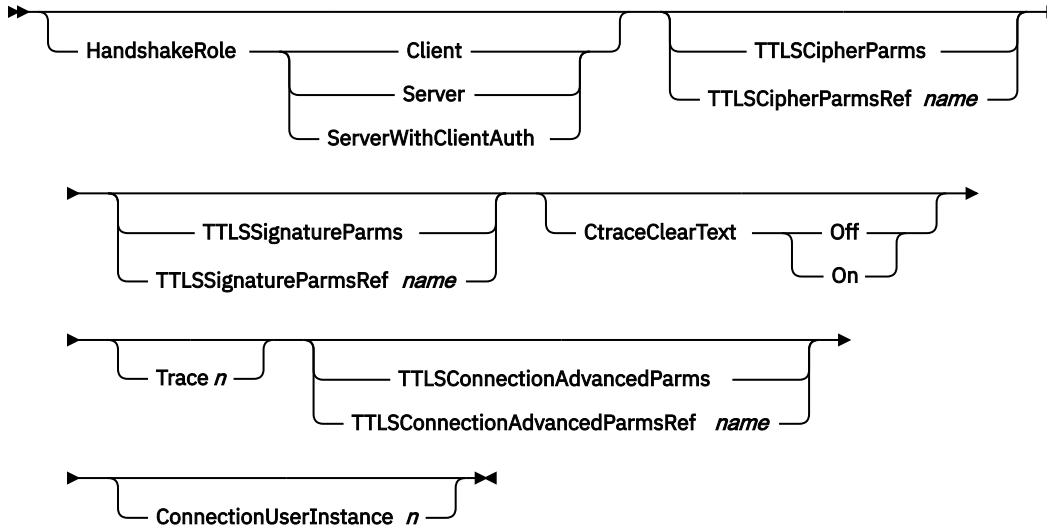

Syntax

➤ TLSConnectionAction — *name* — Put Braces and Parameters on Separate Lines ➤

Put Braces and Parameters on Separate Lines

TLSConnectionAction Parameters

Parameters

name

A string 1 - 32 characters in length specifying the name of this TLSConnectionAction statement.

HandshakeRole

Specifies the SSL handshake role to be taken. For System SSL, the GSK_SESSION_TYPE value is set to the same value as the HandshakeRole. If this value is specified on the TLSConnectionAction statement, it is used instead of the value from the TTLSEnvironmentAction statement referenced by the same TTLSRule statement. Valid values are:

Client

Perform the SSL handshake as a client.

Server

Perform the SSL handshake as a server.

ServerWithClientAuth

Perform the SSL handshake as a server requiring client authentication.

TTLSCipherParams

An inline specification of a TTLS cipherParams statement. If this value is specified on the TLSConnectionAction statement, it is used instead of the value from the TTLSEnvironmentAction statement referenced by the same TTLSRule statement.

TTLSCipherParamsRef

The name of a globally defined TTLS cipherParams statement. If this value is specified on the TLSConnectionAction statement, it is used instead of the value from the TTLSEnvironmentAction statement referenced by the same TTLSRule statement.

TTLSSignatureParms

An inline specification of a TTLSSignatureParms statement. If this value is specified on the TTLSCONNECTIONACTION statement, it is used instead of the value from the TTLSEnvironmentAction statement that is referenced by the same TTLSRule statement.

TTLSSignatureParmsRef

The name of a globally defined TTLSSignatureParms statement. If this value is specified on the TTLSCONNECTIONACTION statement, it is used instead of the value from the TTLSEnvironmentAction statement that is referenced by the same TTLSRule statement.

CtraceClearText

Specifies whether application data traced using Ctrace or data trace are shown as unencrypted data. This parameter is applied only to connections that have active AT-TLS security on the connection. If this value is specified on the TTLSCONNECTIONACTION statement, it is used instead of the value from the TTLSEnvironmentAction or TTLSGROUPACTION statement referenced by the same TTLSRule statement. Valid values are:

Off

Application data is not traced as clear text.

On

Application data is traced as clear text.

Trace

Specifies the level of Application Transparent Transport Layer Security (AT-TLS) tracing. The valid values for *n* are in the range 0 - 255. There is no default value. The sum of the numbers associated with each level of tracing selected is the value that should be specified as *n*. If *n* is an odd number, errors are written to joblog, and all other configured traces are sent to syslogd. If this value is specified on the TTLSCONNECTIONACTION statement, it is used instead of the value from the TTLSEnvironmentAction or TTLSGROUPACTION statement referenced by the same TTLSRule statement.

Tip: The Trace parameter can be specified for the TTLSGROUPACTION, the TTLSEnvironmentAction, and the TTLSCONNECTIONACTION. To determine the value in effect for a TTLSRule statement, examine each referenced action. The most specific action with the Trace parameter specified determines the value used. If the value is not specified for any of the referenced actions, the default value of 2 for the TTLSGROUPACTION is in effect.

0

No tracing is enabled.

1 (Error)

Errors are traced to the TCP/IP joblog.

2 (Error)

Errors are traced to syslogd. The messages are issued with syslogd priority code **err**.

4 (Info)

Tracing of when a connection is mapped to an AT-TLS rule and when a secure connection is successfully initiated is enabled. The messages are issued with syslogd priority code **info**.

8 (Event)

Tracing of major events is enabled. The messages are issued with syslogd priority code **debug**.

16 (Flow)

Tracing of system SSL calls is enabled. The messages are issued with syslogd priority code **debug**.

32 (Data)

Tracing of encrypted negotiation and headers is enabled. This traces the negotiation of secure sessions. The messages are issued with syslogd priority code **debug**.

64

Reserved.

128

Reserved.

255

All tracing is enabled.

TTLSTConnectionAdvancedParms

An inline specification of a TTLSTConnectionAdvancedParms statement.

TTLSTConnectionAdvancedParmsRef

The name of a globally defined TTLSTConnectionAdvancedParms statement.

ConnectionUserInstance

Defines a configurable instance identifier for this TTLSTConnectionAction statement. The *n* value can be in the range 0 - 65535. This parameter can be used to signal a change to the Policy Agent without modifying any of the other AT-TLS configuration statements. This parameter can also be used as a field to be updated when a change is made to this TTLSTConnectionAction statement. This enables the user to differentiate TTLSTConnectionAction statements, based on the instance identifier.

TTLSTConnectionAdvancedParms statement

Use the TTLSTConnectionAdvancedParms statement to specify attributes for a subset of connections that need attributes different from those specified on the TTLSTEnvironmentAdvancedParms statement that is referenced by the same TTLSTRule statement.

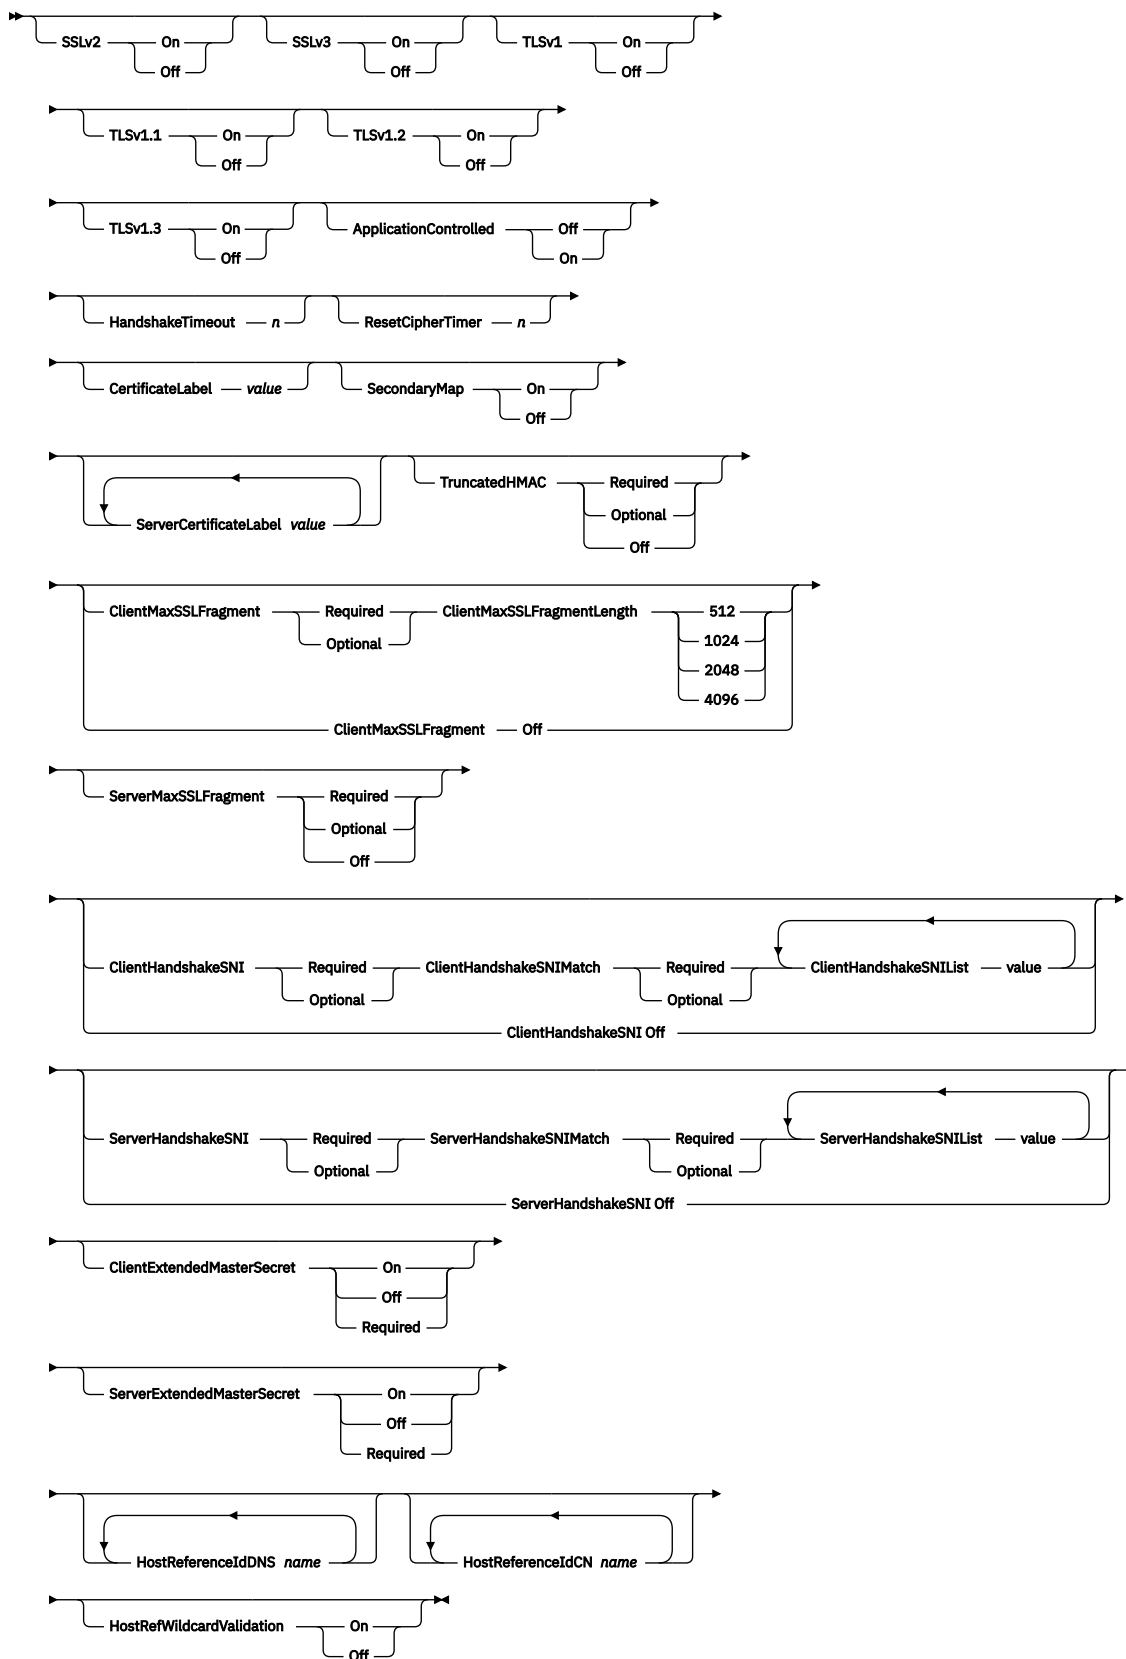

Syntax

Put Braces and Parameters on Separate Lines

TTLSTConnectionAdvancedParms Parameters

Parameters

name

A string 1 - 32 characters in length specifying the name of this TTLSConnectionAdvancedParms statement.

Rule: If this TTLSConnectionAdvancedParms statement is not specified inline within another statement, a *name* value must be provided. If a name value is not specified for an inline TTLSConnectionAdvancedParms statement, a nonpersistent system name is created.

ApplicationControlled

Specifies whether the application can control AT-TLS security for a connection. Valid values are:

Off

An application cannot control AT-TLS security. The connection automatically negotiates AT-TLS security.

On

An application can control AT-TLS security. AT-TLS security is used only when requested by the application, using the SIOCTLSSLCTL ioctl.

CertificateLabel

Specifies the label of the certificate to be used for authentication. Valid values are in the range 1 - 127 characters in length. For System SSL, the GSK_KEYRING_LABEL value is set to this value.

Rule: Comment indicators and embedded blanks are treated as part of the value for this attribute. For example:

```
CertificateLabel Root#CA Certificate
value used:    Root#CA Certificate
```

Restriction: When the value contains embedded blanks, you must specify the entire value within the first 1 536 characters of the configuration file line.

ClientExtendedMasterSecret

Specifies whether the TLS client supports the extended master secret (EMS) computation for TLSv1.0, TLSv1.1 and TLSv1.2 negotiations. This support is negotiated by the client and server. When the TLS client supports the EMS computation, it will include the EMS extension on the Client Hello message if TLSv1.0, TLSv1.1, or TLSv1.2 is enabled. If the server also supports the EMS computation, it will include the EMS extension on the Server Hello message for a TLSv1.0, TLSv1.1, or TLSv1.2 negotiation. The EMS extension is defined by RFC 7627.

Possible values are:

On

Specifies that the TLS client (when enabled for TLSv1.0, TLSv1.1, or TLSv1.2) will send an EMS extension to the server. If the server responds with an EMS extension for a TLSv1.0, TLSv1.1, or TLSv1.2 handshake, the EMS computation will be used. If the server does not send an EMS extension the handshake can still succeed but the standard master secret derivation is used.

Required

Specifies that the TLS client (when enabled for TLSv1.0, TLSv1.1, or TLSv1.2) will send an EMS extension to the server and requires that the server respond with an EMS extension for a TLSv1.0, TLSv1.1, or TLSv1.2 handshake. If the server does not indicate support by sending the EMS extension, the handshake fails.

Off

Specifies that the TLS client (when enabled for TLSv1.0, TLSv1.1, or TLSv1.2) will not send the EMS extension to the server during the handshake.

ClientHandshakeSNI

For TLSv1.0 protocol or later, this keyword specifies whether a client can specify a list of server names. The server chooses a certificate based on that server name list for this connection. For System SSL, the extension ID is set to GSK_TLS_SET_SNI_CLIENT_SNAMES and a flag is set in the gsk_tls_extension structure if it is required. Valid values are:

Required

Specifies that server name indication support must be accepted by the server. Connections fail if the server does not support server name indication.

Tip: When you specify ClientHandshakeSNI as required, specify SSLv3 as Off.

Optional

Specifies that server name indication negotiation is supported, but allows connections with servers that do not support server name indication negotiation.

Off

Specifies that server name indication is not supported. The function is not enabled. Connections fail if the server requires support for server name indication. This is the default.

ClientHandshakeSNIMatch

Code this parameter if ClientHandshakeSNI is set to Required or Optional. For system SSL, a flag is set in the gsk_sni_client_snames structure if a match is required. Possible values are:

Required

Specifies that a server name in the list of server names provided by the TLS client must match a server name in the list of server names and certificate labels on the TLS server. The connection ends if no match was found for the server name at the server.

Optional

Specifies that connections can continue if no match is found for the server name.

ClientHandshakeSNIList

For SSL clients using TLSv1.0 protocol or later, this keyword specifies a server name. You can code multiple ClientHandshakeSNIList statements. The list of server names is passed to the server in the SSL handshake. For System SSL, the server names are anchored in the gsk_sni_client_snames structure. A server name can be 1 - 255 characters in length. This parameter is required when ClientHandshakeSNI is set to Required or Optional.

Restriction: The total length of all the server names specified must be less than 32K.

ClientMaxSSLFragment

For TLSv1.0 protocol or later, this keyword specifies whether the maximum SSL fragment function is supported when AT-TLS is the TLS client on the connection. For System SSL, the extension ID is set to GSK_TLS_SET_CLIENT_MFL and a flag is set in the gsk_tls_extension structure if it is required. Possible values are:

Required

Specifies that maximum SSL fragment function support must be accepted by the server. Connections fail if the server does not support the maximum SSL fragment function.

Tip: When you specify ClientMaxSSLFragment as Required, specify SSLv3 as Off.

Optional

Specifies support for maximum SSL fragment function negotiation, but allows connections with servers that do not support maximum SSL fragment function.

Off

Specifies that maximum SSL fragment function negotiation is not supported. The function is not enabled. Connections fail if the server requires support for maximum SSL fragment function.

ClientMaxSSLFragmentLength

Specifies the maximum SSL fragment function, in bytes, to request on the connection when AT-TLS is the TLS client using TLSv1.0 protocol or later. The valid values are 512, 1024, 2048, and 4096. For System SSL, the maximum fragment function is set to GSK_TLS_MFL_512, GSK_TLS_MFL_1024, GSK_TLS_MFL_2048, or GSK_TLS_MFL_4096. This parameter is required when ClientMaxSSLFragment is set to Required or Optional.

HandshakeTimeout

Specifies the number of seconds to wait for the initial handshake to complete. Valid values of *n* are in the range 0 - 600.

For connections with the HandshakeRole parameter set to Client, the timer is initially set to 5 times the value of n , allowing for network delay and any delay on the server in processing the connection. When the initial response is received from the server, the timer is set again for n seconds, to allow the initial handshake to complete.

For connections with the HandshakeRole parameter set to Server or ServerWithClientAuth, when the server starts to process the new connection the timer is set to n seconds, waiting for the initial request from the client. The timer is reset to n seconds when the server sends the initial response, to allow the initial handshake to complete.

If the timer expires, the TCP connection is reset. A value of 0 indicates that the connection does not time out waiting for the initial handshake to complete.

For TELNET connections a non-zero value is required.

HostReferenceIdDNS

Specifies a fully qualified DNS domain name for use in domain-based server certificate validation (with comparison logic defined by RFC 6125). As part of an SSL/TLS session negotiation, the client can verify that the received server certificate contains a Subject Alternative Name (SAN) extension with a DNS name that matches a reference value. A list of reference values is provided by specifying the HostReferenceIdDNS parameter one or more times for the client rule.

The *name* value should be a fully qualified domain name containing at least 3 labels, for example abc.example.com. It is not case sensitive.

If the HostReferenceIdDNS parameter is specified more than once, the values are concatenated to create a single list of domain names. For System SSL, the GSK_REFERENCE_ID_DNS value is set to a comma-separated list of names.

Restrictions:

- The maximum length of the comma-separated list provided to System SSL is 16384.
- The maximum length of a single name is 300.
- The name cannot contain an asterisk.

HostReferenceIdCN

Specifies a fully qualified DNS domain name for use in domain-based server certificate validation (with comparison logic defined by RFC 6125). As part of an SSL/TLS session negotiation, the client can verify that the received server certificate contains a subject DN common name with a DNS name that matches a reference value. A list of reference values is provided by specifying the HostReferenceIdCN parameter one or more times for the client rule.

The *name* value should be a fully qualified domain name containing at least 3 labels, for example abc.example.com. It is not case sensitive.

If the HostReferenceIdCN parameter is specified more than once, a comma-separated list of names is created. For System SSL, the GSK_REFERENCE_ID_CN value is set to the comma-separated list of names.

Restrictions:

- The maximum length of the comma-separated list provided to System SSL is 16384.
- The maximum length of a single name is 300.
- The name cannot contain an asterisk.
- If the server certificate contains a Subject Alternative Name (SAN) extension with a DNS domain name, the HostReferenceIdDNS parameter must be used for domain-based server certificate validation. The HostReferenceIdCN is provided for use with legacy certificates that do not include a SAN with a DNS domain name.

HostRefWildcardValidation

Specifies whether domain-based server certificate validation (with comparison logic defined by RFC 6125) is allowed when the DNS domain name from the certificate contains a wildcard ("*") in the first label of the DNS domain name. The DNS domain name could be from a

Subject Alternative Name (SAN) extension or from the DN common name. For System SSL, GSK_WILDCARD_VALIDATION_ENABLE is set to this value.

Off

Domain-based server certificate validation will fail if the server certificate contains a wildcard value in the DNS domain name.

On

Domain-based server certificate validation is allowed for a server certificate that contains a wildcard in the first label of the DNS domain name.

Restrictions:

- Validation will fail if a wildcard is found in any label of the DNS domain name other than the first or if the wildcard is the only character.
- The wildcard character will not be matched to more than one label.

ResetCipherTimer

Specifies the number of minutes a secure connection can be active before a new session key is generated for the connection. AT-TLS initiates a key update on the next read or write after the timer expires. For System SSL, the GSK_RESET_CIPHER function is used to initiate the key update.

For SSLv3, TLSv1.0, TLSv1.1, or TLSv1.2: A handshake is initiated on the next read or write after the timer expires. If the session ID has expired (controlled by the GSK_V3_SESSION_TIMEOUT statement), a full handshake is performed. Otherwise, a short handshake is performed.

For TLSv1.3 and later: A Key Update message is sent to the peer. The peer is also requested to change its application write key. The result is that the sender changes its application data write and read keys and the peer should change its corresponding application data read and write keys.

Valid values of *n* are in the range 0 - 1440. Specifying 0 means that the session key refresh is not initiated by AT-TLS for the life of the connection.

SecondaryMap

Specifies whether the application establishes secondary connections that should use the secondary policy mapping method. When specified in the TTLSConnectionAdvancedParms, this statement overrides the values specified in the TTLSEnvironmentAdvancedParms and TTLSGroupAdvancedParms. Valid values are:

Off

A connection that maps to this policy should not be used as a primary connection in the secondary policy mapping method.

On

A connection that maps to this policy should be used as a primary connection in the secondary policy mapping method. Future connections established between the same two IP addresses by the same process that do not map to any policy or map to a policy with a lower priority are considered secondary connections. These secondary connections use the same policy mapped by the associated primary connection.

ServerCertificateLabel

Specifies the label of the certificate for a server application to authenticate the server. A maximum of eight labels may be coded; each requiring a separate ServerCertificateLabel parameter. If multiple ServerCertificateLabel parameters are defined, the order in which they are defined is also the order of preference. The maximum length of value of the certificate label is 127 characters. The first certificate that meets the protocol/cipher criteria is chosen. For System SSL, the GSK_SERVER_KEYRING_LABEL_LIST is set to a comma-separated list of the values specified for all ServerCertificateLabel parameters.

Rule: Comment indicators and embedded blanks are treated as part of the value for this attribute. For example:

```
ServerCertificateLabel Root#CA Certificate
value used:    Root#CA Certificate
```

Restriction: When the value contains embedded blanks, you must specify the entire value within the first 1 536 characters of the configuration file line.

Tip: Using multiple certificates of the same key type is not advantageous unless a certificate early in the preference order is expected to expire soon and a certificate later in the order is expected to be the replacement certificate.

ServerExtendedMasterSecret

Specifies whether the TLS server supports the extended master secret (EMS) computation for TLSv1.0, TLSv1.1 and TLSv1.2 negotiations. This support is negotiated by the client and server. When the TLS server supports the EMS computation and receives an EMS extension on the Client Hello message, the server will include the EMS extension on the Server Hello message for a TLSv1.0, TLSv1.1, or TLSv1.2 handshake. The EMS extension is defined by RFC 7627.

Possible values are:

On

Specifies that the TLS server supports both clients that send an EMS extension, and those that do not.

Required

Specifies that the TLS server requires that clients send an EMS extension for a TLSv1.0, TLSv1.1, or TLSv1.2 handshake. If the client does not send the EMS extension, the handshake fails.

Off

Specifies that the TLS server does not support the EMS computation. The server will not send an EMS extension for a TLSv1.0, TLSv1.1, or TLSv1.2 handshake, even if it receives one from the client.

ServerHandshakeSNI

For TLSv1.0 protocol or later, this keyword specifies whether a certificate is chosen based on the server name list provided by the TLS client. For System SSL, the extension ID is set to GSK_TLS_SET_SNI_SERVER_SNAMEs and a flag is set in the gsk_tls_extension structure if it is required. Possible values are:

Required

Specifies that server name indication support must be accepted by the client. Connections fail if the client does not support server name indication.

Tip: When you specify ServerHandshakeSNI as Required, specify SSLv3 as Off.

Optional

Specifies that server name indication negotiation is supported, but allow connections with clients that do not support server name indication.

Off

Specifies that server name indication is not supported. The function is not enabled. Connections fail if the client requires support for server name indication.

ServerHandshakeSNIMatch

You must code this parameter when ServerHandshakeSNI is set to Required or Optional. For system SSL, a flag is set in the gsk_sni_server_labels structure if a match is required. Possible values are:

Required

Specifies that a server name in the list of server names provided by the TLS client must match a server name in the ServerHandshakeSNIList. The connection ends if no match can be found for the server name.

Optional

Specifies that connections to continue if no match is found for the server name.

ServerHandshakeSNIList

For SSL servers using TLSv1.0 protocol or later, this keyword specifies a server name and certificate label pair to be used by the server, separated by a slash (/). Multiple ServerHandshakeSNIList statements can be coded. The server matches the server name provided by the client to a certificate label. For System SSL, the server names and labels are anchored in the gsk_sni_server_labels

structure. A server name can be 1 - 255 characters in length. A certificate label can be 1 - 127 characters in length. This parameter is required when ServerHandshakeSNI is set to Required or Optional.

Rule: You can use comment indicators and embedded blanks as part of the certificate label value for this attribute. For example:

```
ServerHandshakeSNIList myservername/Root#CA Certificate  
value used: myservername/Root#CA Certificate
```

Restrictions:

- The total length of all the server names and certificate labels specified must be less than 32K.
- When the certificate label value contains embedded blanks, you must specify the entire parameter value within the first 1 536 characters of the configuration file line.

ServerMaxSSLFragment

For TLSv1.0 protocol or later, this keyword specifies whether the maximum SSL fragment function is supported when AT-TLS is the TLS server on the connection. For System SSL, the extension ID is set to GSK_TLS_SET_SERVER_MFL and a flag is set in the gsk_tls_extension structure if it is required. Possible values are:

Required

Specifies that maximum SSL fragment function support must be accepted by the client. Connections fail if the client does not support the maximum SSL fragment function.

Tip: When you specify ServerMaxSSLFragment as Required, specify SSLv3 as Off.

Optional

Specifies that support is provided for maximum SSL fragment function, but allow connections with clients that do not support the maximum SSL fragment function.

Off

Specifies that maximum SSL fragment function is not supported. The function is not enabled. Connections fail if the client requires support for maximum SSL fragment function.

SSLv2

Specifies the state of the SSL Version 2 protocol. For System SSL, the GSK_PROTOCOL_SSLV2 value is set to this value. Possible values are:

On

Enables the SSL Version 2 protocol.

Off

Disable the SSL Version 2 protocol.

SSLv3

Specifies the state of the SSL Version 3 protocol. For System SSL, the GSK_PROTOCOL_SSLV3 value is set to this value. Possible values are:

On

Enable the SSL Version 3 protocol.

Off

Disable the SSL Version 3 protocol.

TLSv1

Specifies the state of the TLS Version 1 protocol. For System SSL, the GSK_PROTOCOL_TLsv1 value is set to this value. Possible values are:

On

Enable the TLS Version 1.0 protocol.

Off

Disable the TLS Version 1.0 protocol.

TLsv1.1

Specifies the state of the TLS version 1.1 protocol. For System SSL, the GSK_PROTOCOL_TLsv1_1 value is set to this value. Possible values are:

On

Enable the TLS Version 1.1 protocol.

Off

Disable the TLS Version 1.1 protocol.

TLsv1.2

Specifies the state of the TLS version 1.2 protocol. For System SSL, the GSK_PROTOCOL_TLsv1_2 value is set to this value. Possible values are:

On

Enable the TLS Version 1.2 protocol.

Result: When you specify TLsv1.3 On for the TtlConnectionAdvancedParms statement, the default value for TLsv1.2 is Off. Otherwise, the default value for TLsv1.2 is inherited from the TtlEnvironmentAdvancedParms statement

Tip: When you specify TLsv1.2 as On, System SSL will not negotiate SSLv2 sessions even if you specify SSLv2 as On.

Off

Disable the TLS Version 1.2 protocol.

TLsv1.3

Specifies the state of the TLS version 1.3 protocol. For System SSL, the GSK_PROTOCOL_TLsv1_3 value is set to this value. Possible values are:

On

Enable the TLS Version 1.3 protocol.

Tip: When you specify TLsv1.3 as On, System SSL will not negotiate SSLv2 or SSLv3 sessions even if you specify SSLv2 or SSLv3 as On.

Off

Disable the TLS Version 1.3 protocol.

Tip: If TLsv1.3 is configured (with either On or Off) on the TtlConnectionAdvancedParms statement, configure the other TLS protocol versions on the TtlConnectionAdvancedParms as well.

Restriction: The FIPS 140-2 standard does not define support for TLsv1.3 or the new cipher suites defined for it. Enabling both the TLsv1.3 protocol and FIPS support results in an error.

Be aware that the CPU consumption of the TCP/IP address space likely increases when you enable TLsv1.3. While TLsv1.3 provides stronger cryptographic protection for your TCP connections, it inherently uses more cryptographic operations and therefore consumes more CPU than TLsv1.2 when using comparable cipher suites and key exchange algorithms. The magnitude of the CPU increase depends on a variety of factors, including the cipher suites you were using under TLsv1.2 (or earlier), the z/OS operating system level (earlier OS versions may not have as many optimizations as later versions), and the level of hardware you are using (earlier versions of hardware may have less cryptographic acceleration than newer versions).

TruncatedHMAC

For protocols TLsv1.0, TLsv1.1, and TLsv1.2 protocol, this keyword specifies whether clients and servers support the use of 80-bit truncated HMACs. For System SSL, the extension ID is set to GSK_TLS_EXTID_TRUNCATED_HMAC and a flag is set in the gsk_tls_extension structure if it is required. Possible values are:

Required

Specifies that 80-bit truncated HMAC support must be accepted by both endpoints. Connections fail if the remote endpoint does not support the 80-bit truncated HMAC.

Tip: When you specify TruncatedHMAC as Required, specify SSLv3 as Off.

Optional

Specifies that support is provided for 80-bit truncated HMAC negotiation, but connections with endpoints that do not support the truncated 80-bit HMAC are allowed.

Off

Specifies that support is not provided for 80-bit truncated HMAC negotiation. The function is not enabled. Connections fail if the remote endpoint requires support for the 80-bit truncated HMAC.

Result: The Truncated HMAC extension is not applicable for algorithms supported for the TLSv1.3 protocol. A server that attempts a TLSv1.3 protocol negotiation will not include the Truncated HMAC extension.

TTLSEnvironmentAction statement

Use the TTLSEnvironmentAction statement to specify the attributes for an AT-TLS environment. A TTLSEnvironmentAction statement is required if the TTLSGroupAction statement, referenced on the same TTLRule statement, specifies TTLSEnabled as **On**.

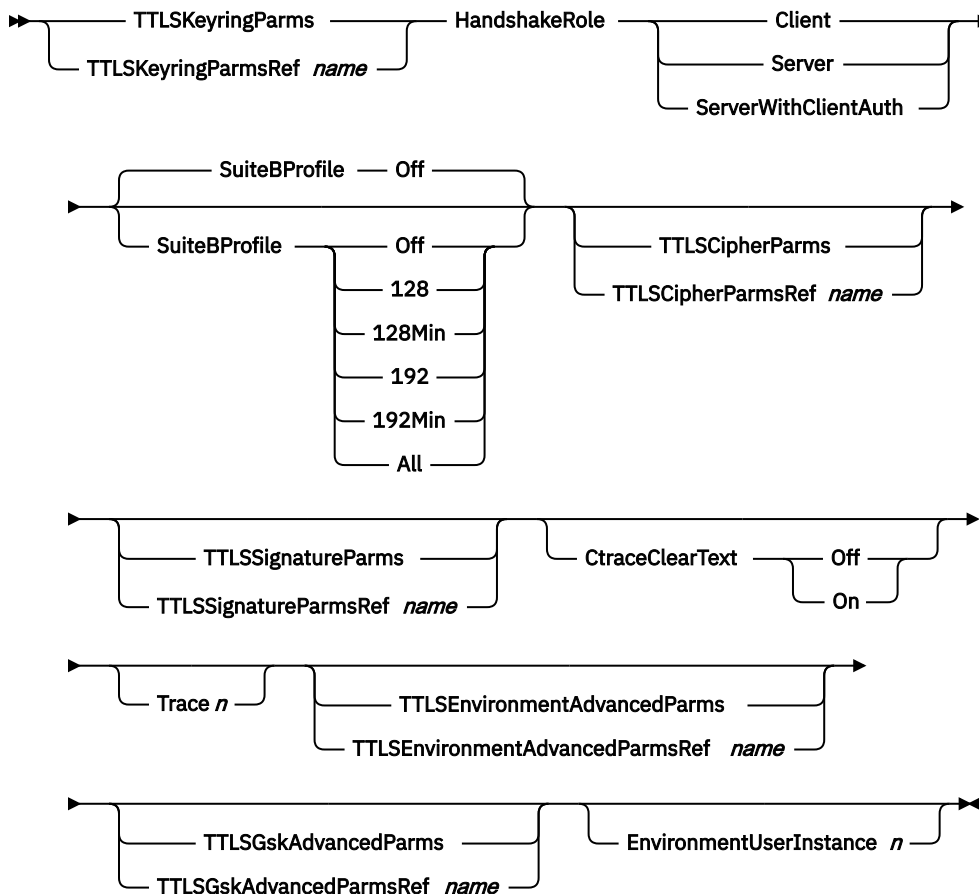

Syntax

➤➤ TTLSEnvironmentAction — *name* — Put Braces and Parameters on Separate Lines ➤➤

Put Braces and Parameters on Separate Lines

TTLSEnvironmentAction Parameters

Parameters

name

A string 1 - 32 characters in length specifying the name of this TTLSEnvironmentAction statement.

TTLSTKeyringParms

An inline specification of a TTLSTKeyringParms statement. This is a required parameter.

TTLSTKeyringParmsRef

The name of a globally defined TTLSTKeyringParms statement.

HandshakeRole

Specifies the SSL handshake role to be taken for connections in this AT-TLS environment. For System SSL, the GSK_SESSION_TYPE value is set to the same value as the HandshakeRole. This is a required parameter. Valid values are:

Client

Perform the SSL handshake as a client.

Server

Perform the SSL handshake as a server.

ServerWithClientAuth

Perform the SSL handshake as a server requiring client authentication.

SuiteBProfile

Specifies the RFC5430 Suite B cipher suites to apply to TLSv1.2 sessions. For more information on Suite B Profiles, see *Suite B cryptography support* in *z/OS Cryptographic Services System SSL Programming*. For System SSL, the GSK_SUITE_B_PROFILE value is set to the value of SuiteBProfile. Valid values are:

Off

The use of TLS V1.2 and Suite B cipher suites is not required. This is the default.

128

Suite B 128 bit cipher suites will be used.

128Min

AES-GCM ciphers with a minimum 128 bit strength will be used.

192

Suite B 192 bit cipher suites will be used.

192Min

AES-GCM ciphers with a minimum 192 bit strength will be used.

All

Both 128 bit and 192 bit Suite B cipher suites will be used.

Result: When 128, 128Min, 192, 192Min, or All is coded, any TTLSCTCipherParms statements are ignored. Only the ciphers that are defined in the Suite B profile will be used.

TTLSCTCipherParms

An inline specification of a TTLSCTCipherParms statement.

Tip: TTLSCTCipherParms statements are ignored if SuiteBProfile is specified with one of the following values: 128, 128Min, 192, 192Min, All. Only the ciphers that are defined in the Suite B profile will be used in those cases.

TTLSCTCipherParmsRef

The name of a globally defined TTLSCTCipherParms statement.

TTLSSTSignatureParms

An inline specification of a TTLSSTSignatureParms statement.

TTLSSTSignatureParmsRef

The name of a globally defined TTLSSTSignatureParms statement.

CtraceClearText

Specifies whether application data traced using Ctrace or data trace is shown as unencrypted data. This parameter is applied only to connections that have active AT-TLS security on the connection. If this value is specified on the TTLSEnvironmentAction statement, it is used instead of the value from the TTLSGroupAction statement referenced by the same TTLRule statement. Valid values are:

Off

Application data is not traced as clear text.

On

Application data is traced as clear text.

Trace

Specifies the level of AT-TLS tracing. The valid values for *n* are in the range 0 - 255. The sum of the numbers associated with each level of tracing selected is the value that should be specified as *n*. If *n* is an odd number, errors are written to joblog and all other configured traces are sent to syslogd. If this value is specified on the TTLSEnvironmentAction statement, it is used instead of the value from the TTLSGroupAction statement referenced by the same TTLRule statement.

Tip: The Trace parameter can be specified for the TTLSGroupAction, the TTLSEnvironmentAction, and the TTLSConnectionAction. To determine the value in effect for a TTLRule statement, examine each referenced action. The most specific action with the Trace parameter specified determines the value used. If the value is not specified for any of the referenced actions, the default value of 2 for the TTLSGroupAction is in effect.

0

No tracing is enabled.

1 (Error)

Errors are traced to the TCP/IP joblog

2 (Error)

Errors are traced to syslogd. The messages are issued with syslogd priority code **err**.

4 (Info)

Tracing of when a connection is mapped to an AT-TLS rule and when a secure connection is successfully initiated is enabled. The messages are issued with syslogd priority code **info**.

8 (Event)

Tracing of major events is enabled. The messages are issued with syslogd priority code **debug**.

16 (Flow)

Tracing of system SSL calls is enabled. The messages are issued with syslogd priority code **debug**.

32 (Data)

Tracing of encrypted negotiation and headers is enabled. This traces the negotiation of secure sessions. The messages are issued with syslogd priority code **debug**.

64

Reserved.

128

Reserved.

255

All tracing is enabled.

TTLSEnvironmentAdvancedParms

An inline specification of a TTLSEnvironmentAdvancedParms statement.

TTLSEnvironmentAdvancedParmsRef

The name of a globally defined TTLSEnvironmentAdvancedParms statement.

TTLSGskAdvancedParms

An inline specification of a TTLSGskAdvancedParms statement.

TTLSGskAdvancedParmsRef

The name of a globally defined TTLSGskAdvancedParms statement.

EnvironmentUserInstance

Defines a configurable instance identifier for this TTLSEnvironmentAction statement. The *n* value can be in the range 0 - 65535. This parameter can be used to signal a change to the Policy Agent without modifying any of the other AT-TLS configuration statements. For example, when the contents of the key ring has changed, but the key ring name is unchanged. Adding or updating the EnvironmentUserInstance parameter would signal Policy Agent to install a new TTLSEnvironmentAction statement. This parameter can also be used as a field to be updated when a change is made to this TTLSEnvironmentAction statement. This enables the user to differentiate TTLSEnvironmentAction statements, based on the instance identifier.

TTLSEnvironmentAdvancedParms statement

Use the TTLSEnvironmentAdvancedParms statement to specify advanced attributes for an AT-TLS environment.

Syntax

Put Braces and Parameters on Separate Lines

TTLSEnvironmentAdvancedParms Parameters

Parameters

name

A string 1 - 32 characters in length specifying the name of this TTLSEnvironmentAdvancedParms statement.

Rule: If this TTLSEnvironmentAdvancedParms statement is not specified inline within another statement, a *name* value must be provided. If a name value is not specified for an inlineTTLSEnvironmentAdvancedParms statement, a nonpersistent system name is created.

3DesKeyCheck

Specifies that when Triple DES session key are generated, each key part must be unique. For System SSL, the GSK_3DES_KEYCHECK is set to this value. Valid values are:

Off

When operating in non-FIPS mode the key parts are not compared for uniqueness. Key uniqueness is always enforced in FIPS mode. This is the default.

On

Key parts are compared for uniqueness.

ApplicationControlled

Specifies whether the application can control AT-TLS security for a connection. Valid values are:

Off

An application cannot control AT-TLS security. The connection automatically negotiates AT-TLS security. This is the default.

On

An application can control AT-TLS security. AT-TLS security is used only when requested by the application, using the SIOCTTLCTL ioctl.

CertificateLabel

Specifies the label of the certificate to be used for authentication. Valid values are in the range 1 - 127 characters in length. For System SSL, the GSK_KEYRING_LABEL value is set to this value.

Rule: Comment indicators and embedded blanks are treated as part of the value for this attribute. For example:

```
CertificateLabel Root#CA Certificate
value used:    Root#CA Certificate
```

Restriction: When the value contains embedded blanks, you must specify the entire value within the first 1 536 characters of the configuration file line.

CertValidationMode

Specifies the method of certificate validation. For System SSL, the GSK_CERT_VALIDATION_MODE value is set to this value. Possible values are:

Any

Specifies that certificate validation can use any supported X.509 certificate validation method. This is the default.

RFC2459

Specifies that certificates are validated by using the method described in RFC 2459.

RFC3280

Specifies that certificates are validated by using the method described in RFC 3280.

RFC5280

Specifies that certificates are validated by using the method described in RFC 5280.

Results: If 128-bit minimum or 192-bit minimum Suite B profiles are configured, the CertValidationMode setting is ignored and the certificate validation method described in RFC 5280 and RFC 5759 is used.

ClientAuthType

Specifies the type of client certificate validation to be performed for connections in this AT-TLS environment. Client certificates are requested only if HandshakeRole is set to **ServerWithClientAuth**. Valid values are:

PassThru

Bypasses client certificate validation.

Full

Performs client certificate validation if the client presents a certificate.

Required

Requires the client to present a certificate and performs client certificate validation. This is the default.

SAFCheck

Requires the client to present a certificate, performs client certificate validation and requires the client certificate to have an associated user ID defined to the security product.

ClientEDHGroupSize

Specifies the minimum accepted server Diffie-Hellman group size allowed for an ephemeral Diffie-Hellman key exchange message when AT-TLS is the TLS client. For System SSL, GSK_CLIENT_EPHEMERAL_DH_GROUP_SIZE is set to this value. Valid values are:

Legacy

Enforce minimum group size of 1024 for each new server handshake in non-FIPS mode and group size of 2048 when operating in FIPS mode. This is the default.

2048

Enforce minimum group size of 2048 for each new server handshake.

ClientExtendedMasterSecret

Specifies whether the TLS client supports the extended master secret (EMS) computation for TLSv1.0, TLSv1.1 and TLSv1.2 negotiations. This support is negotiated by the client and server. When the TLS client supports the EMS computation, it will include the EMS extension on the Client Hello message if TLSv1.0, TLSv1.1, or TLSv1.2 is enabled. If the server also supports the EMS computation, it will include the EMS extension on the Server Hello message for a TLSv1.0, TLSv1.1, or TLSv1.2 negotiation. The EMS extension is defined by RFC 7627.

Possible values are:

On

Specifies that the TLS client (when enabled for TLSv1.0, TLSv1.1, or TLSv1.2) will send an EMS extension to the server. If the server responds with an EMS extension for a TLSv1.0, TLSv1.1, or TLSv1.2 handshake, the EMS computation will be used. If the server does not send an EMS extension the handshake can still succeed but the standard master secret derivation is used. This is the default.

Required

Specifies that the TLS client (when enabled for TLSv1.0, TLSv1.1, or TLSv1.2) will send an EMS extension to the server and requires that the server respond with an EMS extension for a TLSv1.0, TLSv1.1, or TLSv1.2 handshake. If the server does not indicate support by sending the EMS extension, the handshake fails.

Off

Specifies that the TLS client (when enabled for TLSv1.0, TLSv1.1, or TLSv1.2) will not send the EMS extension to the server during the handshake.

ClientHandshakeSNI

For TLSv1.0 protocol and later, this keyword specifies whether a client can specify a list of server names. The server chooses a certificate based on that server name list for this connection. For System SSL, the extension ID is set to GSK_TLS_SET_SNI_CLIENT_SNAMES and a flag is set in the gsk_tls_extension structure if it is required. Valid values are:

Required

Specifies that server name indication support must be accepted by the server. Connections fail if the server does not support server name indication.

Tip: When you specify ClientHandshakeSNI as required, specify SSLv3 as Off.

Optional

Specifies that server name indication negotiation is supported, but allows connections with servers that do not support server name indication negotiation.

Off

Specifies that server name indication is not supported. The function is not enabled. Connections fail if the server requires support for server name indication. This is the default.

ClientHandshakeSNIMatch

Code this parameter if ClientHandshakeSNI is set to Required or Optional. For system SSL, a flag is set in the gsk_sni_client_snames structure if a match is required. Possible values are:

Required

Specifies that a server name in the list of server names provided by the TLS client must match a server name in the list of server names and certificate labels on the TLS server. The connection ends if no match was found for the server name at the server.

Optional

Specifies that connections can continue if no match is found for the server name.

ClientHandshakeSNIList

For SSL clients using TLSv1.0 protocol and later, this keyword specifies a server name. You can code multiple ClientHandshakeSNIList statements. The list of server names is passed to the server in the SSL handshake. For System SSL, the server names are anchored in the gsk_sni_client_snames structure. A server name can be 1 - 255 characters in length. This parameter is required when ClientHandshakeSNI is set to Required or Optional.

Restriction: The total length of all the server names specified must be less than 32K.

ClientMaxSSLFragment

For TLSv1.0 protocol and later, this keyword specifies whether maximum SSL fragment function is supported when AT-TLS is the TLS client on the connection. For System SSL, the extension ID is set to GSK_TLS_SET_CLIENT_MFL and a flag is set in the gsk_tls_extension structure if it is required. Possible values are:

Required

Specifies that maximum SSL fragment function support must be accepted by the server. Connections fail if the server does not support maximum SSL fragment function.

Tip: When you specify ClientMaxSSLFragment as Required, specify SSLv3 as Off.

Optional

Specifies support for maximum SSL fragment function negotiation, but allows connections with servers that do not support maximum SSL fragment function.

Off

Specifies that maximum SSL fragment function negotiation is not supported. The function is not enabled. Connections fail if the server requires support for maximum SSL fragment function. This is the default.

ClientMaxSSLFragmentLength

For TLSv1.0 protocol and later, this value specifies maximum SSL fragment function, in bytes, to request on the connection when AT-TLS is the TLS client using TLSv1.0 and TLSv1.1 protocols. The valid values are 512, 1024, 2048, and 4096. For System SSL, the maximum fragment length is set to GSK_TLS_MFL_512, GSK_TLS_MFL_1024, GSK_TLS_MFL_2048, or GSK_TLS_MFL_4096. This parameter is required when ClientMaxSSLFragment is set to Required or Optional.

HandshakeTimeout

Specifies the number of seconds to wait for the initial handshake to complete. Valid values of *n* are in the range 0 - 600. The default value is 10.

For connections with the HandshakeRole parameter set to Client, the timer is initially set to 5 times the value of n , allowing for network delay and any delay on the server in processing the connection. When the initial response is received from the server, the timer is set again for n seconds, to allow the initial handshake to complete.

For connections with that HandshakeRole parameter set to Server or ServerWithClientAuth, when the server starts to process the new connection the timer is set to n seconds, waiting for the initial request from the client. The timer is reset to n seconds when the server sends the initial response, to allow the initial handshake to complete.

If the timer expires, the TCP connection is reset. A value of 0 indicates that the connection does not time out waiting for the initial handshake to complete.

For TELNET connections a non-zero value is required.

HostReferenceIdDNS

Specifies a fully qualified DNS domain name for use in domain-based server certificate validation (with comparison logic defined by RFC 6125). As part of an SSL/TLS session negotiation, the client can verify that the received server certificate contains a Subject Alternative Name (SAN) extension with a DNS name that matches a reference value. A list of reference values is provided by specifying the HostReferenceIdDNS parameter one or more times for the client rule.

The *name* value should be a fully qualified domain name containing at least 3 labels, for example abc.example.com. It is not case sensitive.

If the HostReferenceIdDNS parameter is specified more than once, a comma-separated list of names is created. For System SSL, the GSK_REFERENCE_ID_DNS value is set to the comma-separated list of names.

If neither HostReferenceIdDNS nor HostReferenceIdCN is configured, domain-based server certificate validation is not done.

Restrictions:

- The maximum length of the comma-separated list provided to System SSL is 16384.
- The maximum length of a single name is 300.
- The name cannot contain an asterisk.

HostReferenceIdCN

Specifies a fully qualified DNS domain name for use in domain-based server certificate validation (as defined by RFC 6125). As part of an SSL/TLS session negotiation, the client can verify that the received server certificate contains a subject DN common name with a DNS name that matches a reference value. A list of reference values is provided by specifying the HostReferenceIdCN parameter one or more times for the client rule.

The *name* value should be a fully qualified domain name containing at least 3 labels, for example abc.example.com. It is not case sensitive.

If the HostReferenceIdCN parameter is specified more than once, a comma-separated list of names is created. For System SSL, the GSK_REFERENCE_ID_CN value is set to the comma-separated list of names.

If neither HostReferenceIdDNS nor HostReferenceIdCN is configured, domain-based server certificate validation is not done.

Restrictions:

- The maximum length of the comma-separated list provided to System SSL is 16384.
- The maximum length of a single name is 300.
- The name cannot contain an asterisk.
- If the server certificate contains a Subject Alternative Name (SAN) extension with a DNS domain name, the HostReferenceIdDNS parameter must be used for domain-based server certificate

validation. The Host ReferenceIdCN is provided for use with legacy certificates that do not include a SAN with a DNS domain name.

HostRefWildcardValidation

Specifies whether domain-based server certificate validation (with comparison logic defined by RFC 6125) is allowed when the DNS domain name from the certificate contains a wildcard ("*") in the first label of the DNS domain name. The DNS domain name could be from a Subject Alternative Name (SAN) extension or from the DN common name. For System SSL, GSK_WILDCARD_VALIDATION_ENABLE is set to this value.

Off

Domain-based server certificate validation will fail if the server certificate contains a wildcard value in the DNS domain name.

On

Domain-based server certificate validation is allowed for a server certificate that contains a wildcard in the first label of the DNS domain name.

Restrictions:

- Validation will fail if a wildcard is found in any label of the DNS domain name other than the first or if the wildcard is the only character.
- The wildcard character will not be matched to more than one label.

MiddleBoxCompatMode

Specifies whether the TLSv1.3 handshake process should use or tolerate handshake messages in a manner compliant with earlier TLS protocols to alleviate possible issues with middle boxes or proxies. For System SSL, the GSK_MIDDLEBOX_COMPAT_MODE value is set to this value. Possible values are:

On

For a TLSv1.3 handshake, send handshake messages in a manner compliant with earlier TLS protocols.

Off

For a TLSv1.3 handshake, use the TLSv1.3 handshake format. This is the default.

Tip: RFC 8446 reports that a number of middleboxes were found to drop TLSv1.3 handshake messages. Using the compatibility mode increases the chance of a successful negotiation since the TLSv1.3 handshake will use handshake messages in a manner compliant with earlier TLS protocols.

PeerMinCertVersion

Specifies a minimum X.509 version level for the partner's end-entity certificate. For System SSL, GSK_PEER_CERT_MIN_VERSION is set to this value. Valid values are:

Any

Any supported X.509 version supported by System SSL. This is the default.

3

The minimum X.509 version is version 3.

Result: If the negotiated protocol is TLSv1.3, it requires a X.509 version 3 certificate. This parameter is ignored.

PeerMinDHKeySize

Specifies the minimum allowed X.509 certificate Diffie-Hellman key size for a peer end-entity certificate. For System SSL, GSK_PEER_DH_MIN_KEY_SIZE is set to this value. Valid values are 0 - 2048. Any value specified that does not equal a supported key size increment will set the minimum key size to the next highest increment. The default value is 1024. In FIPS mode, setting can be used to enforce stronger DH key sizes than the default defined by FIPS mode.

PeerMinDsaKeySize

Specifies the minimum allowed X.509 certificate DSA key size for a peer end-entity certificate. For System SSL, GSK_PEER_DSA_MIN_KEY_SIZE is set to this value. Valid values are 0 - 2048. Any value specified that does not equal a supported key size increment will set the minimum key size to the next highest increment. The default value is 1024. In FIPS mode, setting can be used to enforce stronger DSA key sizes than the default defined by FIPS mode.

PeerMinECCKeysize

Specifies the minimum allowed X.509 certificate ECC key size for a peer end-entity certificate. For System SSL, GSK_PEER_ECC_MIN_KEY_SIZE is set to this value. Valid values are 0 - 521. Any value specified that does not equal a supported key size increment will set the minimum key size to the next highest increment. The default value is 192. In FIPS mode, setting can be used to enforce stronger ECC key sizes than the default defined by FIPS mode.

PeerMinRsaKeySize

Specifies the minimum allowed X.509 certificate RSA key size for a peer end-entity certificate. For System SSL, GSK_PEER_RSA_MIN_KEY_SIZE is set to this value. Valid values are 0 - 4096. Any value specified that does not equal a supported key size increment will set the minimum key size to the next highest increment. The default value is 1024. In FIPS mode, setting can be used to enforce stronger RSA key sizes than the default defined by FIPS mode.

ResetCipherTimer

Specifies the number of minutes a secure connection can be active before a new session key is generated for the connection. AT-TLS initiates a key update on the next read or write after the timer expires. For System SSL, the GSK_RESET_CIPHER function is used to initiate this.

For SSLv3, TLSv1.0, TLSv1.1, or TLSv1.2: A handshake is initiated on the next read or write after the timer expires. If the session ID has expired (controlled by the GSK_V3_SESSION_TIMEOUT statement), a full handshake is performed. Otherwise, a short handshake is performed.

For TLSv1.3 and later: A Key Update message is sent to the peer. The peer is also requested to change its application write key. The result is that the sender changes its application data write and read keys and the peer should change its corresponding application data read and write keys.

Valid values of *n* are in the range 0 - 1440. Specifying 0 means that session key refresh is not initiated by AT-TLS for the life of the connection. The default value is 0.

Renegotiation

Specifies the type of session key renegotiation that is allowed. For System SSL, the GSK_RENEGOTIATION value is set. The following values are valid:

Default

GSK_RENEGOTIATION set to NONE. Disables SSL V3 and TLS handshake renegotiation as a server and allows RFC 5746 renegotiation. This is the default.

Disabled

Disables SSL V3 and TLS handshake renegotiation as a server and disables RFC 5746 renegotiation.

All

Allows SSL V3 and TLS handshake renegotiation as a server and allows RFC 5746 renegotiation.

Abbreviated

Allows SSL V3 and TLS abbreviated handshake renegotiation as a server for resuming the current session only, while disabling SSL V3 and TLS full handshake renegotiation as a server. The System SSL session ID cache is not checked when resuming the current session. Allows RFC 5746 renegotiation.

Result: If the negotiated protocol is TLSv1.3, renegotiation is not allowed. This parameter is ignored.

RenegotiationIndicator

Sets the enforcement level of the initial handshake renegotiation indication as RFC 5746 specifies. For System SSL, the GSK_EXTENDED_RENEGOTIATION_INDICATOR value is set to this value. The following values are valid:

Optional

The renegotiation indicator is not required during initial handshake.

Client

Allow the client initial handshake to proceed only when the server indicates support for RFC 5746 renegotiation.

Server

Allow the server initial handshake to proceed only when the client indicates support for RFC 5746 renegotiation.

Both

Allow the client and server initial handshakes to proceed only when the partner indicates support for RFC 5746 renegotiation.

Result: If the negotiated protocol is TLSv1.3, renegotiation is not allowed. This parameter is ignored.

RenegotiationCertCheck

Specifies whether to perform an identity check against the peer's certificate during renegotiation. For System SSL, the GSK_RENEGOTIATION_PEER_CERT_CHECK value is set to this value. Valid values are:

Off

An identity check is not performed. This allows the peer certificate to change during renegotiation.

On

An identity check is performed. This ensures that the peer certificate does not change during renegotiation.

Result: If the negotiated protocol is TLSv1.3, renegotiation is not allowed. This parameter is ignored.

SecondaryMap

Specifies whether the application establishes secondary connections that should use the secondary policy mapping method. When specified in the TTLSEnvironmentAdvancedParms, this statement overrides the value specified in the TTLSGroupAdvancedParms. Valid values are:

Off

A connection that maps to this policy should not be used as a primary connection in the secondary policy mapping method.

On

A connection that maps to this policy should be used as a primary connection in the secondary policy mapping method. Future connections established between the same two IP addresses by the same process that do not map to any policy or map to a policy with a lower priority are considered secondary connections. These secondary connections use the same policy mapped by the associated primary connection.

ServerCertificateLabel

Specifies the label of the certificate for a server application to authenticate the server. A maximum of eight labels may be coded; each requiring a separate ServerCertificateLabel parameter. If multiple ServerCertificateLabel parameters are defined, the order they are defined is also the order of preference. The maximum length of value of the certificate label is 127 characters. The first certificate that meets the protocol/cipher criteria is chosen. For System SSL, the GSK_SERVER_KEYRING_LABEL_LIST is set to a comma-separated list of the values specified for all ServerCertificateLabel parameters.

Rule: Comment indicators and embedded blanks are treated as part of the value for this attribute. For example:

```
ServerCertificateLabel Root#CA Certificate
value used: Root#CA Certificate
```

Restriction: When the value contains embedded blanks, you must specify the entire value within the first 1 536 characters of the configuration file line.

Tip: Using multiple certificates of the same key type is not advantageous unless a certificate early in the preference order is expected to expire soon and a certificate later in the order is expected to be the replacement certificate.

ServerExtendedMasterSecret

Specifies whether the TLS server supports the extended master secret (EMS) computation for TLSv1.0, TLSv1.1 and TLSv1.2 negotiations. This support is negotiated by the client and server. When

the TLS server supports the EMS computation and receives an EMS extension on the Client Hello message, the server will include the EMS extension on the Server Hello message for a TLSv1.0, TLSv1.1, or TLSv1.2 handshake. The EMS extension is defined by RFC 7627.

Possible values are:

On

Specifies that the TLS server supports both clients that send an EMS extension, and those that do not. This is the default.

Required

Specifies that the TLS server requires that clients send an EMS extension for a TLSv1.0, TLSv1.1, or TLSv1.2 handshake. If the client does not send the EMS extension, the handshake fails.

Off

Specifies that the TLS server does not support the EMS computation. The server will not send an EMS extension for a TLSv1.0, TLSv1.1, or TLSv1.2 handshake, even if it receives one from the client.

ServerHandshakeSNI

For TLSv1.0 protocol and later, this keyword specifies whether a certificate is chosen based on the server name list provided by the TLS client. For System SSL, the extension ID is set to GSK_TLS_SET_SNI_SERVER_SNAMEs and a flag is set in the gsk_tls_extension structure if it is required. Possible values are:

Required

Specifies that server name indication support must be accepted by the client. Connections fail if the client does not support server name indication.

Tip: When you specify ServerHandshakeSNI as Required, specify SSLv3 as Off.

Optional

Specifies that server name indication negotiation is supported, but allow connections with clients that do not support server name indication.

Off

Specifies that server name indication is not supported. The function is not enabled. Connections fail if the client requires support for server name indication. This is the default value.

ServerHandshakeSNIMatch

You must code this parameter when ServerHandshakeSNI is set to Required or Optional. For system SSL, a flag is set in the gsk_sni_server_labels structure if a match is required. Possible values are:

Required

Specifies that a server name in the list of server names provided by the TLS client must match a server name in the ServerHandshakeSNIList. The connection ends if no match can be found for the server name.

Optional

Specifies that connections continue if no match is found for the server name.

ServerHandshakeSNIList

For SSL servers using TLSv1.0 protocol and later, this keyword specifies a server name and certificate label pair to be used by the server, separated by a slash (/). Multiple ServerHandshakeSNIList statements can be coded. The server matches the server name provided by the client to a certificate label. For System SSL, the server names and labels are anchored in the gsk_sni_server_labels structure. A server name can be 1 - 255 characters in length. A certificate label can be 1 - 127 characters in length. This parameter is required when ServerHandshakeSNI is set to Required or Optional.

Rule: You can use comment indicators and embedded blanks as part of the certificate label value for this attribute. For example:

```
ServerHandshakeSNIList myservername/Root#CA Certificate
value used: myservername/Root#CA Certificate
```

Restrictions:

- The total length of all the server names and certificate labels specified must be less than 32K.
- When the certificate label value contains embedded blanks, you must specify the entire parameter value within the first 1 536 characters of the configuration file line.

ServerMaxSSLFragment

For TLSv1.0 protocol and later, this keyword specifies whether the maximum SSL fragment function is supported when AT-TLS is the TLS server on the connection. For System SSL, the extension ID is set to GSK_TLS_SET_SERVER_MFL and a flag is set in the gsk_tls_extension structure if it is required. Possible values are:

Required

Specifies that maximum SSL fragment function support must be accepted by the client. Connections fail if the client does not support maximum SSL fragment function.

Tip: When you specify ServerMaxSSLFragment as Required, specify SSLv3 as Off.

Optional

Specifies that support is provided for maximum SSL fragment function, but allow connections with clients that do not support maximum SSL fragment function.

Off

Specifies that maximum SSL fragment function is not supported. The function is not enabled. Connections fail if the client requires support for maximum SSL fragment function. This is the default value.

ServerEDHGroupSize

Specifies the minimum server Diffie-Hellman group size allowed for an ephemeral Diffie-Hellman key exchange message when AT-TLS is the TLS server. For System SSL, GSK_SERVER_EPHEMERAL_DH_GROUP_SIZE is set to this value. Valid values are:

Legacy

Utilize minimum group size of 1024 for each new handshake in non-FIPS mode and group size of 2048 when operating in FIPS mode. This is the default.

2048

Utilize minimum group size of 2048 for each new handshake.

Match

Match the ephemeral Diffie-Hellman group to the server certificate's key strength. If the key size is less than or equal to 1024, a group size of 1024 will be used. If the key size is greater than 1024, then a group size of 2048 will be used.

Result: When a value of Legacy or 2048 is configured, a defined set of Diffie-Hellman parameters is used to generate a unique key. When a value of Match is configured, System SSL generates the Diffie-Hellman parameters that are used to generate a unique key. The additional processing to generate the Diffie-Hellman parameters is done in software and can be CPU-intensive.

ServerScsv

Specifies support for honoring the Signaling Cipher Suite Value (SCSV) when included in the TLS client's cipher list. When the SCSV is specified in the TLS client's cipher list, it indicates that the handshake is a fallback attempt. For System SSL, the GSK_SERVER_FALLBACK_SCSV is set to this value. Valid values are:

Off

Support disabled for the Signaling Cipher Suite Value. This is the default.

On

Support enabled for the Signaling Cipher Suite Value.

SSLv2

Specifies the state of the SSL Version 2 protocol. For System SSL, the GSK_PROTOCOL_SSLV2 value is set to this value. Possible values are:

On

Enables the SSL Version 2 protocol.

Off

Disables the SSL Version 2 protocol. This is the default.

SSLv3

Specifies the state of the SSL Version 3 protocol. For System SSL, the GSK_PROTOCOL_SSLV3 value is set to this value. Possible values are:

On

Enable the SSL Version 3 protocol.

Off

Disable the SSL Version 3 protocol. This is the default.

TLSv1

Specifies the state of the TLS Version 1 protocol. For System SSL, the GSK_PROTOCOL_TLSV1 value is set to this value. Possible values are:

On

Enable the TLS Version 1.0 protocol.

Off

Disable the TLS Version 1.0 protocol. This is the default.

TLSv1.1

Specifies the state of the TLS Version 1.1 protocol. For System SSL, the GSK_PROTOCOL_TLSV1_1 value is set to this value. Possible values are:

On

Enable the TLS Version 1.1 protocol.

Off

Disable the TLS Version 1.1 protocol. This is the default.

TLSv1.2

Specifies the state of the TLS Version 1.2 protocol. For System SSL, the GSK_PROTOCOL_TLSV1_2 value is set to this value. Possible values are:

On

Enable the TLS Version 1.2 protocol.

Tip: When you specify TLSv1.2 as On, System SSL will not negotiate SSLv2 sessions even if you specify SSLv2 as On.

Off

Disable the TLS Version 1.2 protocol.

Result: When you specify TLSv1.3 as On, the default value for TLSv1.2 is Off. Otherwise, the default value for TLSv1.2 is On.

TLSv1.3

Specifies the state of the TLS Version 1.3 protocol. For System SSL, the GSK_PROTOCOL_TLSV1_3 value is set to this value. Possible values are:

On

Enable the TLS Version 1.3 protocol.

Tip: When you specify TLSv1.3 as On, System SSL will not negotiate SSLv2 or SSLv3 sessions even if you specify SSLv2 or SSLv3 as On.

Result: When you specify TLSv1.3 as On, the default value for TLSv1.2 is Off.

Off

Disable the TLS Version 1.3 protocol. This is the default.

Restriction: The FIPS 140-2 standard does not define support for TLSv1.3 or the new cipher suites defined for it. Enabling both the TLSv1.3 protocol and FIPS support results in an error.

Be aware that the CPU consumption of the TCP/IP address space will likely increase when you enable TLSv1.3. While TLSv1.3 provides stronger cryptographic protection for your TCP connections, it inherently uses more cryptographic operations and therefore consumes more CPU than TLSv1.2 when using comparable cipher suites and key exchange algorithms. The magnitude of the CPU increase depends on a variety of factors, including the cipher suites you were using under TLSv1.2 (or earlier), the z/OS operating system level (earlier OS versions may not have as many optimizations as later versions), and the level of hardware you are using (earlier versions of hardware may have less cryptographic acceleration than newer versions).

TruncatedHMAC

For protocols TLSv1.0, TLSv1.1, and TLSv1.2 protocol, this keyword specifies whether clients and servers support the use of 80-bit truncated HMACs. For System SSL, the extension ID is set to GSK_TLS_EXTID_TRUNCATED_HMAC and a flag is set in the gsk_tls_extension structure, if it is required. Possible values are:

Required

Specifies that 80-bit truncated HMAC support must be accepted by both endpoints. Connections fail if the remote endpoint does not support the 80-bit truncated HMAC.

Tip: When you specify TruncatedHMAC as Required, specify SSLv3 as Off.

Optional

Specifies that support is provided for 80-bit truncated HMAC negotiation, but connections with endpoints that do not support the truncated 80-bit HMAC are allowed.

Off

Specifies that support is not provided for 80-bit truncated HMAC negotiation. The function is not enabled. Connections fail if the remote endpoint requires support for the 80-bit truncated HMAC. This is the default.

Result: The Truncated HMAC extension is not applicable for algorithms supported for the TLSv1.3 protocol. A server that attempts a TLSv1.3 protocol negotiation will not include the Truncated HMAC extension.

TTLSTLSGroupAction statement

Use the TTLSTLSGroupAction statement to specify parameters for a Language Environment process required to support secure connections. The TTLSTLSGroupAction statement indicates whether a selected connection should use AT-TLS security. It can also specify the environment variables the Language Environment process should be initiated with.

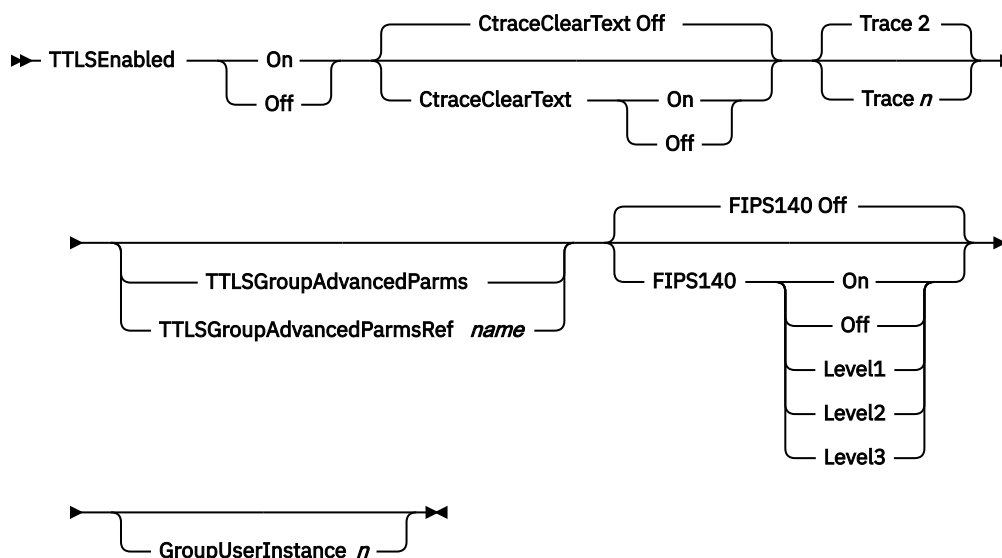

Syntax

➤ TTLSTLSGroupAction — *name* — Put Braces and Parameters on Separate Lines ➤

Put Braces and Parameters on Separate Lines

TTLSTLSGroupAction Parameters

Parameters

name

A string 1 - 32 characters in length specifying the name of this TTLSGroupAction statement.

TTLSEnabled

Indicates the action that should be applied to connections using this TTLSGroupAction statement.

On

AT-TLS security is active. Data might be encrypted, based on other policy statements.

Off

AT-TLS security is not active. Data is sent in the clear.

CtraceClearText

Specifies whether application data traced using Ctrace or data trace is shown as unencrypted data. This parameter is applied only to connections that have active AT-TLS security on the connection. CtraceClearText can be specified on multiple actions referenced by a common TTLSRule statement. The value specified on the TTLSGroupAction statement can be overridden for particular AT-TLS environments by specifying it on the TTLSEnvironmentAction statement, or for particular connections by specifying it on the TTLSConnectionAction statement. Valid values are:

Off

Application data is not traced as clear text. This is the default.

On

Application data is traced as clear text.

Trace

Specifies the level of AT-TLS tracing. The valid values for *n* are in the range 0 - 255. The sum of the numbers associated with each level of tracing selected is the value that should be specified as *n*. If *n* is an odd number, errors are written to joblog and all other configured traces are sent to syslogd.

The trace parameter can be specified on multiple actions referenced by a common TTLSRule statement. The value specified on the TTLSGroupAction statement can be overridden for particular AT-TLS environments by specifying it on the TTLSEnvironmentAction statement or for particular connections by specifying it on the TTLSConnectionAction statement.

0

No tracing is enabled.

1 (Error)

Errors are traced to the TCP/IP joblog.

2 (Error)

Errors are traced to syslogd. This is the default. The messages are issued with syslogd priority code **err**.

4 (Info)

Tracing of instances when a connection is mapped to an AT-TLS rule and when a secure connection is successfully initiated is enabled. The messages are issued with syslogd priority code **info**.

8 (Event)

Tracing of major events is enabled. The messages are issued with syslogd priority code **debug**.

16 (Flow)

Tracing of system SSL calls is enabled. The messages are issued with syslogd priority code **debug**.

32 (Data)

Tracing of encrypted negotiation and headers is enabled. This traces the negotiation of secure sessions. The messages are issued with syslogd priority code **debug**.

64

Reserved.

128

Reserved.

255

All tracing is enabled.

TTLSTGroupAdvancedParms

An inline specification of a TTLSTGroupAdvancedParms statement.

TTLSTGroupAdvancedParmsRef

The name of a globally defined TTLSTGroupAdvancedParms statement.

FIPS140

Specifies whether FIPS 140 support is enabled for this group. Enabling FIPS 140 mode provides a higher degree of assurance of the integrity of the cryptographic modules that AT-TLS uses, including ICSF and System SSL. However, enabling FIPS 140 mode might require additional setup and configuration and it will restrict the available set of cryptographic algorithms. Valid values are:

Off

Indicates that FIPS 140 is not supported for this group. This is the default.

On

Indicates that FIPS 140 is supported for this group and is enforcing 80 bit security strength size for all operations.

Level1

Functionally equivalent to 'On'.

Level2

Indicates that FIPS 140 is supported for this group and is utilizing 112 bit security strength size when generating new keys, digital signatures, and RSA encryption. However, it allows 80 bit security when performing digital signature verification, RSA decryption and Triple DES decryption when processing information that was protected by the TLS peer.

Level3

Indicates that FIPS 140 is supported for this group and is enforcing 112 bit or higher security strength size for all operations. 80 bit security strength size is not allowed for any operation.

Requirement: ICSF must be active before starting AT-TLS groups configured to support FIPS140. For information about configuring ICSF to support FIPS 140-2, see [Operating in compliance with FIPS 140-2 in z/OS Cryptographic Services ICSF Writing PKCS #11 Applications](#).

If the CSFSERV class is defined, give the userID that is associated with the TCPIP stack and any application userID using the TTLSTGroup READ access to the CSFRNG resource within the RACF CSFSERV class. If the CSFSERV class is defined and Diffie Hellman is being used, give the application

userID READ access to the CSF1TRC, CSF1DVK, CSF1GKP, CSF1GSK, CSF1GAV, and CSF1TRD resources within the RACF CSFSERV class.

Restriction: The FIPS 140-2 standard does not define support for TLSv1.3 or the new cipher suites defined for it. Enabling both the TLSv1.3 protocol and FIPS support results in an error.

GroupUserInstance

Defines a configurable instance identifier for this TTLSGroupAction statement. The *n* value can be in the range 0 - 65535. This parameter can be used to signal a change to the Policy Agent without modifying any of the other AT-TLS configuration statements. For example, when the contents of the Envfile has changed, but the Envfile file name is unchanged. Adding or updating the GroupUserInstance parameter would signal policy agent to install a new TTLSGroupAction statement. This parameter can also be used as a field to be updated when a change is made to this TTLSGroupAction statement. This enables the user to differentiate TTLSGroupAction statements, based on the instance identifier.

TTLSGroupAdvancedParms statement

Use the TTLSGroupAdvancedParms statement to specify advanced attributes for an AT-TLS group.

Syntax

Put Braces and Parameters on Separate Lines

TTLSGroupAdvancedParms Parameters

Parameters

name

A string 1 - 32 characters in length specifying the name of this TTLSGroupAdvancedParms statement.

Rule: If this TTLSGroupAdvancedParms statement is not specified inline within another statement, a *name* value must be provided. If a name value is not specified for an inline TTLSGroupAdvancedParms statement a nonpersistent system name is created.

SecondaryMap

Specifies whether the application establishes secondary connections that should use the secondary policy mapping method. Valid values are:

Off

A connection that maps to this policy should not be used as a primary connection in the secondary policy mapping method. This is the default.

On

A connection that maps to this policy should be used as a primary connection in the secondary policy mapping method. Future connections established between the same two IP addresses by the same process that do not map to any policy or map to a policy with a lower priority are considered secondary connections. These secondary connections use the same policy mapped by the associated primary connection.

SyslogFacility

Specifies which syslog facility name this group should use when writing messages to syslogd. The daemon facility is currently used by other TCP/IP stack functions. See [Chapter 15, “Syslog daemon,” on page 795](#) for more information about these functions. Specifying auth enables syslog messages written by this AT-TLS group to be easily separated from messages written by other AT-TLS groups or other applications running in the same TCP/IP address space by using the daemon facility. AT-TLS writes messages to syslogd by using the jobname of the TCP/IP started task. . Valid values are:

daemon

The daemon facility name is used. This is the default.

auth

The auth facility name is used.

Envfile

Specifies the name of a file that contains environment variables. The Language Environment process is initialized with the _CEE_ENVFILE environment variable set to this file. See [z/OS XL C/C++ Programming Guide](#) for more information about the _CEE_ENVFILE environment variable.

The *file* value is a z/OS UNIX path and file name, a fully qualified MVS data set, specified as //fully.qualified.name, or a DD statement defined to the TCP/IP stack, specified as DD:ddname, containing environment variables. The maximum length is 1 023 characters. MVS data sets should be defined with variable-length records.

Restriction: The GSK_TRACE environment variable should not be set using the Envfile parameter. Setting this variable could cause unpredictable results or abends when running applications using AT-TLS. If System SSL trace data is needed, see [z/OS Cryptographic Services System SSL Programming](#) for information about running the SSL started task to gather trace data.

TTLGskAdvancedParms statement

Use the TTLGskAdvancedParms statement to specify advanced attributes for an AT-TLS environment that are specific to System SSL.

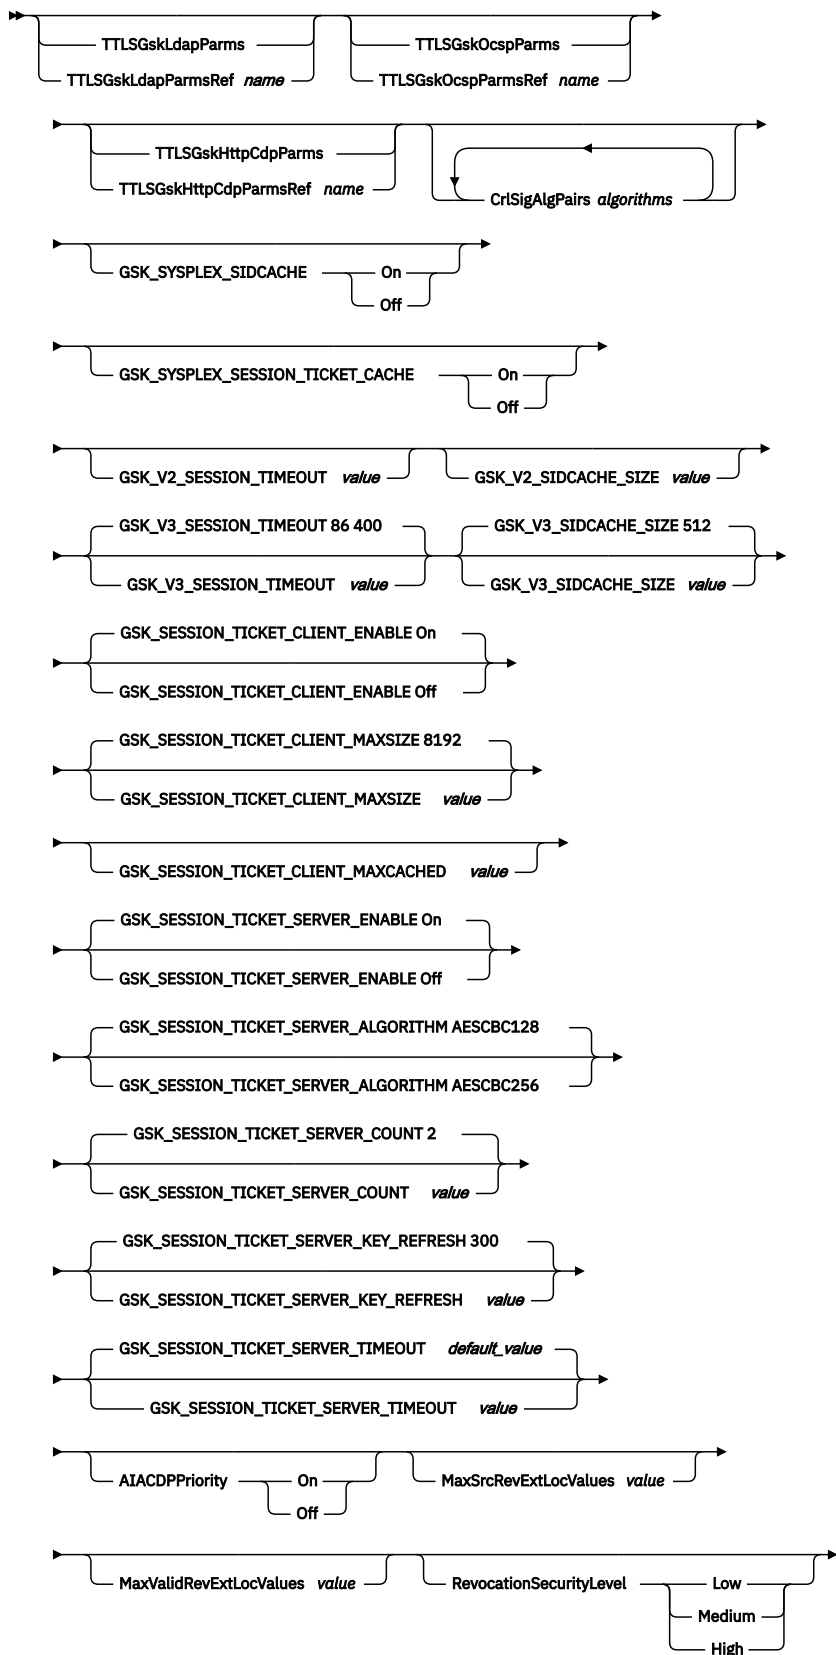

Syntax

Put Braces and Parameters on Separate Lines

TTLGskAdvancedParms Parameters

Parameters

name

A string 1 - 32 characters in length specifying the name of this `TTLSGskAdvancedParms` statement.

Rule: If this TTLSGskAdvancedParms statement is not specified inline within another statement, a *name* value must be provided. If a name is not specified for an inlineTTLSGskAdvancedParms statement, a nonpersistent system name is created.

TTLSGskLdapParms

An inline specification of a TTLSGskLdapParms statement.

TTLSGskLdapParmsRef

The name of a globally defined TTLSGskLdapParms statement.

TTLSGskOcspParms

An inline specification of a TTLSGskOcspParms statement.

TTLSGskOcspParmsRef

The name of a globally defined TTLSGskOcspParms statement.

TTLSGskHttpCdpParms

An inline specification of a TTLSGskHttpCdpParms statement.

TTLSGskHttpCdpParmsRef

The name of a globally defined TTLSGskHttpCdpParms statement.

CrlSigAlgPairs

CrlSigAlgPairs specifies a list of hash and signature algorithm pairs that are allowed for a Certificate Revocation List (CRL) retrieved from an LDAP or an HTTP server during revocation checking. CRL revocation checking through LDAP is enabled when the GSK_LDAP_SERVER parameter is specified on the TTLSGskLdapParms statement. CRL revocation checking through HTTP is enabled when the HttpCdpEnable parameter is set to On on the TTLSGskHttpCdpParms statement.

If a CrlSigAlgsPairs parameter is specified more than once, the values are concatenated to create a single list of hash and signature algorithm pairs. For System SSL, the GSK_CRL_SIGALG_PAIRS value is set to the concatenated value.

The *algorithms* value is a string of one or more 4-hexadecimal character signature algorithm pairs or a single signature algorithm pair constant. When using hexadecimal notation, the algorithm string cannot have intervening blanks between the hash and signature algorithm pairs. If duplicate hash and signature algorithm pairs are specified, the first instance is used, and all other instances are ignored. The maximum number of TLS hash and signature algorithm pairs is 64. There is no AT-TLS default. The signature algorithms pairs list can be specified as follows:

<i>Table 75. CrlSigAlgPairs SignaturePairs</i>	
Signature algorithm pair constant	Hexadecimal characters
TLS_SIGALG_MD5_WITH_RSA	0101
TLS_SIGALG_SHA1_WITH_RSA	0201
TLS_SIGALG_SHA1_WITH_DSA	0202
TLS_SIGALG_SHA1_WITH_ECDSA	0203
TLS_SIGALG_SHA224_WITH_RSA	0301
TLS_SIGALG_SHA224_WITH_DSA	0302
TLS_SIGALG_SHA224_WITH_ECDSA	0303
TLS_SIGALG_SHA256_WITH_RSA	0401
TLS_SIGALG_SHA256_WITH_DSA	0402
TLS_SIGALG_SHA256_WITH_ECDSA	0403
TLS_SIGALG_SHA384_WITH_RSA	0501
TLS_SIGALG_SHA384_WITH_ECDSA	0503
TLS_SIGALG_SHA512_WITH_RSA	0601

Table 75. CrlSigAlgPairs SignaturePairs (continued)	
Signature algorithm pair constant	Hexadecimal characters
TLS_SIGALG_SHA512_WITH_ECDSA	0603
TLS_SIGALG_SHA256_WITH_RSASSA_PSS	0804
TLS_SIGALG_SHA384_WITH_RSASSA_PSS	0805
TLS_SIGALG_SHA512_WITH_RSASSA_PSS	0806

Restriction: TLS_SIGALG_MD5_WITH_RSA (0x0101) cannot be specified when FIPS mode is enabled.

GSK_SYSPLEX_SESSION_TICKET_CACHE

Specifies whether sysplex TLS Version 1.3 session ticket caching is to be enabled for connections in this AT-TLS environment. Valid values are as follows:

On

Sysplex TLS Version 1.3 session ticket caching is to be enabled on the server. The session ticket information for each server issued ticket is stored in the sysplex session ticket cache.

Off

Sysplex TLSv1.3 session ticket caching is not to be enabled.

Restriction: The GSKSRVR must be started when sysplex session ticket caching is enabled. If sysplex session ticket caching is enabled and the GSKSRVR is not running, no session tickets will be sent from the server to the client. See [Configuring the SSL started task - IBM Documentation](#).

GSK_SYSPLEX_SIDCACHE

Specifies whether sysplex session identifier caching is to be enabled for connections in this AT-TLS environment. Valid values are as follows:

On

Sysplex session identifier caching is to be enabled. SSLv3, TLSv1.0, TLSv1.1, and TLSv1.2 protocol server session information can be stored in the sysplex session cache.

Off

Sysplex session identifier caching is not to be enabled.

Restriction: The GSKSRVR must be started when sysplex session identifier caching is enabled. If sysplex session identifier caching is enabled and the GSKSRVR is not running, session reuse will not occur between members of the sysplex. See [Configuring the SSL started task - IBM Documentation](#).

GSK_V2_SESSION_TIMEOUT

Specifies the SSL Version 2 session timeout. This is the number of seconds until a session identifier expires. Valid values are in the range 0 - 100.

GSK_V2_SIDCACHE_SIZE

Specifies the number of SSL Version 2 session identifiers to cache. Valid values are in the range 0 - 32 000.

GSK_V3_SESSION_TIMEOUT

Specifies the SSL Version 3, TLS Version 1.0, TLS Version 1.1, TLS Version 1.2, or TLS Version 1.3 session timeout. For SSL Version 3, TLS Version 1.0, TLS Version 1.1 and TLS Version 1.2, this value is the number of seconds that lapse until a session identifier expires. For TLS Version 1.3, this value is the number of seconds that lapse until a session ticket expires. Valid values are in the range 0 - 86 400. The default value is 86 400.

Result: If a value of 0 is specified, session identifiers and session tickets are not remembered.

GSK_V3_SIDCACHE_SIZE

Specifies the number of SSL Versions 3, TLS version 1.0, TLS version 1.1, TLS Version 1.2 session identifiers or TLS Version 1.3 session tickets to cache. The oldest entry will be removed when the cache is full to add a new entry.

Valid values are in the range 0 - 64 000. The cache is allocated by using the configured size rounded up to the power of 2, with a minimum of 16. The default value is 512.

For the SSL Version 3, TLS Version 1.0, TLS Version 1.1, and TLS Version 1.2 protocols, the cache is used to store session identifiers on the server and client sides. For the TLS Version 1.3 protocol, the cache is used to store session tickets on the client side, when GSK_SESSION_TICKET_CLIENT_ENABLE is On.

Result: If a value of 0 is specified, session identifiers and session tickets are not remembered.

GSK_SESSION_TICKET_CLIENT_ENABLE

Specifies if the client supports:

- caching session tickets received from a server after a TLS Version 1.3 handshake has completed
- TLS Version 1.3 session resumption attempts to the server

Valid values are:

On

Enables client caching of session tickets and session resumption attempts. On is the default.

Off

Disables client caching of session tickets and session resumption attempts.

Rule: The GSK_V3_SESSION_TIMEOUT and GSK_V3_SIDCACHE_SIZE settings must be set to values greater than 0 to allow client session ticket caching.

GSK_SESSION_TICKET_CLIENT_MAXCACHED

Specifies the maximum number of session tickets that are allowed to be cached by the client for each unique TLS Version 1.3 session. Valid values are in the range 1 – 128.

Rule: To allow client session ticket caching, GSK_SESSION_TICKET_CLIENT_ENABLE must be set ON and the GSK_V3_SESSION_TIMEOUT and GSK_V3_SIDCACHE_SIZE settings must be set to values greater than 0.

GSK_SESSION_TICKET_CLIENT_MAXSIZE

Specifies the maximum number of bytes of a session ticket that can be stored in the client session ticket cache. Session tickets sent by the server that exceed this size will be discarded by the client. Valid values are in the range 0 – 2 147 483 647. The default size is 8192 (8K).

Result: A value of 0 disables checking the session ticket size and allows a session ticket of any size.

Tip: Setting the session ticket size too small could implicitly disable the session ticket caching for the client.

GSK_SESSION_TICKET_SERVER_ENABLE

Specifies if the server supports:

- Sending session tickets after a TLS Version 1.3 handshake has completed
- Receiving TLS Version 1.3 session resumption attempts from the client

Valid values are:

On

Enables TLS Version 1.3 server session resumption. On is the default.

Off

Disables TLS Version 1.3 server session resumption attempts.

GSK_SESSION_TICKET_SERVER_ALGORITHM

Specifies the algorithm to be used by the server to encrypt and decrypt the session tickets used for TLS Version 1.3 session resumption.

Valid values are AESCBC128 and AESCBC256. The default is AESCBC128.

Restriction: If sysplex session ticket caching is enabled (GSK_SYSPLEX_SESSION_TICKET_CACHE is set ON), this parameter is not used.

GSK_SESSION_TICKET_SERVER_COUNT

Specifies the number of TLS Version 1.3 session tickets that is sent by the server to the client after the initial handshake completes. Each session ticket provides the client with the means to request the resumption of a TLS Version 1.3 session. If the value is greater than 0, each subsequent resumed session sends a single session ticket to replace the one used for resumption. Valid values are in the range 0 - 16. The default value is 2.

GSK_SESSION_TICKET_SERVER_KEY_REFRESH

Specifies the key refresh interval, in seconds, of the encryption key used by the server to encrypt session tickets for TLS Version 1.3 session resumption. When the encryption key is refreshed, a new primary encryption key is generated, and the former encryption key is retained as a secondary key that can be used only for decryption until a subsequent refresh occurs.

Valid values are in the range 0 – 604 800 (7 days). The default value is 300 (5 minutes).

Result: If a value of 0 is specified, the encryption key never refreshes.

Restriction: If sysplex session ticket caching is enabled (GSK_SYSPLEX_SESSION_TICKET_CACHE is set ON), this parameter is not used.

GSK_SESSION_TICKET_SERVER_TIMEOUT

Specifies the maximum time, in seconds, that a server will accept a TLS Version 1.3 session resumption request from the client measured in seconds from the initial handshake. The server will continue to generate a new session ticket for each new resumed handshake until the timeout has been reached. Each session ticket generated by the server will be valid until the timeout has been reached.

If sysplex session ticket caching is not enabled (GSK_SYSPLEX_SESSION_TICKET_CACHE is set to OFF), the key used to encrypt the session ticket must be available when the client attempts resumption. In this configuration, the GSK_SESSION_TICKET_SERVER_KEY_REFRESH value will impact the lifetime of a session ticket.

Valid values are in the range 1 – 604 800 (7 days).

default_value

If sysplex session ticket caching is not enabled (GSK_SYSPLEX_SESSION_TICKET_CACHE is set to OFF), the default value is 300 (5 minutes).

If sysplex session ticket caching is enabled (GSK_SYSPLEX_SESSION_TICKET_CACHE is set to ON), the default session ticket timeout value is 600 (10 minutes).

AIACDPriority

Specifies the priority order that the AIA and CRL Distribution Point (CDP) extensions, in the certificate, are checked for revocation information.

Valid values are as follows:

On

The AIA extension is processed before the CDP extension during certificate revocation checking. Any OCSP responders specified in the AIA extension or in OcsplUrl are contacted before any attempt is made to contact the HTTP servers specified in the HTTP URL values in the CDP extension.

Off

The CDP extension is queried before the AIA extension. The HTTP servers specified in the HTTP URL values in the CDP extension are contacted before any attempt is made to contact the OCSP responders specified in the AIA extension or in OcsplUrl.

This parameter sets System SSL's GSK_AIA_CDP_PRIORITY attribute.

Tips:

- The HttpCdpEnable parameter must be set to On on the TTLSGskHttpCdpParms statement to enable searching HTTP URL values in the certificate's CDP extension.

- If GSK_LDAP_SERVER is specified on the TTLSGskLdapParms statement, certificate revocation checking by using LDAP is available as a fallback. GSK_LDAP_SERVER is checked last for certificate revocation information.

MaxSrcRevExtLocValues

Sets the maximum number of location values that are contacted per HTTP CDP or AIA extension when an attempt is made to validate a certificate. Valid location values are in the range 0 - 256. A value of 0 indicates that no limit is set on the number of locations contacted. This parameter sets System SSL's GSK_MAX_SOURCE_REV_EXT_LOC_VALUES attribute.

Result: The locations for revocation information are specified by accessLocation in the AIA certificate extension for OCSP and by distributionPoint in the CDP extension for HTTP CRLs. When locations are available in an AIA or CDP extension, certificate validation processing attempts to contact the OCSP or HTTP server. Both AIA and CDP extensions can contain multiple location values. A large number of locations can impact performance.

MaxValidRevExtLocValues

Sets the maximum number of location values that are contacted when validation of a certificate is performed. Valid location values are in the range 0 - 1024. A value of 0 indicates that no limit is set on the number of locations contacted. This parameter sets System SSL's GSK_MAX_VALIDATION_REV_EXT_LOC_VALUES attribute.

Result: The locations for revocation information are specified by accessLocation in the AIA certificate extension for OCSP and by distributionPoint in the CDP extension for HTTP CRLs. When locations are available in an AIA or CDP extension, certificate validation processing attempts to contact the OCSP or HTTP server. Both AIA and CDP extensions can contain multiple location values. A large number of locations can impact performance.

RevocationSecurityLevel

Specifies the level of security to use when an OCSP responder or an HTTP server specified in an HTTP URL value in the CDP extension is contacted.

This parameter sets System SSL's GSK_REVOCATION_SECURITY_LEVEL attribute.

The following levels of security are available:

Low

Certificate validation does not fail if the OCSP responder or HTTP server specified in the HTTP URL value in the CDP extension cannot be contacted.

Medium

Certificate validation requires the OCSP responder or the HTTP server in an HTTP URL value in the CDP extension to be able to be contacted. For an OCSP responder, it must be able to provide a valid certificate revocation status. If the certificate status is revoked or unknown, certificate validation fails. For an HTTP server in the CDP extension, it must be able to be contacted and provide a CRL.

High

Certificate validation requires revocation information to be provided by the OCSP responder or HTTP server. If OCSP revocation checking by using the AIA extension is enabled, the OCSP responder specified in the certificate must be able to be contacted and provide valid certificate revocation status. If HTTP CRL checking is enabled, the HTTP server specified in the HTTP URL values in the CDP extension must be able to be contacted and provide a CRL.

Tips:

- When revocation information is not found in cache, an attempt to contact an OCSP responder or an HTTP server is performed. To enforce contact with the OCSP responder or the HTTP server for each validation, caching must be disabled.
- If GSK_LDAP_SERVER is specified, it is checked last for certificate revocation information if OCSP or HTTP CDP is enabled. If the OCSP responders or the HTTP servers cannot be contacted, you can enable fallback to an LDAP server by setting the RevocationSecurityLevel parameter to Low. This enables contact to the LDAP server specified in the GSK_LDAP_SERVER parameter.

TTLGskHttpCdpParms statement

Use the TTLGskHttpCdpParms statement to define a set of HTTP parameters that are used for Certificate Revocation List (CRL) checking for an AT-TLS environment action. A TTLGskHttpCdpParms statement can be specified inline in a TTLGskAdvancedParms statement or referenced by a TTLGskAdvancedParms statement.

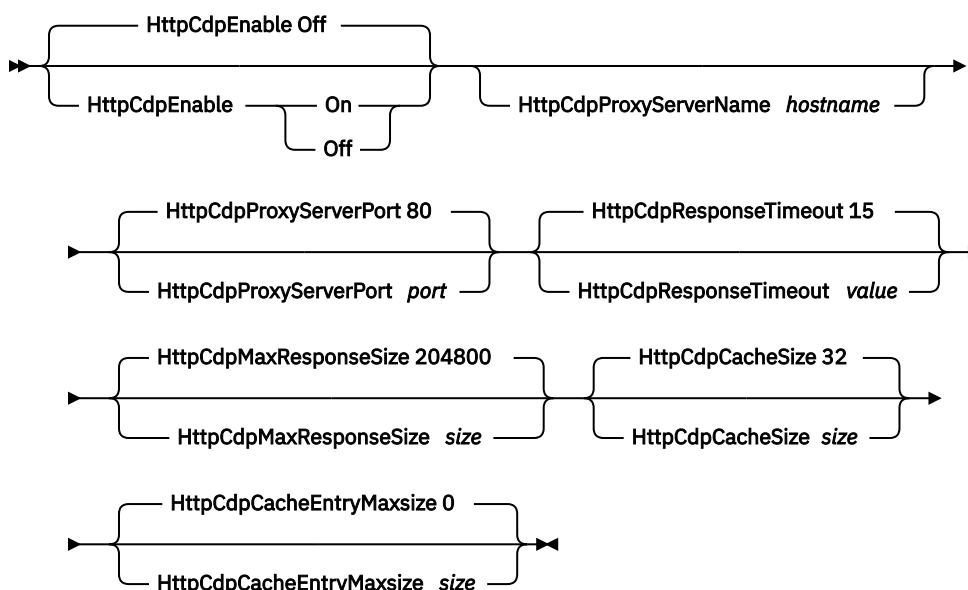

Syntax

Put Braces and Parameters on Separate Lines

TTLGskHttpCdpParms Parameters

Parameters

name

A string of 1 - 32 characters in length that specifies the name of this TTLGskHttpCdpParms statement.

HttpCdpEnable

Specifies that the HTTP URIs within the certificate's CDP extension are used for certificate revocation checking. The values are On and Off. Off is the default value.

This parameter sets System SSL's GSK_HTTP_CDP_ENABLE attribute.

HttpCdpProxyServerName

Specifies the DNS name or IP address of the HTTP proxy server for HTTP CDP CRL retrieval. When DNS name is used, the maximum length is 255 characters.

This parameter sets System SSL's GSK_HTTP_CDP_PROXY_SERVER_NAME attribute.

HttpCdpProxyServerPort

Sets the HTTP proxy server port for HTTP CDP CRL retrieval. Valid values are in the range 1- 65535. Port 80 is used by default if no HTTP proxy server port is set.

This parameter sets System SSL's GSK_HTTP_CDP_PROXY_SERVER_PORT attribute.

HttpCdpResponseTimeout

Sets the time in seconds to wait for a complete response from the HTTP server. The default value is 15. A value of 0 indicates that no time limit is set for HTTP CRL retrieval. The maximum time that can be set is 43200 seconds.

This parameter sets System SSL's GSK_HTTP_CDP_RESPONSE_TIMEOUT attribute.

HttpCdpMaxResponseSize

Sets the maximum size in bytes of a response that is accepted from an HTTP server when retrieving a CRL. A value of 0 indicates that size checking is disabled and that a CRL of any size is allowed. If the value for the maximum response size is too small, HTTP CRL support is implicitly disabled. The default value is 204800 (200 KB). The maximum size that can be set is 2147483647 bytes.

This parameter sets System SSL's GSK_HTTP_CDP_MAX_RESPONSE_SIZE attribute.

HttpCdpCacheSize

Sets the maximum number of CRLs that are allowed to be stored in the HTTP CDP CRL cache. The default value is 32. A value of 0 indicates that HTTP CDP CRL caching is not active and the HTTP server is contacted for each validation. The maximum number of CRLs that are allowed to be stored in the HTTP CDP CRL cache cannot exceed 32000.

This parameter sets System SSL's GSK_HTTP_CDP_CACHE_SIZE attribute.

Tip: CRLs are cached only when they contain a nextUpdate time. If a CRL does not contain a nextUpdate time, the CRL is valid only at the time that the CRL was provided.

HttpCdpCacheEntryMaxsize

Sets the maximum CRL size in bytes that is allowed to be stored in the HTTP CDP CRL cache. If a CRL is larger than the specified maximum size, it is not cached. The default value is 0, which indicates that no limit is set to the size of the CRL that is stored in the HTTP CDP CRL cache. The maximum CRL size that is allowed to be stored in the HTTP CDP CRL cache cannot exceed 2147483647 bytes.

This parameter sets System SSL's GSK_HTTP_CDP_CACHE_ENTRY_MAXSIZE attribute.

TTLGskLdapParms statement

Use the TTLGskLdapParms statement to define a set of LDAP parameters to be used for Certificate Revocation List (CRL) checking for an AT-TLS environment action. A TTLGskLdapParms statement can be specified inline in a TTLSEnvironmentAction statement or referenced by an TTLSEnvironmentAction statement.

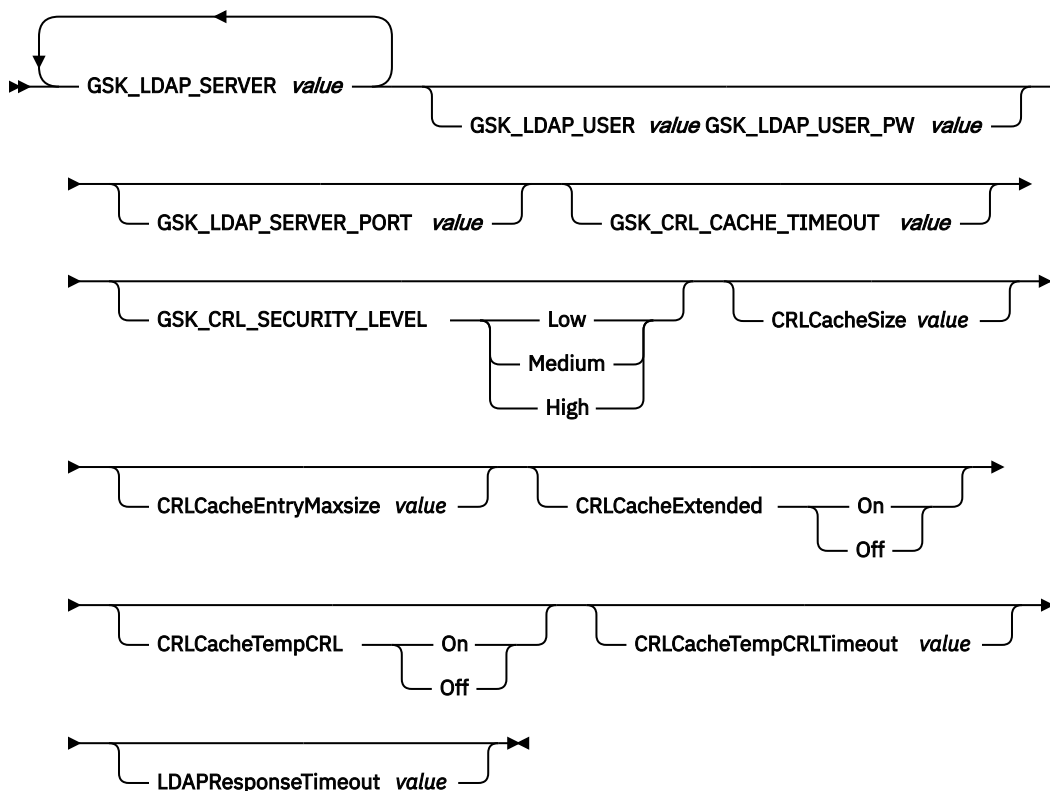

Syntax

Put Braces and Parameters on Separate Lines

TTLGskLdapParms Parameters

Parameters

name

A string 1 - 32 characters in length specifying the name of this TTLSGskLdapParms statement.

Rule: If this TTLSGskLdapParms statement is not specified inline within another statement, a *name* value must be provided. If a name is not specified for an inlineTTLSGskLdapParms statement, a nonpersistent system name is created.

GSK_LDAP_SERVER

Specifies an LDAP server host name. The name can contain an optional port number that is separated from the name by a colon. The name can be a DNS resource name, a dotted-decimal IPv4 address or a colon-separated IPv6 address that is enclosed in square brackets (for example, [1080::8:800:200C:417A]). The maximum length of the host name is 255 characters. Valid values for the port number, if specified, are 1 - 65535. Up to five GSK_LDAP_SERVER statements can be defined.

GSK_LDAP_USER

Specifies the distinguished name to use when connecting to the LDAP server. The maximum length of the name is 512 characters.

Rule: Comment indicators and embedded blanks are treated as part of the value for this attribute. For example:

```
GSK_LDAP_USER  cn=cert #label
value used:    cn=cert #label
```

Restriction: When the value contains embedded blanks, you must specify the entire value within the first 1536 characters of the configuration file line.

GSK_LDAP_USER_PW

Specifies the password to use when connecting to the LDAP server. The maximum length of the password is 512 characters.

GSK_LDAP_SERVER_PORT

Specifies the LDAP server port. This port is used if a port is not specified on the LDAP server host name. Valid values are in the range 1 - 65535.

GSK_CRL_CACHE_TIMEOUT

Sets the CRL cache timeout in hours. Valid values are in the range 0 - 720.

GSK_CRL_SECURITY_LEVEL

Specifies the level of security to use when an LDAP server is contacted. Valid values are as follows:

Low

Specifies that certificate validation does not fail if the LDAP server cannot be contacted.

Medium

Specifies that certificate validation requires the LDAP server to be able to be contacted, but it does not require a CRL to be defined.

High

Specifies that certificate validation requires the LDAP server to be able to be contacted, and a CRL must be defined.

Tips:

- If LDAP basic CRL cache support is enabled and CRLCacheExtended is set to Off, CRLs located are cached according to the GSK_CRL_CACHE_TIMEOUT setting. If a CRL is in the cache for a certificate, System SSL will not try to retrieve a CRL until the GSK_CRL_CACHE_TIMEOUT value is reached. To contact the LDAP server every time a certificate is being validated, set GSK_CRL_CACHE_TIMEOUT to 0 to disable CRL caching.
- If LDAP extended CRL cache support is enabled, CRLs located are cached only if CRLs contain a nextUpdate value that is greater than the value of the current time. If you want System SSL to contact the LDAP server every time a certificate is being validated then set CRLCacheSize to 0 to disable CRL caching. If a CRL is not defined and GSK_CRL_CACHE_TEMP_CRL is set to On, System SSL will not attempt to retrieve the CRL until the CRLCacheTempCRLTimeout value is reached.

CRLCacheSize

Sets the maximum number of CRLs that are allowed to be stored in the LDAP CRL cache. A value of 0 indicates that LDAP CRL caching is not enabled. The number of CRLs that are allowed to be stored in the LDAP CRL cache cannot exceed 32000.

This parameter sets System SSL's GSK_CRL_CACHE_SIZE attribute.

CRLCacheEntryMaxsize

Sets the maximum CRL size in bytes that is allowed to be stored in the LDAP CRL cache. If a CRL is larger than the specified maximum size, it is not cached. Valid values are in the range 0 - 2147483647 bytes. The default value set by System SSL is 0, which means that the size of the CRL that is stored in the LDAP CRL cache is unlimited.

This parameter sets System SSL's GSK_CRL_CACHE_ENTRY_MAXSIZE attribute.

CRLCacheExtended

Specifies that LDAP extended CRL cache support is enabled. The following values are valid:

On

Indicates that LDAP extended CRL cache support is enabled.

Tip: When CRLCacheExtended is set to On, the following support is enabled:

- LDAP CRLs are cached only when they contain an expiration time that is later than the current time. The nextUpdate value specifies the expiration time.
- The default value set by System SSL for the maximum number of CRLs that can be stored in the LDAP cache is 32. This number can be overridden by specifying CRLCacheSize.
- The GSK_CRL_CACHE_TIMEOUT value is ignored. If CRLCacheExtended is set to On, the following WARNING message is issued:

GSK_CRL_CACHE_TIMEOUT will be ignored because CRLCacheExtended is configure with a value of On.

Off

Indicates that LDAP basic CRL cache support is enabled.

Tip: When CRLCacheExtended is set to Off, the following support is enabled:

- Retrieved LDAP CRLs are cached only if GSK_CRL_CACHE_TIMEOUT is greater than 0 and CRLCacheSize is set to a nonzero value.
- CRLs stay in the cache for a maximum of 24 hours by default. Every 24 hours after the first CRL is added to the cache, the entire cache is emptied. You can specify GSK_CRL_CACHE_TIMEOUT to change the number of hours that the CRLs stay in the cache.
- If the LDAP server does not contain the CRL, temporary CRLs are placed into the cache by default. You can set CRLCacheTempCRL to Off to disable temporary CRL caching.

This parameter sets System SSL's GSK_CRL_CACHE_EXTENDED attribute.

CRLCacheTempCRL

Specifies whether a temporary LDAP CRL cache entry is added to the LDAP CRL cache when the CRL does not reside on the LDAP server.

On

Indicates that a temporary CRL cache entry is to be added to the LDAP CRL cache.

Off

Indicates that a temporary CRL cache entry is not to be added to the LDAP CRL cache.

This parameter sets System SSL's GSK_CRL_CACHE_TEMP_CRL attribute.

Tip: If a temporary CRL is cached, it prevents continual attempts to contact the LDAP server and allows connections to be successful.

CRLCacheTempCRLTimeout

Sets the time in hours that a temporary CRL cache entry resides in the LDAP CRL cache. A temporary LDAP CRL cache entry is added to the LDAP CRL cache when the CRL does not reside on the LDAP server. Valid values are in the range 1 - 720 hours. The default value is 24 hours.

This parameter sets System SSL's GSK_CRL_CACHE_TEMP_CRL_TIMEOUT attribute.

Tip: This support is available only when both CRLCacheExtended and CRLCacheTempCRL are set to On. If CRLCacheTempCRLTimeout is set to a value greater than 0 and either CRLCacheExtended is set to Off or CRLCacheTempCRL is set to Off, the following warning message is issued:

CRLCacheTempCRLTimeout is only available when CRLCacheExtended is set to On and CRLCacheTempCRL is set to On.

LDAPResponseTimeout

Sets the time in seconds to wait for a response from the LDAP server. Valid values are in the range 0 - 43200 seconds. A value of 0 indicates that no time limit is set for LDAP CRL retrievals.

This parameter sets System SSL's GSK_LDAP_RESPONSE_TIMEOUT attribute.

TTLSGskOcspParms statement

Use the TTLSGskOcspParms statement to define a set of OCSP parameters to use for Certificate Revocation List (CRL) checking for an AT-TLS environment action. A TTLSGskOcspParms statement can be specified inline in a TTLSGskAdvancedParms statement or referenced by a TTLSGskAdvancedParms statement.

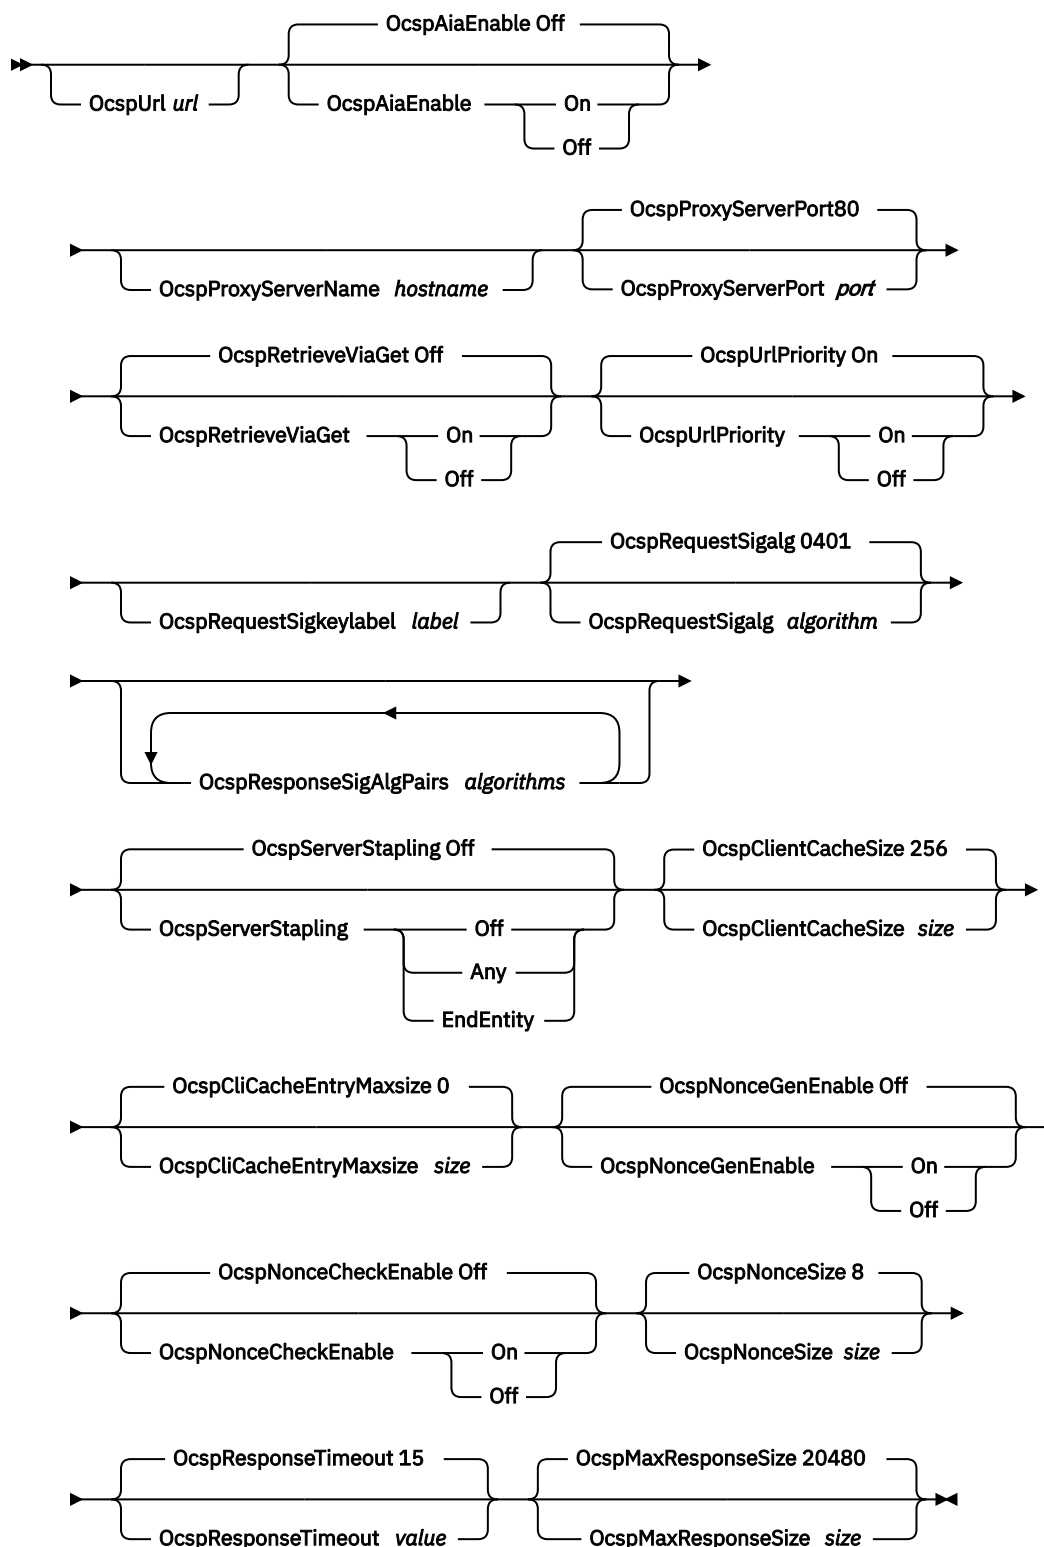

Syntax

Put Braces and Parameters on Separate Lines

TLSGskOcspParms Parameters

Parameters

OcspUrl

Specifies the HTTP URL of an OCSP responder. The OCSP responder is used to obtain certificate revocation status during certificate validation. A certificate does not need an AIA extension if a responder URL is configured by using this option.

The value must conform to the definition of an HTTP URL:

```
http_URL = "http:" "://" host [ ":" port ] [ abs_path [ "?" query ] ]
```

where *host* can be an IPv4 or IPv6 IP address, or a domain name. The maximum length of the *OcspUrl* is 2083 characters.

Tips:

- If *OcspUrl* is specified, *OcspAiaEnable* is set to On and *OcspUrlPriority* is set to On, the responder defined by *OcspUrl* is used before the responders identified in the AIA extension are used.
- If *OcspUrl* is specified, *OcspAiaEnable* is set to On and *OcspUrlPriority* is set to Off, the responders identified in the AIA extension are used before the responder defined by *OcspUrl* is used.

This parameter sets System SSL's GSK_OCSP_URL attribute.

OcspAiaEnable

Specifies whether the AIA extensions in the certificate are used for revocation checking.

On

Indicates that the AIA extension in the certificate is used for certificate revocation checking.

Off

Indicates that the AIA extension in the certificate is not used for certificate revocation checking. This is the default.

Tips:

- Use this parameter to set the SSL attribute GSK_OCSP_ENABLE.
- If *OcspUrl* is specified, *OcspAiaEnable* is set to On and *OcspUrlPriority* is set to On, the responder defined by *OcspUrl* is used before the responders identified in the AIA extension are used.
- If *OcspUrl* is specified, *OcspAiaEnable* is set to On and *OcspUrlPriority* is set to Off, the responders identified in the AIA extension are used before the responder defined by *OcspUrl* is used.

OcspProxyServerName

Specifies the DNS name or IP address of the OCSP proxy server. When DNS name is used, the maximum length is 255 characters.

This parameter sets System SSL's GSK_OCSP_PROXY_SERVER_NAME attribute.

OcspProxyServerPort

Sets the OCSP responder port for the proxy server. The port must be in the range 1 - 65535. Port 80 is used if no OCSP proxy server port is set.

This parameter sets System SSL's GSK_OCSP_PROXY_SERVER_PORT attribute.

OcspRetrieveViaGet

Specifies whether the HTTP request to the OCSP responder is sent by using either the HTTP Get Method or the HTTP Post Method. Valid values are as follows:

On

Indicates that the HTTP GET Method is used when sending an OCSP request whose total request size, after Base64 encoding, is less than 255 bytes. Use this option to enable HTTP caching on the OCSP responder when the responder is enabled for caching.

Off

Indicates that the HTTP request is sent by using an HTTP Post Method. This is the default.

This parameter sets System SSL's GSK_OCSP_RETRIEVE_VIA_GET attribute.

OcspUrlPriority

Specifies the order of precedence for contacting OCSP responder locations if both *OcspUrl* and *OcsAiaEnable* are active.

On

Indicates that the responder defined by *OcspUrl* is used before the responders identified in the AIA extension are used. This is the default.

Off

Indicates that the responders identified in the AIA extension are used before the responder defined by OcspUrl is used.

This parameter sets System SSL's GSK_OCSP_URL_PRIORITY attribute.

OcspRequestSigkeylabel

Specifies the label of the key to use to sign OCSP requests. OCSP requests are signed only when a key label is specified. The maximum length of the OcspRequestSigkeylabel is 127 characters.

Only requests that are sent to the OCSP responder identified by using the OcspUrl setting are signed. Requests that are sent to an OCSP responder selected from a certificate AIA extension are not signed.

This parameter sets System SSL's GSK_OCSP_REQUEST_SIGKEYLABEL attribute.

OcspRequestSigalg

Specifies the hash and signature algorithm pair to use to sign OCSP requests as a string that consists of a 4-character value. The default value is RSA with SHA256 ('0401').

Only requests that are sent to the OCSP responder identified by using the OcspUrl setting are signed.

This parameter sets System SSL's GSK_OCSP_REQUEST_SIGALG attribute. See the following table for the supported signature algorithm pair constants that can be specified.

<i>Table 76. OcspRequestSigalg SignaturePairs</i>	
Signature algorithm pair constant	Hexadecimal characters
TLS_SIGALG_MD5_WITH_RSA	0101
TLS_SIGALG_SHA1_WITH_RSA	0201
TLS_SIGALG_SHA1_WITH_DSA	0202
TLS_SIGALG_SHA1_WITH_ECDSA	0203
TLS_SIGALG_SHA224_WITH_RSA	0301
TLS_SIGALG_SHA224_WITH_DSA	0302
TLS_SIGALG_SHA224_WITH_ECDSA	0303
TLS_SIGALG_SHA256_WITH_RSA	0401
TLS_SIGALG_SHA256_WITH_DSA	0402
TLS_SIGALG_SHA256_WITH_ECDSA	0403
TLS_SIGALG_SHA384_WITH_RSA	0501
TLS_SIGALG_SHA384_WITH_ECDSA	0503
TLS_SIGALG_SHA512_WITH_RSA	0601
TLS_SIGALG_SHA512_WITH_ECDSA	0603
TLS_SIGALG_SHA256_WITH_RSASSA_PSS	0804
TLS_SIGALG_SHA384_WITH_RSASSA_PSS	0805
TLS_SIGALG_SHA512_WITH_RSASSA_PSS	0806

Restriction: TLS_SIGALG_MD5_WITH_RSA (0x0101) cannot be specified when FIPS mode is enabled.

OcspResponseSigAlgPairs

Specifies a preference ordered list of signature algorithm pairs to be sent on the OCSP request that may be used by the OCSP responder to select an appropriate algorithm for signing the OCSP response. The OCSP response will be rejected if OcspResponseSigAlgPairs is specified and the OCSP

response is signed by a signature algorithm that was not specified in the list. The algorithms value is a string of one or more 4-hexadecimal character signature algorithm pairs or a single signature algorithm pair constant in order of preference. When using hexadecimal notation, the algorithm string cannot have intervening blanks between the signature algorithm pairs. If duplicate signature algorithm pairs are specified, the first instance is used and all other instances are ignored. The maximum number of TLS signature algorithm pairs is 64. The default value is null. The System SSL environment variable associated with this parameter is GSK_OCSP_RESPONSE_SIGALG_PAIRS. The signature algorithms pairs list can be specified as follows:

<i>Table 77. OcspResponseSigAlgPairs SignaturePairs</i>	
Signature algorithm pair constant	Hexadecimal characters
TLS_SIGALG_MD5_WITH_RSA	0101
TLS_SIGALG_SHA1_WITH_RSA	0201
TLS_SIGALG_SHA1_WITH_DSA	0202
TLS_SIGALG_SHA1_WITH_ECDSA	0203
TLS_SIGALG_SHA224_WITH_RSA	0301
TLS_SIGALG_SHA224_WITH_DSA	0302
TLS_SIGALG_SHA224_WITH_ECDSA	0303
TLS_SIGALG_SHA256_WITH_RSA	0401
TLS_SIGALG_SHA256_WITH_DSA	0402
TLS_SIGALG_SHA256_WITH_ECDSA	0403
TLS_SIGALG_SHA384_WITH_RSA	0501
TLS_SIGALG_SHA384_WITH_ECDSA	0503
TLS_SIGALG_SHA512_WITH_RSA	0601
TLS_SIGALG_SHA512_WITH_ECDSA	0603
TLS_SIGALG_SHA256_WITH_RSASSA_PSS	0804
TLS_SIGALG_SHA384_WITH_RSASSA_PSS	0805
TLS_SIGALG_SHA512_WITH_RSASSA_PSS	0806

Restriction: TLS_SIGALG_MD5_WITH_RSA (0x0101) cannot be specified when FIPS mode is enabled.

OcspServerStapling

Specifies TLS server support for the inclusion of the OCSP response for the server's end entity certificate or certificate chain as a TLS extension during the TLS handshake when requested by the TLS client. For System SSL, GSK_SERVER_OCSP_STAPLING is set to this value. Valid values are:

Off

Disables the server from contacting OCSP responders to retrieve the OCSP responses for the server's end entity certificate or the server's certificate chain. This is the default.

Any

Enables the server to contact the OCSP responders to retrieve the OCSP responses for the server's end entity certificate and the server's certificate chain, if requested by a TLSv1.2 or earlier client.

Result: If the negotiated handshake protocol is TLSv1.3 and greater, the retrieval of the OCSP responses for the server's certificate chain is not supported. A value of Any enables the server to contact the OCSP responders to retrieve the OCSP responses for the server's end entity certificate only.

EndEntity

Enables the server to contact the OCSP responders to retrieve the OCSP response for the server's end entity certificate only.

Restriction: If 'Any' or 'EndEntity' is specified, then either OcspUrl or OcspAiaEnable On must also be specified.

OcspClientCacheSize

Sets the maximum number of OCSP responses or cached certificate statuses to be kept in the OCSP response cache. The valid cache size number is in the range 0 - 32000. The default number is 256. If 0 is specified, the OCSP response cache is disabled. The OCSP response cache is allocated by using the requested size rounded up to the nearest multiple of 16 with a minimum size of 16.

This parameter sets System SSL's GSK_OCSP_CLIENT_CACHE_SIZE attribute.

OcspCliCacheEntryMaxsize

Sets the maximum number of OCSP responses or cached certificate statuses that are allowed to be kept in the OCSP response cache for an issuing CA certificate. The number is in the range 0 - 32000 and must be less than or equal to the size specified for OcspClientCacheSize. The size is set to 0 by default, which means that no limit is set on the number of cached certificate statuses allowed for a specific issuing CA certificate other than the limit imposed by OcspClientCacheSize.

Tip: Use OcspClientCacheSize to specify the total number of cached certificate statuses allowed in the entire OCSP cache. If this count is exceeded, any expired certificate statuses are first removed. If no expired certificate statuses have the same issuing CA certificate, the certificate status that is closest to the expiration time is removed first. If OcspCliCacheEntryMaxsize is set to a value greater than OcspClientCacheSize, the following warning message is issued:

OcspCliCacheEntryMaxsize must be less than or equal to the size specified for OcspClientCacheSize.

This parameter sets System SSL's GSK_OCSP_CLIENT_CACHE_ENTRY_MAXSIZE attribute.

OcspNonceGenEnable

Specifies whether the OCSP request includes a generated nonce.

On

Indicates that OCSP nonce generation is enabled.

Off

Indicates that OCSP nonce generation is disabled. This is the default.

This parameter sets System SSL's GSK_OCSP_NONCE_GENERATION_ENABLE attribute.

OcspNonceCheckEnable

Specifies whether checking of the nonce in the OCSP response is enabled.

On

Indicates that the nonce in the OCSP response is checked to ensure that it matches the one that is sent in the OCSP request.

Off

Indicates that the checking of the nonce in the OCSP response is disabled. This is the default.

Tips:

- If OcspNonceCheckEnable is set to On, OcspNonceGenEnable is implicitly set to On. If OcspNonceGenEnable is set to Off, the following warning message is issued and the OcspNonceGenEnable is set to On:

OcspNonceGenEnable is being set to a value of On because OcspNonceCheckEnable was configured with a value of Off.

- You can set OcspNonceCheckEnable to On to improve security. However, if the OCSP responder does not support nonces, it might cause failures.

This parameter sets System SSL's GSK_OCSP_NONCE_CHECK_ENABLE attribute.

OcspNonceSize

Specifies the nonce size in bytes to be sent in OCSF requests. Valid values are in the range 8 - 256 bytes.

The minimum and default size are 8 bytes.

This parameter sets System SSL's GSK_OCSP_NONCE_SIZE attribute.

OcspResponseTimeout

Specifies the time in seconds to wait for a complete response from the OCSF responder. Valid values are in the range 0 - 43200 seconds. A value of 0 indicates that no time limit is set. The default value is 15 seconds.

This parameter sets System SSL's GSK_OCSP_RESPONSE_TIMEOUT attribute.

OcspMaxResponseSize

Specifies the maximum size in bytes allowed in a response from an OCSF responder. A value of 0 disables checking the size and allows an OCSF response of any size. If the value for the maximum response size is too small, OCSF support is implicitly disabled. Valid values are in the range 0 - 2147483647. The default value is 20480 (20 KB).

This parameter sets System SSL's GSK_OCSP_MAX_RESPONSE_SIZE attribute.

TTLSTKeyringParms statement

Use the TTLSTKeyringParms statement to define a set of key ring parameters for an AT-TLS environment action. A TTLSTKeyringParms statement can be specified inline in a TTLSEnvironmentAction statement or referenced by a TTLSEnvironmentAction statement.

Syntax

Put Braces and Parameters on Separate Lines

TTLSTKeyringParms Parameters

Parameters

name

A string 1 - 32 characters in length specifying the name of this TTLSTKeyringParms statement.

Rule: If this TTLSTKeyringParms statement is not specified inline within another statement, a *name* value must be provided. If a name is not specified for an inline TTLSTKeyringParms statement, a nonpersistent system name is created.

To specify a SAF key ring use the Keyring parameter.

Keyring

Specifies the name of the SAF key ring in the format *userID/keyring*. The *userID* is the z/OS user ID that owns the keyring. If *userID* is not specified, then AT-TLS will use the z/OS *userID* that invoked the sockets API call that caused AT-TLS to process the TLS handshake. For System SSL, the GSK_KEYRING_FILE value is set to the value specified. Valid values are 1 - 1 023 characters in length.

Tips:

- If the owner of the keyring is always the same, then the *userID* should be coded on the Keyring parameter.
- If connections belonging to different user IDs will be protected by an AT-TLS rule using the Keyring parameter, the *userID* should be omitted from the Keyring parameter and each affected user must have their own keyring with the specified name.

To specify a z/OS PKCS #11 token name use the Keyring parameter.

Keyring

Specifies the path name of the z/OS PKCS #11 token as *TOKEN*/token-name. *TOKEN* indicates that the specified key ring is actually a token name. The token-name is limited to 32 characters in length. See [z/OS Cryptographic Services ICSF Writing PKCS #11 Applications](#) for more information on PKCS #11 tokens. For System SSL, the GSK_KEYRING_FILE value is set to the value specified.

To specify a z/OS UNIX key database use the Keyring parameter, along with either the KeyringPw or KeyringStashFile parameter.

Keyring

Specifies the path and file name of the key database z/OS UNIX file. A KeyringPw or KeyringStashFile must also be specified. For System SSL, the GSK_KEYRING_FILE value is set to the value specified. Valid values are 1 - 1 023 characters in length.

KeyringPw

Specifies the password for the key database. For System SSL, GSK_KEYRING_PW is set to this value. Valid values are in the range 1 - 128 characters in length.

KeyringStashFile

Specifies the path and file name of the key database password stash file. For System SSL, GSK_KEYRING_STASH_FILE is set to this value. Valid values are in the range 1 - 1 023 characters in length.

If both a KeyringPw value and a KeyringStashFile value are specified, System SSL will use the KeyringPw value.

TTLRule statement

Use the TTLRule statement to define an AT-TLS rule.

The FLUSH/NOFLUSH and PURGE/NOPURGE parameters can be used to specify whether or not AT-TLS policies are deleted at startup (and when a MODIFY REFRESH command is entered) and shutdown, respectively.

The information provided on the TTLRule statement defines an AT-TLS rule. The AT-TLS rule must have at least one local IP address, remote IP address, local port, remote port, job name, or user ID specification. The AT-TLS rule must have a direction specification and a TTLGroupActionRef parameter. The AT-TLS rule can contain a priority, a TTLConnectionActionRef parameter, a TTLEnvironmentActionRef parameter and an IpTimeCondition specification. An IpTimeCondition specification identifies a time period when the AT-TLS rule is in effect.

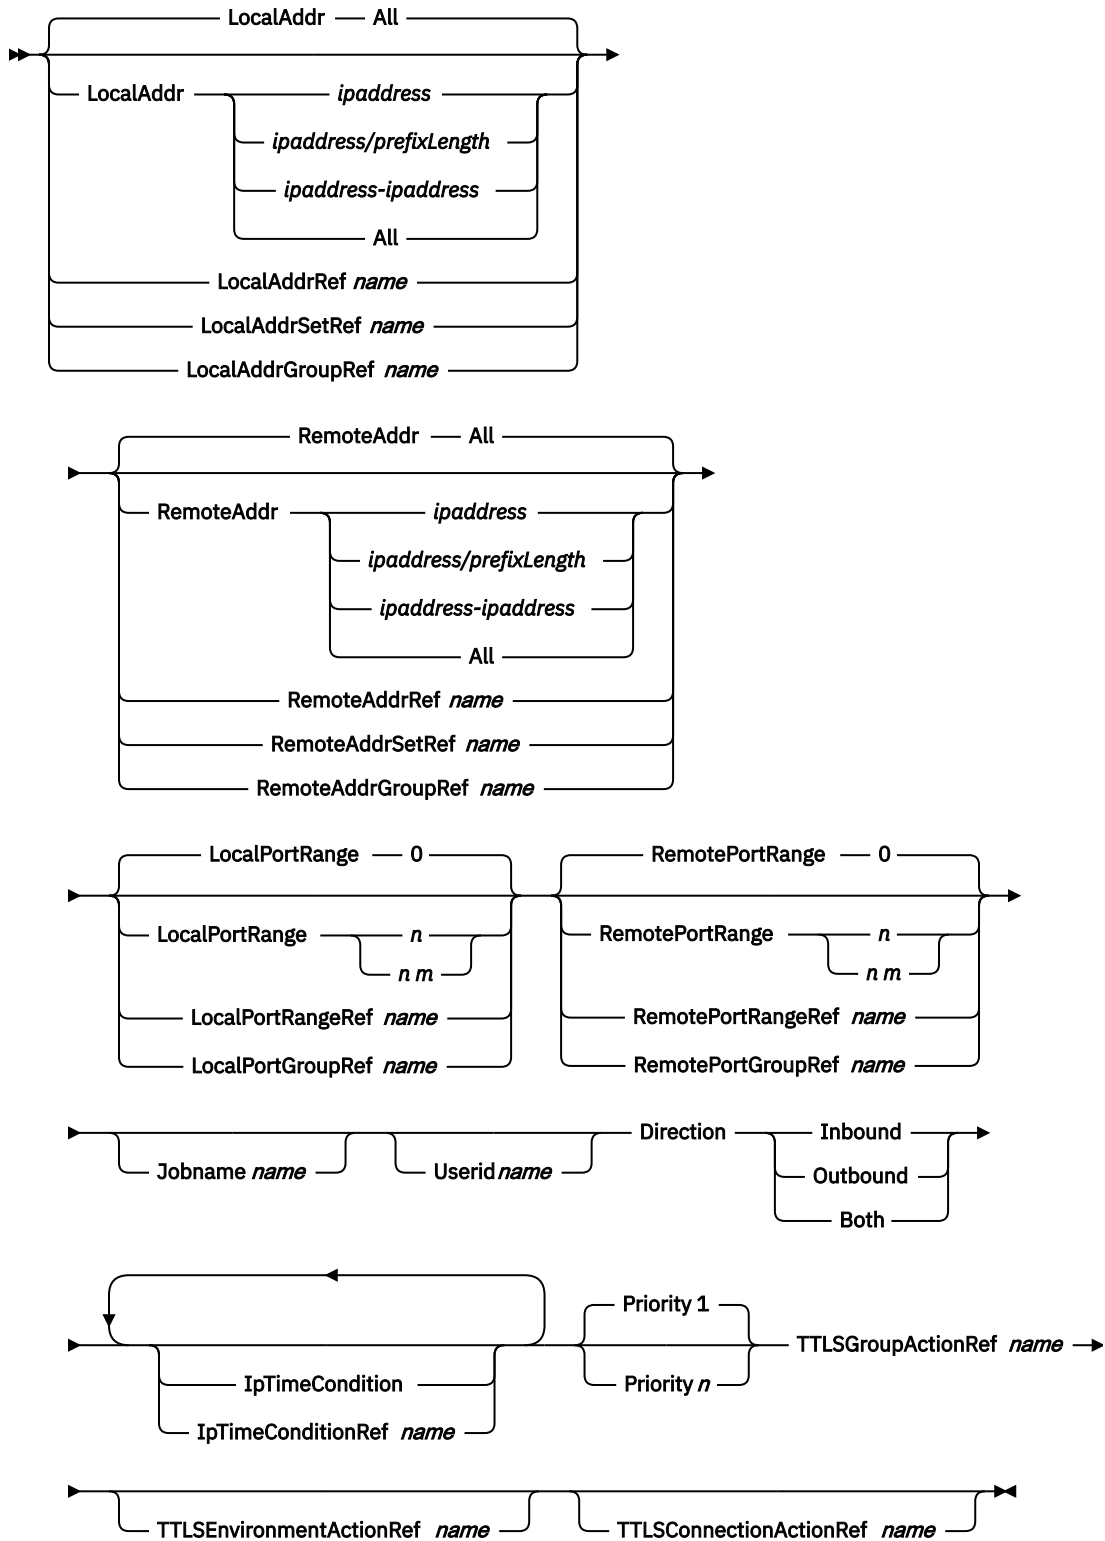

Syntax

➤ TTLRule — *name* — Put Braces and Parameters on Separate Lines ➤

Put Braces and Parameters on Separate Lines

➤ {
 TTLRule Parameters
} ➤

TTLRule Parameters

Parameters

name

A string 1 - 32 characters in length specifying the name of this TTLRule statement.

LocalAddr

A local IP address the application is using for the connection that must match for this rule's action to be performed. The application can be explicitly bound to the IP address, or it can be chosen by the TCP/IP stack.

All

Any local IP address matches this rule.

ipaddress

A single IP address.

ipaddress/prefixLength

The number of unmasked leading bits in the *ipaddress* value. The *prefixLength* value can be in the range 0 - 32 for IPv4 addresses and 0 - 128 for IPv6 addresses. An IP address matches this condition if its unmasked bits are identical to the unmasked bits defined.

ipaddress-ipaddress

A range of IP addresses.

Tip: To create a rule that matches only on local IPv4 addresses, code 0.0.0.0/0. To create a rule that matches only on local IPv6 addresses, code ::/0.

LocalAddrRef

The name of a globally defined IpAddr statement to be used for the local IP address specification.

LocalAddrSetRef

The name of a globally defined IpAddrSet statement to be used for the local IP address prefix or range specification.

LocalAddrGroupRef

The name of a globally defined IpAddrGroup statement to be used for the local IP address specification.

RemoteAddr

A remote IP address specification that must match for this rule's action to be performed.

All

Any remote IP address matches this rule.

ipaddress

A single IP address.

ipaddress/prefixLength

The number of unmasked leading bits in the *ipaddress* value. The *prefixLength* value can be in the ranges of 0 - 32 for IPv4 addresses and 0 - 128 for IPv6 addresses. An IP packet matches this condition if its unmasked bits are identical to the unmasked bits defined.

ipaddress-ipaddress

A range of IP addresses.

Tip: To create a rule that matches only on remote IPv4 addresses, code 0.0.0.0/0. To create a rule that matches only on remote IPv6 addresses, code ::/0.

RemoteAddrRef

The name of a globally defined IpAddr statement to be used for the remote IP address specification.

RemoteAddrSetRef

The name of a globally defined IpAddrSet statement to be used for the remote IP address prefix or range specification.

RemoteAddrGroupRef

The name of a globally defined IpAddrGroup statement to be used for the remote IP address specification.

LocalPortRange

A local port the application is bound to for this rule's action to be performed.

Valid values for *n* are in the range 0 - 65535. If 0 is specified for *n* then the rule applies to any local port. If *n* is specified as the beginning value for a range, then 0 is not a valid value.

If an *m* value is specified, it must be greater than or equal to *n* and less than 65536.

Rule: Include a blank, a colon (:), or a dash (-) as a delimiter.

LocalPortRangeRef

The name of a globally defined PortRange statement to be used for the local port specification.

LocalPortGroupRef

The name of a globally defined PortGroup statement to be used for the local port specification.

RemotePortRange

A remote port the application must be connecting to for this rule's action to be performed.

Valid values for *n* are in the range 0 - 65535. If 0 is specified for *n*, then the rule applies to any remote port. If *n* is specified as the beginning value for a range, then 0 is not a valid value.

If an *m* value is specified, then it must be greater than or equal to *n* and less than 65536.

Rule: Include a blank, a colon (:), or a dash (-) as a delimiter.

RemotePortRangeRef

The name of a globally defined PortRange statement to be used for the remote port specification.

RemotePortGroupRef

The name of a globally defined PortGroup statement to be used for the remote port specification.

Jobname

The *name* value specifies the job name of the application. This optional value specifies that, when the traffic is mapped to an AT-TLS security level, a packet must be flowing to or from an application with this job name for that packet to match the set of traffic characteristics. The *name* value must be 1 to 8 characters in length. It cannot include blanks or the "#" characters. A trailing asterisk indicates a wildcard specification. The specified job name is not case sensitive, and is translated to uppercase before being compared.

Userid

The *name* value specifies the corresponding user name. This optional value specifies that, when the traffic is mapped to an AT-TLS security level, a packet must be flowing to or from an application that is running under this user ID for that packet to match the set of traffic characteristics. The *name* value must be 1 to 8 characters in length. It cannot include blanks or the "#" characters. A trailing asterisk indicates a wildcard specification. The specified user ID is not case sensitive, and is translated to uppercase before being compared.

Direction

Specifies the direction the connection must be initiated from for this rule's action to be performed.

Inbound

A connection request has arrived inbound to the local host. An application must do an accept to service this connection.

Outbound

A connection request is being initiated by the local host. An application must have done a connect to initiate this connection.

Both

Inbound and Outbound connection requests match this rule.

IpTimeCondition

An inline specification of a IpTimeCondition statement. There is a limit of 25 IpTimeCondition specifications on the TTLSRule statement.

IpTimeConditionRef

The name of a globally defined IpTimeCondition statement. There is a limit of 25 IpTimeCondition references on the TTLSRule statement.

Priority

An integer value in the range 1 - 2000000000 that represent the priority associated with the rule. The highest priority value is 2000000000.

Only one rule is ever mapped per connection. Rules are searched for a match starting at the highest priority, so if multiple rules could possibly be matched for a connection, the rule with the highest priority is matched first. If multiple rules of the same priority match, the rule that is mapped is difficult to predict. If this attribute is not specified, the default priority is 1.

Guideline: When setting the priority for multiple rules, do not set the priority as a sequential value, for example, 2, 3, 4, 5. Instead, set the priority to provide space to change the priority or to insert additional rules, such that this rule is preferred over another rule, without duplicating a priority. For example, the priorities could be configured as 20, 30, 40, 50.

TTLSTLSGroupActionRef

The name of a globally defined TTLSTLSGroupAction statement.

TTLSTLSEnvironmentActionRef

The name of a globally defined TTLSTLSEnvironmentAction statement.

TTLSTLSConnectionActionRef

The name of a globally defined TTLSTLSConnectionAction statement.

Rules:

- One of the following values must be specified:
 - Local address
 - Remote address
 - Local port
 - Remote port
 - Job name
 - Userid
- A TTLSTLSEnvironmentActionRef is required if the TTLSTLSGroupAction specifies TTLSEnabled as **On**.
- CNF logic is used to evaluate complex AT-TLS rules (rules containing multiple conditions). For a detailed description of AT-TLS condition evaluation using CNF logic, see [z/OS Communications Server: IP Configuration Guide](#). An AT-TLS condition is comprised of the following values from the TTLSTLSRule statement:
 - Local IP Address
 - Remote IP Address
 - Local Port
 - Remote Port
 - Jobname
 - Userid
 - Service Direction

TTLSTLSSignatureParms statement

Use the TTLSTLSSignatureParms statement to define the client and server elliptic curve preferences and the client signature algorithm pair specifications for an AT-TLS environment or an AT-TLS connection. A TTLSTLSSignatureParms statement can be specified inline in a TTLSTLSEnvironmentAction or TTLSTLSConnectionAction statement or referenced by a TTLSTLSEnvironmentAction or TTLSTLSConnectionAction statement.

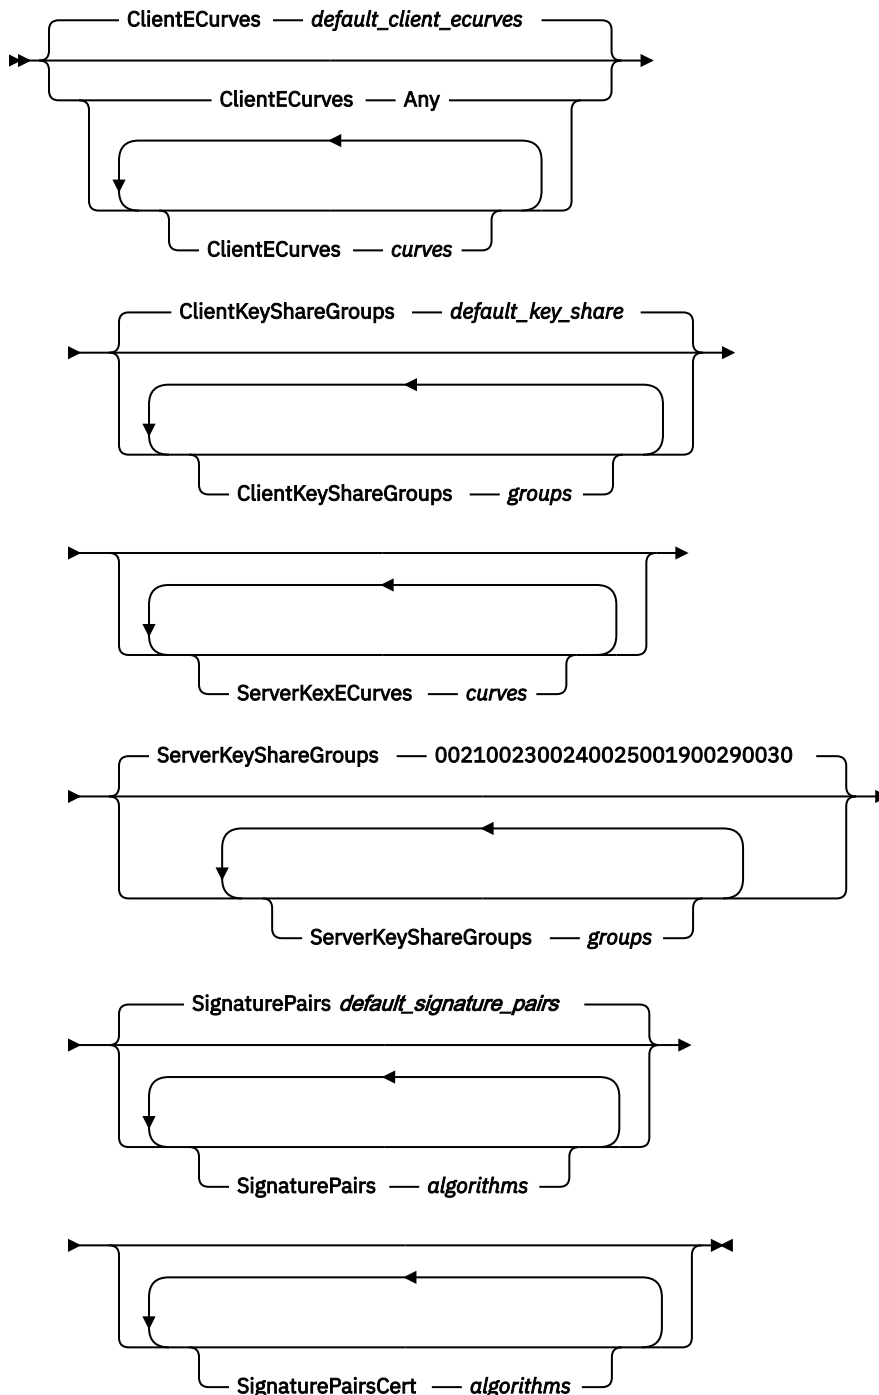

Syntax

Put Braces and Parameters on Separate Lines

TTLSSignatureParms Parameters

Parameters

If an unspecified parameter has a defined default value, the parameter will reflect the default value even if it is not applicable for the rule/action that references the TTLSSignatureParms statement. For example, the ClientKeyShareGroups and ServerKeyShareGroups are only used when TLSv1.3 is

negotiated. However, they have default values that are always set even if the rule referencing the TTLSSignatureParms does not have TLSv1.3 enabled.

name

A string 1 - 32 characters in length that specifies the name of this TTLSSignatureParms statement.

Rule: If this TTLSSignatureParms statement is not specified inline in another statement, a *name* value must be provided. If a name is not specified for an inline TTLSSignatureParms statement, a nonpersistent system name is created.

ClientECurves

Specifies the list of ECDH (Elliptic curve Diffie-Hellman) curves that are supported by the client, in order of preference for use.

- For TLSv1.0, TLSv1.1, TLSv1.2: This list is used by the client to guide the server as to which elliptical curves are preferred when using cipher suites that use elliptical curve cryptography.
- For TLSv1.3: This list is used by the client to guide the server as to which elliptic curves are preferred and to guide group selection for encryption and decryption of handshake messages.

Only NIST recommended curves along with x25519 and x448 can be specified.

Restriction: For TLSv1.0, TLSv1.1, and TLSv1.2, if x25519 or x448 is specified and the partner is using an ECDSA certificate, the certificate's elliptic curve must also be included in the ClientECurves list of curves. AT-TLS does not support X25519 and x448 certificates.

For TLSv1.0, TLSv1.1, and TLSv1.2, to allow the use of Brainpool standard curve certificates for a TLS connection, the list must contain only the ANY curve name constant.

Restriction: Brainpool certificates cannot be used in FIPS mode or if the negotiated protocol is TLSv1.3.

Restriction: When TLSv1.3 is enabled, a value of ANY will result in a failure.

If a ClientECurves parameter is specified more than once, the values are concatenated to create a single list of elliptic curve enumerators. The ANY curve name constant cannot be specified in combination with any specific curve values. For System SSL, the GSK_CLIENT_ECURVE_LIST value is set to the concatenated value or to NULL if ANY is specified.

The *curves* value is a string of one or more 4-character curve enumerators or a single curve name constant. The curve string cannot have blanks between the curve enumerators. If duplicate curves are specified, the first instance is used and all other instances are ignored. The maximum number of curves is 16. For System SSL, see *Table 16. Supported elliptic curve (group) definitions for TLS V1.0, TLS V1.1, TLS V1.2, and TLS V1.3 and supported key share definitions for TLS V1.3* in [z/OS Cryptographic Services System SSL Programming](#) for a list of valid elliptic curves and the TLS versions for which the curves are supported. [Table 78 on page 959](#) lists the supported elliptic curve name constants.

default_client_ecurves

For an environment action, the default is dependent on whether TLSv1.3 is enabled for the environment action or not.

- If TLSv1.3 is enabled for the environment action, the default is 002300240025002100190029 which includes secp256r1, secp384r1, secp521r1, secp224r1, secp192r1, x25519.
- If TLSv1.3 is not enabled for the environment action, the default is 00230024002500210019 which includes secp256r1, secp384r1, secp521r1, secp224r1, secp192r1.

For a connection action, if the TLSv1.3 parameter is explicitly configured for the connection action, the default is determined as follows:

- If TLSv1.3 is enabled for the connection action, the default is 002300240025002100190029 which includes secp256r1, secp384r1, secp521r1, secp224r1, secp192r1, x25519.
- If TLSv1.3 is disabled for the connection action, the default is 00230024002500210019 which includes secp256r1, secp384r1, secp521r1, secp224r1, secp192r1.

- Otherwise, if TLSv1.3 is not configured for the connection action, there is no default and the setting is determined by the associated environment action.

<i>Table 78. ClientECurves/ ServerKexECurves</i>		
Elliptic curve name constants	Elliptic Curve Enumerator	Supported TLS versions
secp192r1	0019	TLS V1.0, V1.1, V1.2
secp224r1	0021	TLS V1.0, V1.1, V1.2
secp256r1	0023	TLS V1.0, V1.1, V1.2, V1.3
secp384r1	0024	TLS V1.0, V1.1, V1.2, V1.3
secp521r1	0025	TLS V1.0, V1.1, V1.2, V1.3
x25519	0029	TLS V1.0, V1.1, V1.2, V1.3
x448	0030	TLS V1.0, V1.1, V1.2, V1.3

<i>Table 79. ClientKeyShareGroups/ServerKeyShareGroups for TLSv1.3</i>	
Elliptic curve name constants	Elliptic Curve Enumerator
secp256r1	0023
secp384r1	0024
secp521r1	0025
x25519	0029
x448	0030

Requirement: Elliptic Curve requires ICSF to be active. See *Elliptic Curve Cryptography Support* in *z/OS Cryptographic Services System SSL Programming* for more information.

ClientKeyShareGroups

Specifies the list of key share groups supported by the client during a TLSv1.3 handshake. During a TLSv1.3 handshake, the client sends key shares for the groups in this list that are in common and in the same order as the supported groups list (ClientECurves *curves*). The server selects a group based on the client's preferred order and the key share groups that it supports. The client and server use the selected group to encrypt and decrypt TLSv1.3 handshake messages.

The *groups* value is a string of one or more 4-character group enumerators or a single group name constant. The groups string cannot have blanks between the group enumerators. If duplicate groups are specified, the first instance is used and all other instances are ignored. The maximum number of groups is 16. See [Table 79 on page 959](#) for a list of the elliptic curve name constants supported for ClientKeyShareGroups.

If a ClientKeyShareGroups parameter is specified more than once, the values are concatenated to create a single list of groups enumerators. For System SSL, the GSK_CLIENT_TLS_KEY_SHARES value is set to the concatenated value.

For System SSL, see [Table 16. Supported elliptic curve \(group\) definitions for TLS V1.0, TLS V1.1, TLS V1.2, and TLS V1.3 and supported key share definitions for TLS V1.3 in z/OS Cryptographic Services System SSL Programming](#) for a list of valid elliptic curves and the TLS versions for which the group is supported. [Table 79 on page 959](#) lists the supported key share group constants.

default_key_share

For an environment action, the default value for ClientKeyShareGroups is the first value in the ClientECurves list that is supported for TLSv1.3. For example, if the default value for ClientECurves is used then the default value for ClientKeyShareGroups is 0023.

For a connection action, if ClientECurves is specified or defaulted, the default value for ClientKeyShareGroups is the first value in the configured ClientECurves list that is supported for TLSv1.3. Otherwise, there is no default and the setting is determined by the associated environment action.

ServerKexECurves

Specifies the list of ECDH (Elliptic curve Diffie-Hellman) curves that are supported by the server during a TLS V1.0, TLS V1.1, or TLS V1.2 handshake. This list is used by the server to limit which elliptic curves can be used for the handshake key exchange when an ephemeral ECDH cipher (TLS_ECDHE_XXX) is utilized.

The *curves* value is a string of one or more 4-character curve enumerators or a single curve name constant. The curve list cannot have blanks between the curve enumerators. If duplicate curves are specified, the first instance is used, and all other instances are ignored.

If a ServerKexECurves parameter is specified more than once, the values are concatenated to create a single list of curve enumerators. For System SSL, the GSK_SERVER_ALLOWED_KEX_ECURLS value is set to the concatenated value.

For System SSL, see *Table 29. Supported elliptic curve (group) definitions for TLS V1.0, TLS V1.1, TLS V1.2, and TLS V1.3 and supported key share definitions for TLS V1.3* in *z/OS Cryptographic Services System SSL Programming* for a list of valid elliptic curves and the TLS versions for which the curve is supported. [Table 78 on page 959](#) lists the supported elliptic curve name constants.

There is no default for the ServerKexECurves parameter.

ServerKeyShareGroups

Specifies the list of key share groups that are supported by the server during a TLSv1.3 handshake. During a TLSv1.3 handshake, the server uses the client's preferred key share group order and selects a group that it supports (as defined by ServerKeyShareGroups). The client and server use the selected group to encrypt and decrypt TLSv1.3 handshake messages.

The *groups* value is a string of one or more 4-character group enumerators or a single group name constant. The groups string cannot have blanks between the group enumerators. If duplicate groups are specified, the first instance is used and all other instances are ignored. The maximum number of groups is 16. See [Table 79 on page 959](#) for a list of the key share group constants.

If a ServerKeyShareGroups parameter is specified more than once, the values are concatenated to create a single list of group enumerators. For System SSL, the GSK_SERVER_TLS_KEY_SHARES value is set to the concatenated value.

For System SSL, see *Table 16. Supported elliptic curve (group) definitions for TLS V1.0, TLS V1.1, TLS V1.2, and TLS V1.3 and supported key share definitions for TLS V1.3* in *z/OS Cryptographic Services System SSL Programming* for a list of valid elliptic curves and the TLS versions for which the group is supported. [Table 79 on page 959](#) lists the supported key share group constants.

For an environment action, the default value for ServerKeyShareGroups is 00230024002500290030 which includes secp256r1, secp384r1, secp521r1, x25519, x448.

For a connection action, there is no default for ServerKeyShareGroups - the setting is determined by the associated environment action.

SignaturePairs

Specifies the signature algorithm pairs that are supported by the client or server for use in digital signatures of X.509 certificates and TLS handshake messages. These pairs are sent by either the client or server to the session partner to indicate which signature algorithm pairs are supported. If a SignaturePairsCert parameter(s) is specified, the SignaturePairs parameter(s) setting is only used for validating TLS handshake messages. SignaturePairs specification only has relevance for sessions using TLSv1.2 or later.

If a SignaturePairs parameter is specified more than once, the values are concatenated to create a single list of signature algorithm pairs. For System SSL, the GSK_TLS_SIG_ALG_PAIRS value is set to the concatenated value.

The *algorithms* value is a string of one or more 4-character signature algorithm pairs or a single signature algorithm pair constant. The algorithm string cannot have blanks between each signature algorithm pair. If duplicate signature algorithm pairs are specified, the first instance is used and all other instances are ignored. The maximum number of signature algorithm pairs is 64. For System SSL, see *Table 17. Signature algorithm pair and certificate signature pair definitions for TLS V1.2 and TLS V1.3* in *z/OS Cryptographic Services System SSL Programming* for a list of valid signature algorithm pairs. *Table 80* on page 961 lists the supported signature algorithm pair constants and the TLS versions for which they are supported.

default_signature_pairs

For an environment action, the default is dependent on whether TLSv1.3 is enabled for the environment action or not.

- If TLSv1.3 is enabled for the environment action, the default is 060106030501050304010403080608050804 which includes the following:
 - TLS_SIGALG_SHA512_WITH_RSA, TLS_SIGALG_SHA512_WITH_ECDSA,
 - TLS_SIGALG_SHA384_WITH_RSA, TLS_SIGALG_SHA384_WITH_ECDSA,
 - TLS_SIGALG_SHA256_WITH_RSA, TLS_SIGALG_SHA256_WITH_ECDSA,
 - TLS_SIGALG_SHA512_WITH_RSASSA_PSS,
 - TLS_SIGALG_SHA384_WITH_RSASSA_PSS,
 - TLS_SIGALG_SHA256_WITH_RSASSA_PSS.
- If TLSv1.3 is not enabled for the environment action, the default is 060106030501050304010403 which does not include the following:
 - TLS_SIGALG_SHA512_WITH_RSASSA_PSS,
 - TLS_SIGALG_SHA384_WITH_RSASSA_PSS,
 - TLS_SIGALG_SHA256_WITH_RSASSA_PSS.

For a connection action, if the TLSv1.3 parameter is explicitly configured for the connection action, the default is determined as follows:

- If TLSv1.3 is enabled for the connection action, the default is 060106030501050304010403080608050804.
- If TLSv1.3 is disabled for the connection action, the default is 060106030501050304010403.
- Otherwise, if TLSv1.3 is not configured for the connection action, there is no default and the setting is determined by the associated environment action.

<i>Table 80. SignaturePairs/ SignaturePairsCert</i>		
Signature algorithm pair constant	Hexadecimal characters	Supported TLS Versions
TLS_SIGALG_MD5_WITH_RSA	0101	TLS V1.2
TLS_SIGALG_SHA1_WITH_RSA	0201	TLS V1.2
TLS_SIGALG_SHA1_WITH_DSA	0202	TLS V1.2
TLS_SIGALG_SHA1_WITH_ECDSA	0203	TLS V1.2
TLS_SIGALG_SHA224_WITH_RSA	0301	TLS V1.2
TLS_SIGALG_SHA224_WITH_DSA	0302	TLS V1.2
TLS_SIGALG_SHA224_WITH_ECDSA	0303	TLS V1.2

<i>Table 80. SignaturePairs/ SignaturePairsCert (continued)</i>		
Signature algorithm pair constant	Hexadecimal characters	Supported TLS Versions
TLS_SIGALG_SHA256_WITH_RSA	0401	TLS V1.2, V1.3
TLS_SIGALG_SHA256_WITH_DS	0402	TLS V1.2
TLS_SIGALG_SHA256_WITH_ECDSA	0403	TLS V1.2, V1.3
TLS_SIGALG_SHA384_WITH_RSA	0501	TLS V1.2, V1.3
TLS_SIGALG_SHA384_WITH_ECDSA	0503	TLS V1.2, V1.3
TLS_SIGALG_SHA512_WITH_RSA	0601	TLS V1.2, V1.3
TLS_SIGALG_SHA512_WITH_ECDSA	0603	TLS V1.2, V1.3
TLS_SIGALG_SHA256_WITH_RSASSA_PSS	0804	TLS V1.2, V1.3
TLS_SIGALG_SHA384_WITH_RSASSA_PSS	0805	TLS V1.2, V1.3
TLS_SIGALG_SHA512_WITH_RSASSA_PSS	0806	TLS V1.2, V1.3

SignaturePairsCert

Specifies the signature algorithm pairs that are supported by the client or server for use in digital signatures of X.509 certificates. These pairs can be sent by either the client or server to the session partner to indicate which signature algorithm pairs are supported. The SignaturePairsCert parameter(s) setting overrides the SignaturePairs parameter(s) setting when checking the digital signatures of the peer's X.509 certificates.

SignaturePairsCert specification only has relevance for sessions using TLSv1.3 or later.

If a SignaturePairsCert parameter is specified more than once, the values are concatenated to create a single list of signature algorithm pairs. For System SSL, the GSK_TLS_CERT_SIG_ALG_PAIRS value is set to the concatenated value. If not specified, the GSK_TLS_SIG_ALG_PAIRS setting (from the SignaturePairs parameter) is used to indicate which signature algorithm pairs the client or server supports for use in digital signatures of X.509 certificates.

The *algorithms* value is a string of one or more 4-character signature algorithm pairs or a single signature algorithm pair constant. The algorithm string cannot have blanks between each signature algorithm pair. If duplicate signature algorithm pairs are specified, the first instance is used and all other instances are ignored. The maximum number of signature algorithm pairs is 64. For System SSL, see [Table 17. Signature algorithm pair and certificate signature pair definitions for TLS V1.2 and TLS V1.3 in z/OS Cryptographic Services System SSL Programming](#) for a list of valid signature algorithm pairs. [Table 80 on page 961](#) lists the supported signature algorithm pair constants and the TLS versions for which they are supported.

IDS policy statements

This topic contains information about the following IDS policy statements:

- “IDSAction statement” on page 963
- “IDSAttackCondition statement” on page 965
- “IDSExclusion statement” on page 974
- “IDSReportSet statement” on page 975
- “IDSRule statement” on page 978
- “IDSScanEventCondition statement” on page 980
- “IDSScanExclusion statement” on page 983
- “IDSScanGlobalCondition statement” on page 984
- “IDSTRCondition statement” on page 985

IDSAction statement

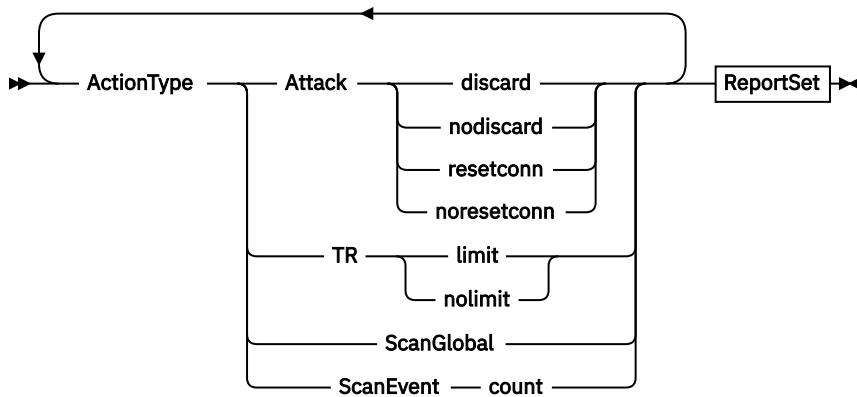

Use the IDSAction statement to define the action taken by the IDS rule. This statement is associated with an IDS rule with the same ActionType value.

► IDSAction — *name* — Put Braces and Parameters on Separate Lines ◀

Put Braces and Parameters on Separate Lines

IDSAction Parameters

ReportSet

Parameters

name

A string 1 - 32 characters in length that specifies the name of this IDSAction statement.

ActionType

Indicates the type of IDS action associated with a policy rule.

Attack

Indicates that this is an attack action.

Discard

Discard packets that match the associated rule.

NoDiscard

Do not discard packets that match the associated rule.

ResetConn

Reset the TCP connection or connections associated with the attack.

Restriction: This value is valid only for V1R13 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details.

NoResetConn

Do not reset the TCP connection or connections associated with the attack.

Restriction: This value is valid only for V1R13 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details.

Rules:

- The Discard and NoDiscard values are valid for the following attack types:
 - DATA_HIDING
 - ICMP_REDIRECT
 - IP_FRAGMENT
 - OUTBOUND_RAW
 - OUTBOUND_RAW_IPV6
 - PERPETUAL_ECHO
 - RESTRICTED_IP_OPTIONS
 - RESTRICTED_IP_PROTOCOL
 - RESTRICTED_IPV6_DST_OPTIONS
 - RESTRICTED_IPV6_HOP_OPTIONS
 - RESTRICTED_IPV6_NEXT_HDR
 - FLOOD (NoDiscard is ignored because the stack always discards packets associated with a flood.)
 - MALFORMED_PACKET (NoDiscard is ignored because the stack always discards malformed packets.)
 - EE_MALFORMED_PACKET
 - EE_PORT_CHECK
 - EE_LDLC_CHECK
 - EE_XID_FLOOD (The Discard value is not valid. Use the NoDiscard value.)

The Discard and NoDiscard values are ignored for all other attack types. For more information, see [“IDSAttackCondition statement”](#) on page 965.

- The ResetConn and NoResetConn values are valid for the following attack types:
 - TCP_QUEUE_SIZE
 - GLOBAL_TCP_STALL

ResetConn and NoResetConn will be ignored for all other attack types. For more information, see [“IDSAttackCondition statement”](#) on page 965.

- An IDSAction statement can include two ActionType attack parameters, one with the action Discard or NoDiscard and the other with the action ResetConn or NoResetConn. If more than one ActionType attack parameter is coded with the action Discard or NoDiscard, the last action is used. If more than one ActionType attack parameter is coded with the action ResetConn or NoResetConn, the last action is used.

ScanGlobal

Indicates that this is a scan global action that specifies global scan detection values.

ScanEvent count

Indicates that this is a scan event action for individual scan detection.

count

Increment the scan event counter for this rule.

TR

Indicates that this is a traffic regulation action.

Limit

For TCP, this value prevents connections, for UDP, it limits the length of inbound UDP queues.

NoLimit

No limits are placed on the number of TCP connections or the length of inbound UDP queues.

Rule: If you specify more than one ActionType TR parameter, the setting from the last parameter that you specified is used.

IDSReportSet

An inline specification of an IDSReportSet statement.

IDSReportSetRef *name*

The name of a globally defined IDSReportSet statement.

Rules:

- The IDSReportSet parameter is allowed for all ActionType values. However, it has no effect if specified for ActionType ScanEvent.
- Not all parameters specified on the IDSReportSet statement apply to all ActionType values. Such values are ignored by the stack when not applicable to the IDS policy.

IDSAttackCondition statement

Use the IDSAttackCondition statement for attack detection, reporting, and prevention. There are several attack types. For each attack type, the single highest priority rule is used.

The IDSAttackCondition statement can specify values for LocalPortRange, RemotePortRange, or both, or these values can be specified with references to global definitions on the PortRange or PortGroup statements.

The IDSAttackCondition statement can specify values for ProtocolRange, or this value can be specified with a reference to global definitions on the IPProtocolRange or IPProtocolGroup statements.

The IDSAttackCondition statement can specify values for the RestrictedIpOptionRange parameter, or this value can be specified with a reference to global definitions on the IpOptionRange or IpOptionGroup statements.

The IDSAttackCondition statement can specify values for the IPv6NextHdrRange parameter, or this value can be specified with a reference to global definitions on the IPv6NextHdrRange or IPv6NextHdrGroup statements.

The IDSAttackCondition statement can specify values for the RestrictedIpv6OptionRange parameter, or this value can be specified with a reference to global definitions on the IpOptionRange or IpOptionGroup statements.

The IDSAttackCondition statement can contain an inline definition of an IDSExclusion, or this value can be specified with a reference to a global definition of an IDSExclusion statement.

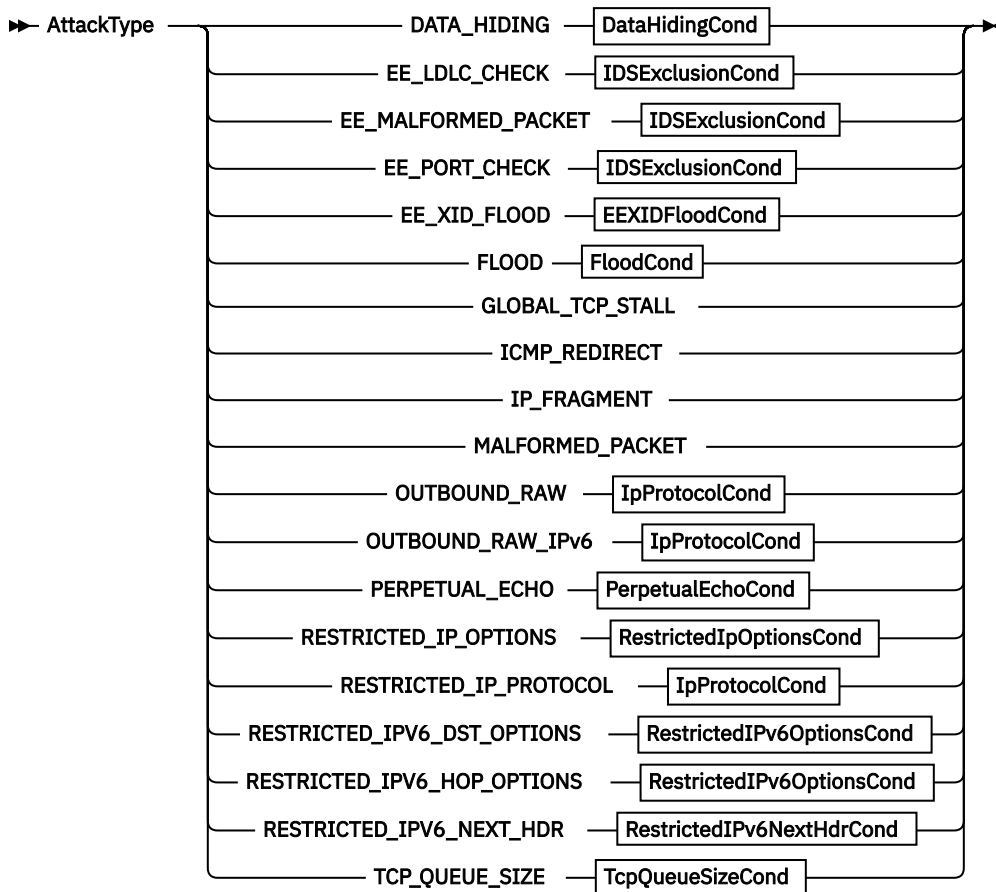

Syntax

Put Braces and Parameters on Separate Lines

IDSAttackCondition Parameters

DataHidingCond

EEXIDFloodCond

FloodCond

IDSExclusionCond

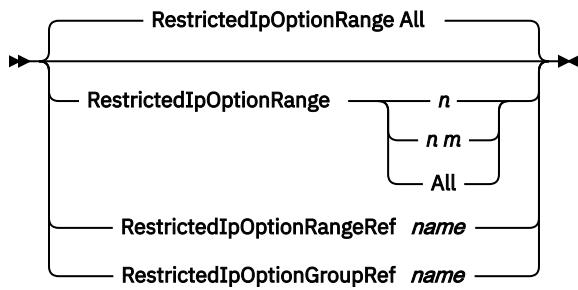

IpProtocolCond

PerpetualEchoCond

RestrictedIPOptionsCond

RestrictedIPv6OptionsCond

RestrictedIPv6NextHdrCond

TcpQueueSizeCond

Parameters

name

A string 1 - 32 characters in length that specifies the name of this IDSAttackCondition statement.

Rule: If this IDSAttackCondition statement is not specified inline within another statement, *name* must be provided.

If a name is not specified for an inline IDSAttackCondition statement, a nonpersistent system name is created.

AttackType

DATA_HIDING

Indicates that the rule is for detecting hidden data. The DATA_HIDING attack type applies to both IPv4 and IPv6 inbound packets.

Restriction: This value is valid only for V1R13 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details.

EE_MALFORMED_PACKET

Indicates that the rule is for EE malformed packets. The packets can be discarded by TCP/IP or forwarded to VTAM. The EE_MALFORMED_PACKET attack type applies to both IPv4 and IPv6 malformed packets.

Restriction: This value is valid only for V1R13 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details.

EE_PORT_CHECK

Indicates that the rule checks the source port number for inbound Enterprise Extender (EE) packets. The source port number must be the same as the destination port number. The EE_PORT_CHECK attack type applies to both IPv4 and IPv6 packets.

Restriction: This value is valid only for V1R13 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details.

EE_LDLC_CHECK

Indicates that the rule is for LDLC control commands received on a port other than the signalling port. The EE_LDLC_CHECK attack type applies to both IPv4 and IPv6 packets.

Restriction: This value is valid only for V1R13 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details.

EE_XID_FLOOD

Indicates that the rule is for an EE XID flood attack. The EE_XID_FLOOD attack type applies to both IPv4 and IPv6.

Restriction: This value is valid only for V1R13 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details.

FLOOD

Indicates that the rule is for flooding attacks. For FLOOD attacks, the packets are always discarded regardless of what ActionType is configured on the IDSAction. The FLOOD attack type applies to both IPv4 and IPv6.

GLOBAL_TCP_STALL

Indicates that the rule is to detect an attack that causes a large number of TCP connections to be stalled and unable to send data. The GLOBAL_TCP_STALL attack type applies to both IPv4 and IPv6 connections.

Results:

- A global TCP stall condition is detected for a TCP/IP stack when at least 50% of the active TCP connections are stalled and at least 1000 TCP connections are active.
- When the condition is detected, the stalled TCP connections are reset if the policy action specifies resetconn.
- When the condition is detected, a syslogd message is generated for each stalled connection if TypeActions Log LogDetail is specified. Message EZZ8673I is generated if the stalled connection is reset. Otherwise, message EZZ8674I is generated.

Restriction: This value is valid only for V1R13 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details.

ICMP_REDIRECT

Indicates that the rule is for ICMP redirect detection. This includes both ICMP redirects and ICMPv6 redirects.

IP_FRAGMENT

Indicates that the rule is for detecting suspicious fragmented packets (fragments that overlay and change data in the packet, including changes to the length of the packet).

MALFORMED_PACKET

Indicates that the rule is for a number of specific malformed packets that are detected on inbound traffic. For MALFORMED_PACKET attacks, the packets are always discarded regardless of what ActionType is configured on the IDSAction. The MALFORMED_PACKET attack type applies to both IPv4 and IPv6 inbound packets.

OUTBOUND_RAW

Indicates that the rule is to enforce restrictions on the use of IPv4 RAW sockets for outbound processing, which prevents this stack from being used to attack other systems. A list of restricted IP protocols is also specified in the rule's conditions.

Restriction: The OUTBOUND_RAW attack type applies only to IPv4 packets. The OUTBOUND_RAW_IPV6 attack type provides analogous function for IPv6 packets.

OUTBOUND_RAW_IPV6

Indicates that the rule is to enforce restrictions on the use of IPv6 RAW sockets for outbound processing, which prevents this stack from being used to attack other systems. A list of restricted protocols is also specified in the rule's conditions.

Rule: IPv6 policy is installed but is not enforceable in a stack that is not IPv6 enabled.

Restrictions:

- The OUTBOUND_RAW_IPV6 attack type applies only to IPv6 packets. The OUTBOUND_RAW attack type provides analogous function for IPv4 packets.
- This value is valid only for V1R13 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details.

PERPETUAL_ECHO

Indicates that the rule is to prevent perpetual echos over UDP ports. A list of local UDP ports that always respond to an input packet is also specified in the rule's conditions, and a separate list of remote (network) UDP ports that always respond is specified. The PERPETUAL_ECHO attack type applies to both IPv4 and IPv6 packets.

Rule: For PERPETUAL_ECHO attacks, only the first 20 ports specified in the local list and in the remote list are used.

RESTRICTED_IP_OPTIONS

Indicates that the rule is to detect inbound IPv4 packets that have IP options that are not allowed. A list of restricted IP options is also specified in the rule's conditions.

For RESTRICTED_IP_OPTIONS attacks, if no option ranges are specified, all options are restricted. Option 0 (end of option list) and 1 (no-operation) are always allowed; they are ignored if present in the list of restricted IP options.

Restriction: The RESTRICTED_IP_OPTIONS attack type applies only to IPv4 packets. The RESTRICTED_IPV6_NEXT_HDR, RESTRICTED_IPV6_DST_OPTIONS, and RESTRICTED_IPV6_HOP_OPTIONS attack types provide analogous function for IPv6 packets.

RESTRICTED_IP_PROTOCOL

Indicates that the rule is to detect inbound IPv4 packets that have IP protocols that are not allowed. A list of restricted IP protocols is also specified in the rule's conditions.

For RESTRICTED_IP_PROTOCOL attacks, Protocol 1 (ICMP), 6 (TCP), and 17 (UDP) are ignored if present in the list of restricted IP protocols.

Restrictions:

- The RESTRICTED_IP_PROTOCOLS attack type applies only to IPv4 packets. The RESTRICTED_IPV6_NEXT_HDR attack type provides analogous function for IPv6 packets.
- The RESTRICTED_IP_PROTOCOLS attack type applies only to unicast packets destined for an interface on this TCP/IP stack. It does not apply to broadcast or multicast packets. It does not apply to routed traffic.

RESTRICTED_IPV6_DST_OPTIONS

Indicates that the rule is to detect inbound IPv6 packets that have an IPv6 destination options extension header with options that are not allowed. A list of restricted IPv6 destination option values is specified in the rule's conditions.

Rule: IPv6 policy is installed but is not enforceable in a stack that is not IPv6 enabled.

Restrictions:

- The RESTRICTED_IPV6_DST_OPTIONS attack type applies only to IPv6 packets. The RESTRICTED_IP_OPTIONS attack type provides analogous function for IPv4 packets.
- You cannot restrict options 0 (Pad1) or 1 (PadN).
- This value is valid only for V1R13 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details.

RESTRICTED_IPV6_HOP_OPTIONS

Indicates that the rule is to detect inbound IPv6 packets that have an IPv6 hop-by-hop options extension header with options that are not allowed. A list of restricted IPv6 hop-by-hop option values is specified in the rule's conditions.

Rule: IPv6 policy is installed but is not enforceable in a stack that is not IPv6 enabled.

Restrictions:

- The RESTRICTED_IPV6_HOP_OPTIONS attack type applies only to IPv6 packets. The RESTRICTED_IP_OPTIONS attack type provides analogous function for IPv4 packets.
- You cannot restrict options 0 (Pad1) or 1 (PadN).
- This value is valid only for V1R13 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details.

RESTRICTED_IPV6_NEXT_HDR

Indicates that the rule is to detect inbound IPv6 packets that have a next header value that is not allowed. A list of restricted IPv6 next header values is specified in the rule's conditions. The IPv6 packet header and any subsequent extension headers include a next header field that will be checked. The value in the next header field identifies the next header in the packet, either an

upper layer protocol header (such as a TCP or UDP header) or an extension header (such as a fragmentation or routing header).

Rule: IPv6 policy is installed but is not enforceable in a stack that is not IPv6 enabled.

Restrictions:

- The RESTRICTED_IPV6_NEXT_HDR attack type applies only to IPv6 packets. The RESTRICTED_IP_OPTIONS and RESTRICTED_IP_PROTOCOL attack types provide analogous function for IPv4 packets.
- You cannot restrict next header values 6 (TCP), 17 (UDP), or 58 (ICMPv6).
- This value is valid only for V1R13 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details.

TCP_QUEUE_SIZE

Indicates that the rule is to detect TCP send, receive, and out-of-order queues that are constrained. A queue can be constrained due to the amount of data on the queue or the age of the data on the queue. A queue size is specified in the rule's conditions. An exclusion list can optionally be specified in the rule's conditions. The TCP_QUEUE_SIZE attack type applies to both IPv4 and IPv6 connections.

Restriction: This value is valid only for V1R13 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details.

OptionPadChk

Indicates whether checking for non-zero IP option pad fields in inbound packets should be enabled or disabled. The default is Enable. For IPv4 packets, the options field is in the IP header and can contain zero filled padding for alignment purposes. For IPv6 packets, a hop-by-hop options extension header or a destination options extension header can include one or more zero filled padding options for alignment purposes.

Restriction: This parameter is valid only for V1R13 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details.

IcmpEmbedPktChk

Indicates whether checking of embedded packets within an inbound ICMP or ICMPv6 error message should be enabled or disabled. The default is Enable.

Restriction: This parameter is valid only for V1R13 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details.

EEXIDTimeout

Indicates the number of XID exchange timeouts that must occur within a 1-minute period in order to be detected as an EE XID flood attack. Valid values are in the range 1- 2 000 000 000. The default value is 100.

Restriction: This parameter is valid only for V1R13 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details.

IfcFloodMinDiscard

Indicates the minimum number of discarded packets that must occur on an interface within a 1 minute period in order to be recognized as an interface flood attack. Valid values are in the range 100 - 4294967295. The default value is 1000.

IfcFloodPercentage

Indicates the percentage of discarded packets for an interface above which an interface flood attack is recognized. Valid values are in the range 5 - 100. The default value is 10.

ProtocolRange

Indicates the restricted protocols for this IDS attack rule.

n m

Integers that specify a protocol range. Valid values for *n* are in the range 0 - 255. If an *m* value is specified, then it must be greater than or equal to *n* and less than 256.

Rule: You must include a blank, a colon (:), or a dash (-) as a delimiter.

ProtocolRangeRef

The name of a globally defined IpProtocolRange statement.

ProtocolGroupRef

The name of a globally defined IpProtocolGroup statement.

RestrictedIpOptionRange

Indicates the restricted IPv4 options for this IDS attack rule.

All

IP options 2 through 255 are restricted. Option 0 (end of option list) and 1 (no-operation) are always allowed and cannot be restricted by policy. This is the default value.

n m

Integers that specify a restricted IP option range. Valid values for *n* are in the range 1 - 255. If an *m* value is specified, then it must be greater than or equal to *n* and less than 256.

Rule: You must include a blank, a colon (:), or a dash (-) as a delimiter.

RestrictedIpOptionRangeRef

The name of a globally defined IpOptionRange statement.

RestrictedIpOptionGroupRef

The name of a globally defined IpOptionGroup statement.

RestrictedIpv6OptionRange

Indicates the restricted IPv6 options for this IDS attack rule.

n m

Integers that specify a restricted option range. Valid values for *n* are in the range 2 - 255. If an *m* value is specified, then it must be greater than or equal to *n* and less than 256.

Rule: You must include a blank, a colon (:), or a dash (-) as a delimiter.

Restriction: This parameter is valid only for V1R13 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details.

RestrictedIpv6OptionRangeRef

The name of a globally defined IpOptionRange statement.

Restriction: This parameter is valid only for V1R13 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details.

RestrictedIpv6OptionGroupRef

The name of a globally defined IpOptionGroup statement.

Restriction: This parameter is valid only for V1R13 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details.

IPv6NextHdrRange

Indicates the restricted IPv6 next header values for this IDS attack rule. The value in the next header field of an IPv6 header or extension header identifies the next header in the packet, either an upper layer protocol (such as TCP or UDP) or an extension header (such as fragmentation or routing).

n m

Integers that specify a restricted IPv6 next header value range. Valid values for *n* are in the range 0 - 255. If an *m* value is specified, then it must be greater than or equal to *n* and less than 256.

Rule: You must include a blank, a colon (:), or a dash (-) as a delimiter.

Restrictions:

- You cannot restrict next header values 6 (TCP), 17 (UDP), or 58 (ICMPv6). They are always allowed.
- This parameter is valid only for V1R13 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details.

IPv6NextHdrRangeRef

The name of a globally defined IPv6NextHdrRange statement.

Restriction: This parameter is valid only for V1R13 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details.

IPv6NextHdrGroupRef

The name of a globally defined IPv6NextHdrGroup statement.

Restriction: This parameter is valid only for V1R13 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details.

LocalPortRange

A list of local ports for this IDS attack rule. Valid values for n are in the range 1 - 65535. If an m value is specified, then it must be greater than or equal to n and less than 65536.

Rule: You must include a blank, a colon (:), or a dash (-) as a delimiter.

Restriction: A LocalPortRange or RemotePortRange of 0 is not allowed.

LocalPortRangeRef

The name of a globally defined PortRange statement to be used for the local port specification.

LocalPortGroupRef

The name of a globally defined PortGroup statement to be used for the local port specification.

RemotePortRange

A list of remote ports for this IDS attack rule. Valid values for n are in the range 1 - 65535. If an m value is specified then it must be greater than or equal to n and less than 65536.

Rule: You must include a blank, a colon (:), or a dash (-) as a delimiter.

Restriction: A LocalPortRange or RemotePortRange of 0 is not allowed.

RemotePortRangeRef

The name of a globally defined PortRange statement to be used for the remote port specification.

RemotePortGroupRef

The name of a globally defined PortGroup statement to be used for the remote port specification.

TcpQueueSize

Indicates the amount of data that must remain on a TCP send, receive, or out-of-order queue for at least thirty seconds before the queue will become constrained. Note that a queue will also become constrained if any amount of data remains on the queue for at least sixty seconds. This parameter is used to select one of a number of abstract queue sizes that map to internally defined limits. For details about queue sizes, see the Attack policies information in [z/OS Communications Server: IP Configuration Guide](#).

- VERY_SHORT
- SHORT (this is the default)
- LONG
- VERY_LONG

Restriction: This parameter is valid only for V1R13 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details.

IDSExclusion

An inline specification of an IDSExclusion statement.

Restriction: This parameter is valid only for V1R13 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details.

IDSExclusionRef

The name of a globally defined IDSExclusion statement.

Restriction: This parameter is valid only for V1R13 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details.

IDSEExclusion statement

Use the IDSEExclusion statement to specify IP addresses, and optionally ports, that are to be excluded when monitoring for certain attacks. For example, you can use an IDSEExclusion statement to exclude a printer connection from being reset by TCP_QUEUE_SIZE attack detection if the printer remains in a persist state for a period of time while out of paper. You can also use the IDSEExclusion statement to exclude a host from the EE_PORT_CHECK attack detection if you know that the host uses ephemeral source ports for Enterprise Extender (EE) traffic.

Restriction: This statement is valid only for V1R13 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details.

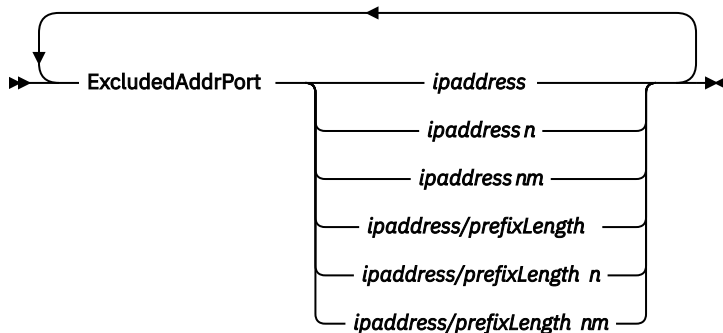

Syntax

Put Braces and Parameters on Separate Lines

IDSEExclusion Parameters

Parameters

name

A string 1 - 32 characters in length that specifies the name of this IDSEExclusion statement.

Rule: If you do not specify this IDSEExclusion statement inline within another statement, you must provide a *name* value. If you do not specify a name for an inline IDSEExclusion statement, a nonpersistent system name is created.

ExcludedAddrPort

Indicates the IP addresses, and optionally ports, that are to be excluded.

ipaddress

A single IPv4 or IPv6 address.

ipaddress n

A single IPv4 or IPv6 address and port. Valid port values for *n* are 0 - 65535. If you specify 0 for *n*, then all ports are excluded.

ipaddress n m

A single IPv4 or IPv6 address and range of ports. Valid port values for *n* are 1 - 65535. The *m* value must be greater than or equal to *n* and less than 65536.

ipaddress/prefixLength

An IPv4 or IPv6 prefix address specification. Valid values for the *prefixLength* value are in the range 0 - 32 for IPv4 addresses and 0 - 128 for IPv6 addresses. An IP address matches this condition if its unmasked bits are identical to the defined unmasked bits.

ipaddress/prefixLength n

An IPv4 or IPv6 prefix address specification and a port. Valid values for the *prefixLength* value are in the range 0 - 32 for IPv4 addresses and 0 - 128 for IPv6 addresses. An IP address matches this condition if its unmasked bits are identical to the defined unmasked bits. Valid port values for *n* are 0 - 65535. If you specify 0 for *n*, all ports are excluded.

ipaddress/prefixLength n m

An IPv4 or IPv6 prefix address specification and a range of ports. Valid values for the *prefixLength* value are in the range 0 - 32 for IPv4 addresses and 0 - 128 for IPv6 addresses. An IP address matches this condition if its unmasked bits are identical to the defined unmasked bits. Valid port values for *n* are 1 - 65535. The *m* value must be greater than or equal to *n* and less than 65536.

Result: Only the first 10,000 ExcludedAddrPort entries are saved and used.

Rule: You can specify a mix of IPv4 and IPv6 addresses in one IDSExclusion statement.

IDSReportSet statement

Use the IDSReportSet statement to specify a report set that you want to associate with actions. A report set can include type of action, statistics interval, logging level, trace data, and trace record size. If a packet meets a policy rule's condition during its validity period, the reports specified in the policy rule's action, such as logging the packet, are produced.

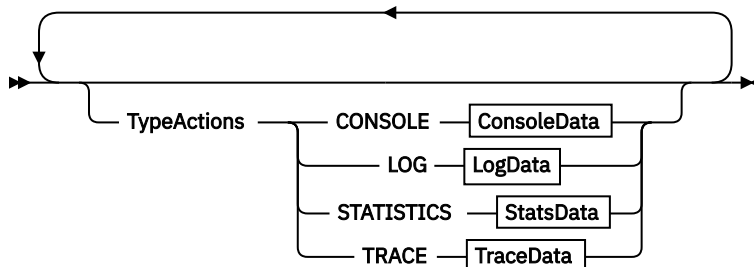

Syntax

Put Braces and Parameters on Separate Lines

IDSReportSet Parameters

ConsoleData

LogData

StatsData

TraceData

Parameters

name

A string 1 - 32 characters in length specifying the name of this IDSReportSet statement.

Rule: If this IDSReportSet statement is not specified inline within another statement, you must provide a *name* value. If a name is not specified for an inline IDSReportSet statement, a nonpersistent system name is created.

TypeActions

Indicates the type of actions to be taken for IDS events. The default value is no TypeActions are defined.

CONSOLE

Report IDS events to the system console.

LOG

Log IDS information to the syslog daemon. Low-level detail records are optionally logged based on the LogDetail value.

STATISTICS

Log statistics to the syslog daemon based on the StatType value.

Result: Statistics are always written to the syslog INFO level.

Rule: The statistics value is applicable when the ConditionType parameter on the IDSRule statement is Attack or TR. For other ConditionType values, the STATISTICS value is ignored.

TRACE

Trace IDS information to the IDS event trace based on the TraceData value. For attack types TCP_QUEUE_SIZE, GLOBAL_TCP_STALL, and EE_XID_FLOOD, the TRACE value is ignored. No tracing is done for those attack types.

MaxEventMessage

Indicates the maximum number of event messages to be displayed on the console during a 5-minute period for an IDS attack type. Valid values are in the range 0 - 4 294 967 295. A value of 0 indicates that attack console messages are not limited. The default value is 5.

Rule: The MaxEventMessage parameter is applicable when the ConditionType parameter in the IDSRule statement is Attack. For other ConditionType values, the MaxEventMessage parameter is ignored.

LogDetail

Indicates whether detailed information is logged to the syslog daemon.

No

Do not log low-level details to the syslog daemon. This is the default value.

Yes

Log low-level details to the syslog daemon when detailed information is available. Low-level details are available when a scan is detected and when a Global TCP Stall attack is detected.

LoggingLevel

Indicates the syslog daemon logging level for logging IDS information. Valid values are in the range 0 - 7. The following values map to syslog daemon priority levels.

0

Emerg/Panic

1

Alert

2

Crit

3

Error

4

Warning

5

Notice

6

Info

7

Debug

The default value is 4.

StatType

Indicates the type of statistics to be gathered.

Normal

Gather all statistics. This is the default value.

Exception

Gather only exception statistics.

StatInterval

Indicates the interval length in minutes for collecting IDS statistics. Valid values are in the range 0 - 4 294 967 295. The default value is 60.

TraceData

Specifies the amount of information written to the IDS event trace.

HEADER

For IPv4 packets, trace the IP and transport headers in the packets. For IPv6 packets, trace the IPv6 header, any extension headers, and the transport header. This is the default value.

FULL

Trace the entire packet.

NONE

No tracing is done.

RECORDSIZE

Trace the amount of data specified by the TraceRecordSize parameter.

TraceRecordSize

Indicates the amount in bytes of packet data to trace, when TraceData is set to RECORDSIZE. Valid values are in the range 0 - 4 294 967 295. The default value is 100.

IDSRule statement

Use the IDSRule statement to enable intrusion detection services based on the ConditionType parameter for an IDSRule statement. See the appropriate condition statement (IDSAttackCondition, IDSScanEventCondition, IDSScanGlobalCondition, or IDSTRCondition) for what is required for each IDS condition type.

Rules:

- An IDSRule statement must contain a reference to a global definition of an IDSAction statement.
- An IDSRule statement must contain one of the following references to a global or inline definition. The condition statement included must match the ConditionType parameter.
 - IDSAttackCondition statement
 - IDSScanEventCondition statement
 - IDSScanGlobalCondition statement
 - IDSTRCondition statement
- The IDS rule can contain a priority, and inline definitions or references to global definitions of the IpTimeCondition statement. An IpTimeCondition specification identifies a time period when the IDS rule is in effect.

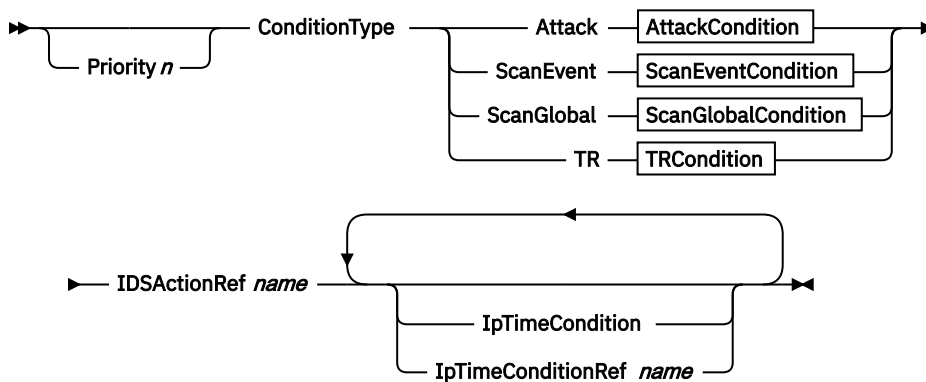

Syntax

►► IDSRule — *name* — Put Braces and Parameters on Separate Lines ►►

Put Braces and Parameters on Separate Lines

IDSRule Parameters

AttackCondition

ScanEventCondition

ScanGlobalCondition

TRCondition

Parameters

name

A string 1 - 32 characters in length that specifies the name of this IDSRule statement.

Priority

An integer value in the range 1 - 2,000,000,000 representing the priority associated with the rule. Only one rule is ever mapped for a given condition type. Rules are searched for a match starting at the highest priority, so if multiple rules can be matched for a given condition type, the rule with the highest priority gets matched first. If multiple rules of the same priority match, the rule that is mapped is difficult to predict.

If this parameter is specified, the computed priority of the rule is the specified value plus 100. If this parameter is not specified, the computed priority of the rule is determined by the number of selection criteria specified, but is always less than 100.

The selection criteria that affect the priority calculation are the following IDSAAttackCondition parameters:

- AttackType
- RestrictedIpOptionRange or RestrictedIPOptionRangeRef
- LocalPortRange or LocalPortRangeRef
- RemotePortRange or RemotePortRangeRef
- ProtocolRange or ProtocolRangeRef
- IPv6NextHdrRange or IPv6NextHdrRangeRef
- RestrictedIpv6OptionRange or RestrictedIpv6OptionRangeRef

The selection criteria that affect the priority calculation are the following IDSScanEventCondition parameters:

- LocalPortRange or LocalPortRangeRef
- LocalHostAddr or LocalHostAddrRef
- Protocol

The selection criteria that affect the priority calculation are the following IDSTRCondition parameters:

- LocalPortRange or LocalPortRangeRef
- LocalHostAddr or LocalHostAddrRef
- Protocol

Guideline: When setting the priority for multiple rules, you should not set the priority as a sequential value, for example 2, 3, 4, and 5. Instead, set the priority so there is room to change the priority, such that the rule would be preferred over another rule, without duplicating a priority. For example, you could configure the priorities as 20, 30, 40, and 50.

ConditionType

Attack

Indicates that this is an Attack IDS rule. This rule is for attack detection, reporting, and prevention.

ScanEvent

Indicates that this is a scan event IDS rule. This rule defines the type of inbound traffic to be monitored by scan detection. A scan global IDS rule is also required for scan detection activation.

ScanGlobal

Indicates that this is a scan global IDS rule. This rule is for global definitions used for scan detection such as fast scan and slow scan conditions. It also defines the type of reporting used when a scan is detected.

TR

Indicates that this is a traffic regulation IDS rule. This rule is for traffic regulation for TCP connections and UDP receive queues.

Result: An IDSRule should include one ConditionType parameter. If more than one is present the last one is used.

IDSAttackCondition

An inline specification of an IDSAttackCondition statement.

IDSAttackConditionRef

The name of a globally defined IDSAttackCondition statement.

IDSScanEventCondition

An inline specification of an IDSScanEventCondition statement.

IDSScanEventConditionRef

The name of a globally defined IDSScanEventCondition statement.

IDSScanGlobalCondition

An inline specification of an IDSScanGlobalCondition statement.

Rule: Only one scan global IDS rule can be configured for a stack.

IDSScanGlobalConditionRef

The name of a globally defined IDSScanGlobalCondition statement.

Rule: Only one scan global IDS rule can be configured for a stack.

IDSTRCondition

An inline specification of an IDSTRCondition statement.

IDSTRConditionRef

The name of a globally defined IDSTRCondition statement.

IDSActionRef

The name of a globally defined IDSAction statement.

IpTimeCondition

An inline specification of an IpTimeCondition statement. There is a limit of 25 IpTimeCondition specifications on the IDSRule.

IpTimeConditionRef

The name of a globally defined IpTimeCondition statement. There is a limit of 25 IpTimeCondition references on the IDSRule.

IDSScanEventCondition statement

Use the IDSScanEventCondition statement to define the conditions that scan processing monitors. These policies are searched by this ScanEvent condition type and a protocol condition of ICMP, ICMPv6, TCP, or UDP. For protocols TCP and UDP, the policy search also includes local destination port and bound IP address.

The IDSScanEventCondition statements can contain a definition of LocalHostAddr, or this value can be specified with references to global definitions of IpAddr, IpAddrSet, or IpAddrGroup statements.

The IDSScanEventCondition statements can contain an inline definition of IDSScanExclusion, or this value can be specified with references to global definitions of IDSScanExclusion statements.

The IDSScanEventCondition statements can contain a definition of LocalPortRange or this value can be specified with references to global definitions of PortRange or PortGroup statements.

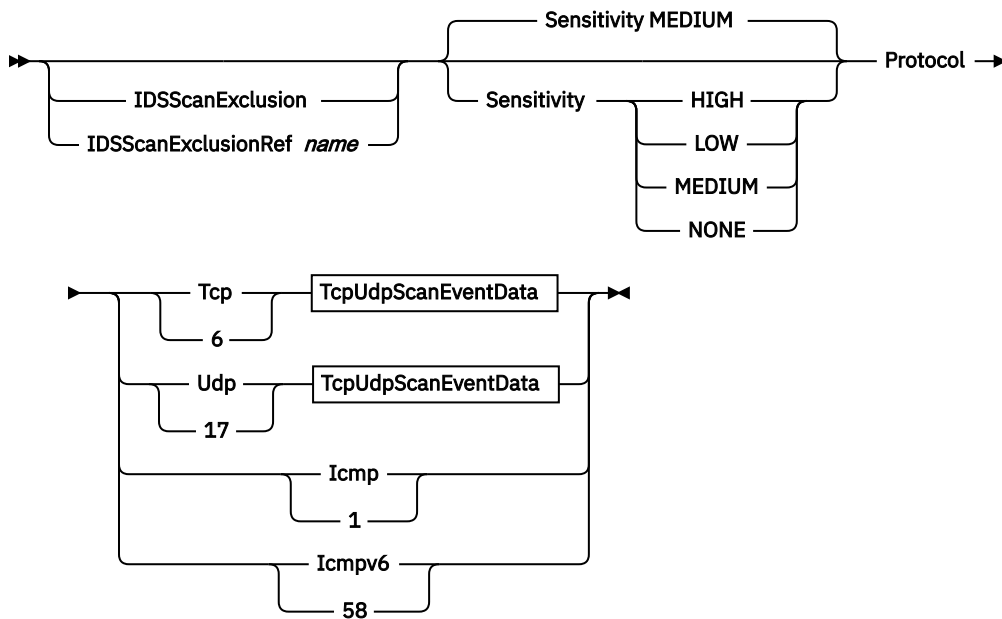

Syntax

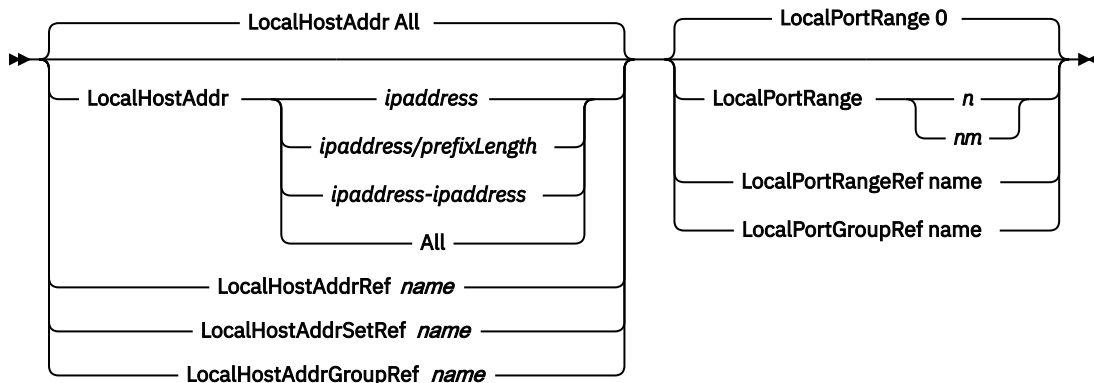

Put Braces and Parameters on Separate Lines

IDSScanEventCondition Parameters

TcpUdpScanEventData

Parameters

name

A string 1 -32 characters in length specifying the name of this IDSScanEventCondition statement.

Rule: If this IDSScanEventCondition statement is not specified inline within another statement, a *name* value must be provided. If a name is not specified for an inline IDSScanEventCondition statement, a nonpersistent system name is created.

IDSScanExclusion

An inline specification of an IDSScanExclusion statement.

IDSScanExclusionRef

The name of a globally defined IDSScanExclusion statement.

Sensitivity

Indicates the sensitivity of events monitored for fast and slow scan detection. Events that are monitored can be classified as normal, possibly suspicious, or very suspicious. This parameter indicates which of these types of events should be counted for scan detection.

None

Indicates that no events are counted.

High

Indicates that all event types are counted.

Medium

Indicates that possibly suspicious and very suspicious events are counted. This is the default value.

Low

Indicates that only very suspicious events are counted.

Protocol

Indicates the protocol name or number for this IDS ScanEvent rule.

Restriction: The values Icmpv6 and 58 are valid only for V1R13 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details.

LocalHostAddr

A local host IP address for this IDS ScanEvent rule. The specified IP address is used to match applications that either explicitly bind to this address, or that have the IP address assigned by the TCP/IP stack. All indicates that any local IP address matches this rule. The default value is All.

ipaddress

A single IPv4 or IPv6 address.

ipaddress/prefixLength

The number of unmasked leading bits in the *ipaddress* value. The *prefixLength* value can be in the range 0 - 32 for IPv4 addresses and in the range 0 - 128 for IPv6 addresses. An IP address matches this condition if its unmasked bits are identical to the defined unmasked bits.

ipaddress-ipaddress

A range of IPv4 or IPv6 addresses.

Tip: All includes all IPv4 and IPv6 addresses. If you want to include only IPv4 addresses specify LocalHostAddr 0.0.0.0/0. If you want to include only IPv6 addresses specify LocalHostAddr ::0/0.

Result: When centralized policy is used, All includes all IPv4 and IPv6 addresses regardless of the release level of the policy server.

Rule: An IPv6 address specified for LocalHostAddr cannot be an IPv4-mapped IPv6 address (in hexadecimal or dotted decimal format) or an IPv6 address with the reserved prefix ::/96.

LocalHostAddrRef

The name of a globally defined IpAddr statement to be used for the local IP address specification.

LocalHostAddrSetRef

The name of a globally defined IpAddrSet statement to be used for the local IP address prefix or range specification.

LocalHostAddrGroupRef

The name of a globally defined IpAddrGroup statement to be used for the local IP address specification.

LocalPortRange

A local port for this IDS scan event rule. Valid values for n are 0 - 65535. If 0 is specified for n then the rule applies to any local port. If n is specified as the beginning value for a range, then 0 is not a valid value. If an m value is specified, then it must be greater than or equal to n and less than 65536. The default value is 0.

Rule: You must include a blank, a colon (:), or a dash (-) as a delimiter.

LocalPortRangeRef

The name of a globally defined PortRange statement to be used for the local port specification

LocalPortGroupRef

The name of a globally defined PortGroup statement to be used for the local port specification.

IDSScanExclusion statement

Use the IDSScanExclusion statement to specify IP addresses and optionally, ports, that are to be excluded when monitoring for scans. For example, responses from name servers might appear to be scans, unless the name servers are excluded using this statement.

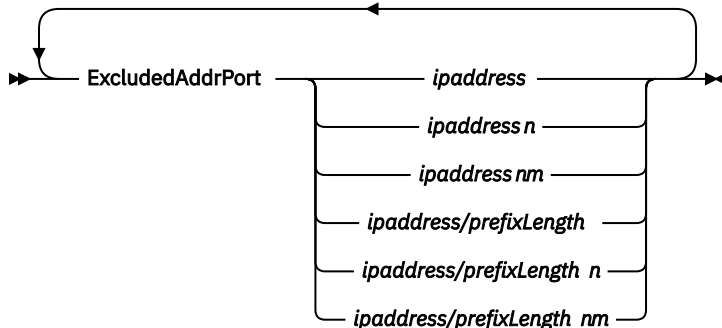

Syntax

Put Braces and Parameters on Separate Lines

IDSScanExclusion Parameters

Parameters

name

A string 1-32 characters in length specifying the name of this IDSScanExclusion statement.

Rule: If this IDSScanExclusion statement is not specified inline within another statement, a *name* value must be provided. If a name is not specified for an inline IDSScanExclusion statement, a nonpersistent system name is created.

ExcludedAddrPort

Indicates the IP addresses and optionally ports that are to be excluded when monitoring for scans.

ipaddress

A single IPv4 or IPv6 address.

ipaddress n

A single IPv4 or IPv6 address and port. Valid port values for *n* are 0 - 65535. If 0 is specified for *n*, then all ports are excluded.

ipaddress n m

A single IPv4 or IPv6 address and range of ports. Valid port values for *n* are 1 - 65535. The *m* value must be greater than or equal to *n* and less than 65536.

ipaddress/prefixLength

An IPv4 or IPv6 prefix address specification. Valid values for the *prefixLength* value are in the range 0 - 32 for IPv4 addresses and 0 - 128 for IPv6 addresses. An IP address matches this condition if its unmasked bits are identical to the defined unmasked bits.

ipaddress/prefixLength n

An IPv4 or IPv6 prefix address specification and a port. Valid values for the *prefixLength* value are in the range 0 - 32 for IPv4 addresses and 0 - 128 for IPv6 addresses. An IP address matches this condition if its unmasked bits are identical to the defined unmasked bits. Valid port values for *n* are 0 - 65535. If 0 is specified for *n*, all ports are excluded.

ipaddress/prefixLength n m

An IPv4 or IPv6 prefix address specification and a range of ports. Valid values for the *prefixLength* value are in the range 0 - 32 for IPv4 addresses and 0 - 128 for IPv6 addresses. An IP address matches this condition if its unmasked bits are identical to the defined unmasked bits. Valid port values for *n* are 1 - 65535. The *m* value must be greater than or equal to *n* and less than 65536.

Result: Only the first 10000 ExcludedAddrPort entries are saved and used.

Rule: You can specify a mix of IPv4 and IPv6 addresses within one IDSScanExclusion statement.

IDSScanGlobalCondition statement

Use the IDSScanGlobalCondition statement for global scan detection and reporting. The action defines the reporting and tracing actions to take when a scan event is detected.

Rule: You can configure only one IDSScanGlobalCondition statement with an IDSScanGlobalCondition parameter. If you configure multiple scan global rules with different names, the first instance is used and all others are discarded as errors. If you configure multiple scan global rules with the same name, the last instance is used.

Syntax

Put Braces and Parameters on Separate Lines

IDSScanGlobalCondition Parameters

Parameters

name

A string 1 -32 characters in length specifying the name of this IDSScanGlobalCondition statement.

Rule: If this IDSScanGlobalCondition statement is not specified inline within another statement, a *name* value must be provided. If a name is not specified for an inline IDSScanGlobalCondition statement, a nonpersistent system name is created.

FSInterval

Indicates the interval in minutes for monitoring for fast scans. Valid values are in the range 1 - 1440. The default value is 1.

FSThreshold

Indicates the fast scanning threshold. A fast scan is detected if the number of events from a single source meets or exceeds this threshold and occur within the interval defined by the FSInterval value. Valid values are in the range 1 - 64. The default value is 5.

SSInterval

Indicates the interval in minutes for monitoring for slow scans. Valid values are in the range 0 - 1440. The default value is 120. The value specified must be greater than the value specified for the FSInterval parameter. However, a value of 0 can be specified to indicate that no slow scan processing should be performed.

SSThreshold

Indicates the slow scanning threshold. A slow scan is detected if the number of events from a single source meets or exceeds this threshold and occurs within the interval defined by the SSInterval value. Valid values are in the range 0 - 64. The default value is 10. The value specified must be greater than the value specified for the FSThreshold parameter. However, a value of 0 can be specified to indicate that no slow scan processing should be performed.

IDSTRCondition statement

Use the IDSTRCondition statement for traffic regulation for TCP connections and UDP receive queues. TCP rules are mapped when a local application does a listen on a socket or when an inbound connection handshake completes. UDP rules are mapped when an inbound packet arrives at a local bound socket. UDP TR policy supersedes the TCPIP PROFILE setting of UDPQUEUELIMIT for covered ports.

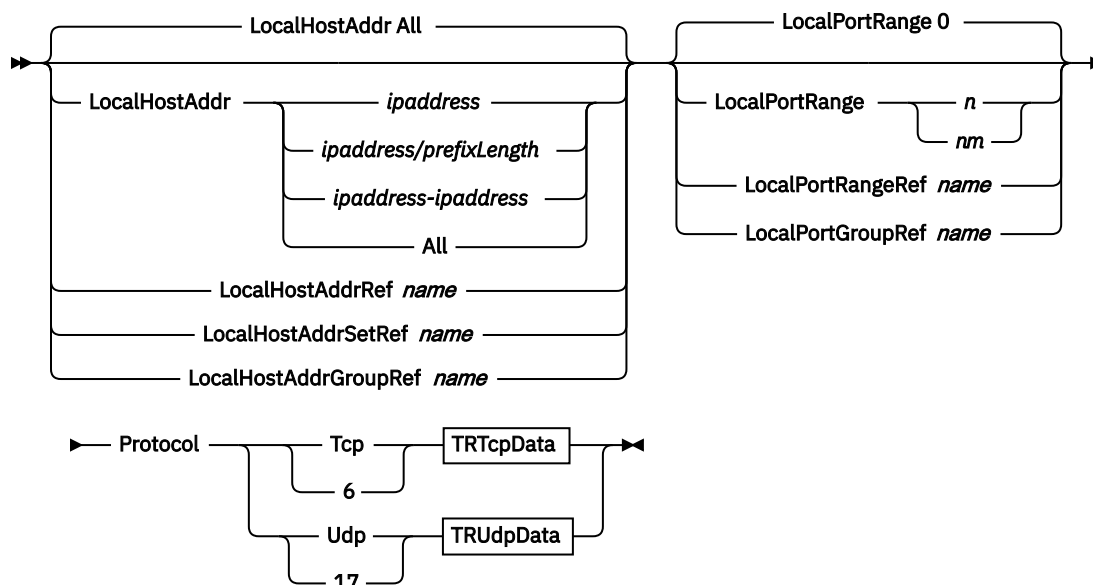

Syntax

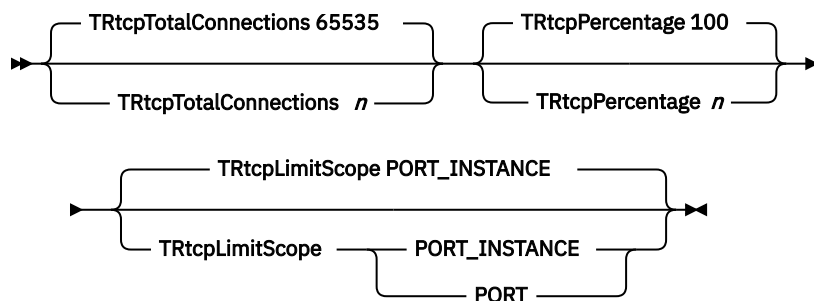

Put Braces and Parameters on Separate Lines

IDSTRCondition Parameters

TRtcpData

TRUdpData

Parameters

name

A string 1 - 32 characters in length specifying the name of this IDSTRCondition statement.

Rule: If this IDSTRCondition statement is not specified inline within another statement, a *name* value must be provided. If a name is not specified for an inline IDSTRCondition statement, a nonpersistent system name is created.

LocalHostAddr

A local IP host address for this IDS TR rule. The specified IP address is used to match applications that either explicitly bind to this address, or that have the IP address assigned by the TCP/IP stack. All indicates that any local IP address matches this rule. The default value is All.

ipaddress

A single IPv4 or IPv6 address.

ipaddress/prefixLength

An IPv4 or IPv6 prefix address specification. The number of unmasked leading bits in *ipaddress*. The *prefixLength* can be in the range 0 - 32 for IPv4 addresses or 0 - 128 for IPv6 addresses. An IP address matches this condition if its unmasked bits are identical to the defined unmasked bits.

ipaddress- ipaddress

A range of IPv4 or IPv6 addresses.

Tip: The value ALL includes all IPv4 and IPv6 addresses. If you want to include only IPv4 addresses specify LocalHostAddr 0.0.0.0/0. If you want to include only IPv6 addresses specify LocalHostAddr ::0/0.

Result: When centralized policy is used, All includes all IPv4 and IPv6 addresses regardless of the release level of the policy server.

Rules:

- The LocalHostAddr parameter cannot be specified if TRtcpLimitScope PORT was specified.
- An IPv6 address specified for LocalHostAddr cannot be an IPv4-mapped IPv6 address (in hexadecimal or dotted decimal format) or an IPv6 address with the reserved prefix ::/96.

LocalHostAddrRef

The name of a globally defined IpAddr statement to be used for the local IP address specification.

LocalHostAddrSetRef

The name of a globally defined IpAddrSet statement to be used for the local IP address prefix or range specification.

LocalHostAddrGroupRef

The name of a globally defined IpAddrGroup statement to be used for the local IP address specification.

LocalPortRange

Indicates the local ports for this IDS TR rule. Valid values for *n* are 0 - 65535. If 0 is specified for *n*, the rule applies to any local port. If *n* is specified as the beginning value for a range, 0 is not a valid value. If an *m* value is specified, it must be greater than or equal to *n* and less than 65536. The default value is 0.

Rule: You must include a blank, a colon (:), or a dash (-) as a delimiter.

LocalPortRangeRef

The name of a globally defined PortRange statement to be used for the local port specification.

LocalPortGroupRef

The name of a globally defined PortGroup statement to be used for the local port specification.

Protocol

Indicates the protocol name or number for this IDS TR rule.

TRtcpTotalConnections

Indicates the size of the total connection pool for IDS TCP traffic regulation functions. Valid values are in the range 0 - 65535. The default value is 65535.

TRtcpPercentage

Indicates the percentage of connections that can be used by a single host. The percentage is applied to the number of available connections in the pool established by TRtcpTotalConnections. Valid values are in the range 0 - 100. The default value is 100.

TRtcpLimitScope

Indicates the scope of TCP traffic regulation.

PORT_INSTANCE

Indicates that traffic regulation parameters apply to each socket that is bound to the target port individually. This is the default value.

PORT

Indicates that traffic regulation parameters apply to the aggregate of all sockets that are bound to the target port.

Rule: The LocalHostAddr parameter cannot be specified if TRtcpLimitScope PORT was specified.

TRudpQueueSize

Indicates the size of the port backlog queue. This parameter is used to select one of a number of abstract queue sizes that map to internally defined limits. For details about queue sizes, see the [TR UDP information](#) in [z/OS Communications Server: IP Configuration Guide](#).

- LONG
- SHORT
- VERY_LONG (this is the default)
- VERY_SHORT

IPSec policy statements

This topic contains information about the following IPSec policy statements:

- [“IpDataOffer statement” on page 989](#)
- [“IpDynVpnAction statement” on page 994](#)
- [“IpFilterGroup statement” on page 1001](#)
- [“IpFilterPolicy statement” on page 1001](#)
- [“IpFilterRule statement” on page 1004](#)
- [“IpGenericFilterAction statement” on page 1008](#)
- [“IpLocalStartAction statement” on page 1010](#)
- [“IpManVpnAction statement” on page 1016](#)
- [“IpService statement” on page 1023](#)

- [“RemoteSecurityEndpoint statement” on page 1063](#)

The IPSec sample files are: /usr/lpp/tcpip/samples/pagent_CommonIPSec.conf /usr/lpp/tcpip/samples/pagent_IPSec.conf

Tip: The terms phase 1 and phase 2 refer to different types of security associations (SAs) that the z/OS IKE daemon can negotiate with its peers. Although the specific terminology for these types of security associations differs between the IKE version 1 and IKE version 2 protocols, the terms phase 1 and phase 2 refers to both versions, as shown in [Table 81 on page 988](#).

Table 81. IKE terminology: phase 1 and phase 2	
Term	Usage in regard to IKE protocol version
Phase 1 security association (SA)	Refers to IKE version 1 phase 1 SAs as well as IKE version 2 IKE SAs. When a specific version is intended, that version is identified in this document.

Table 81. IKE terminology: phase 1 and phase 2 (continued)

Term	Usage in regard to IKE protocol version
Phase 2 security association (SA)	Refers to IKE version 1 phase 2 SAs as well as IKE version 2 child SAs. When a specific version is intended, that version is identified in this document.

IpDataOffer statement

Use the IpDataOffer statement to define a data offer for a dynamic VPN. An IP data offer indicates one acceptable way to protect data sent through a dynamic VPN. An IpDataOffer statement can be referenced by an IpDynVpnAction statement.

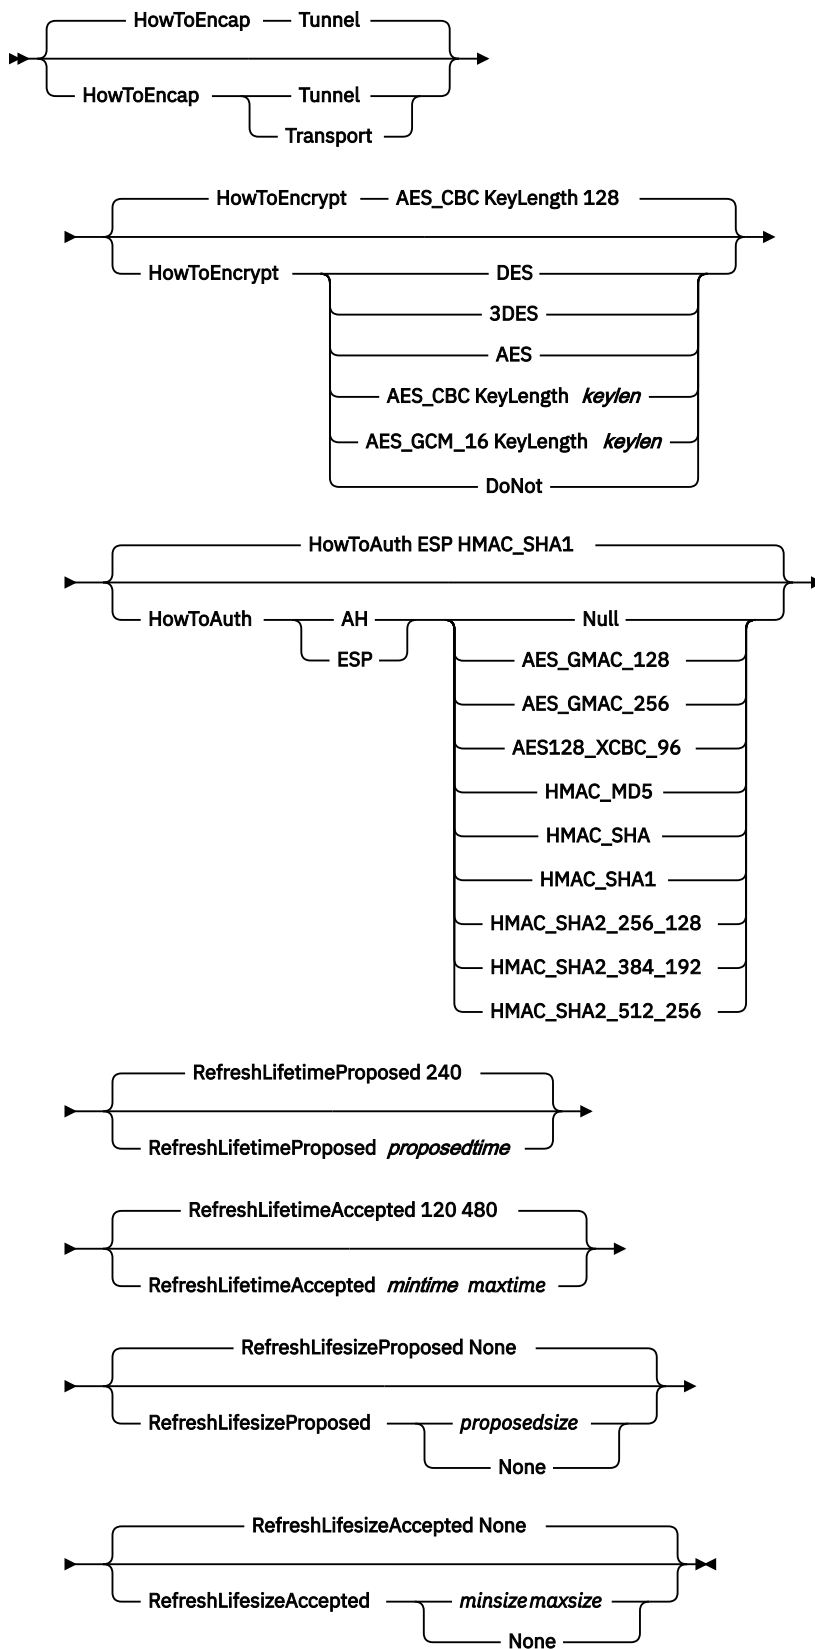

Syntax

Put Braces and Parameters on Separate Lines

IpDataOffer Parameters

Parameters

name

A string 1 - 32 characters in length specifying the name of this `IpDataOffer` statement.

Rule: If this IpDataOffer statement is not specified inline within another statement, a *name* value must be provided.

If a name is not specified for an inline IpDataOffer statement, a nonpersistent system name is created.

HowToEncap

The encapsulation mode of the dynamic VPN's security associations when IKE version 1 is used. The default is tunnel mode.

Tunnel

Specifies that the security association operates in tunnel mode, which protects the entire IP packet. This mode must be used for a secure tunnel between two security gateways or between a security gateway and a remote system. One or both of the communication endpoints can be on different systems than the security endpoints.

Transport

Specifies that the security association operates in transport mode, which protects only the transport-layer headers and data (for example, TCP or UDP packet) inside an IP packet. This mode can be used only when the endpoints of the security association are the two communicating systems (that is, neither system acts as a gateway).

Restriction: HowToEncap is ignored for dynamic VPNs that are negotiated using IKE version 2. The encapsulation mode for IKE version 2 security associations is determined by the HowToEncapIkev2 parameter on the IPDynVpnAction statement.

HowToEncrypt

Encryption is done using the ESP protocol. Specify the encryption algorithm used to provide data confidentiality. The default is **AES_CBC KeyLength 128**.

DES

DES encryption is used with a 56-bit key and a 64-bit initialization vector.

Restriction: DES is not accepted when the TCP/IP stack is configured for FIPS 140 mode on the IpFilterPolicy statement.

3DES

Triple DES runs the DES encryption algorithm three times and uses 192-bits, including 24 parity bits.

Rule: If 3DES is specified but is not supported by the system, the Policy Agent fails the policy.

AES

Deprecated and treated as a synonym for AES_CBC KeyLength 128.

Rule: If AES is specified but AES encryption in CBC mode is not supported by this TCP/IP stack, Policy Agent fails the policy.

AES_CBC

The Advanced Encryption Standard (AES) algorithm is used in Cipher Block Chaining (CBC) mode.

Rules:

- The key length is measured in bits, and a *keylen* of either 128 or 256 must be specified.
- If AES_CBC is specified but AES encryption in CBC mode is not supported by this TCP/IP stack, Policy Agent fails the policy.

Restriction: This value is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details

AES_GCM_16

The AES algorithm is used in Galois Counter Mode (GCM) and with a 16-byte Integrity Check Value (ICV). Galois Counter Mode is a combined-mode algorithm that performs both encryption and authentication simultaneously.

Rules:

- The key length is measured in bits, and a *keylen* of either 128 or 256 must be specified.
- HowToAuth ESP NULL must be specified if AES_GCM_16 is specified.
- If AES_GCM_16 is specified but AES encryption in Galois Counter Mode is not supported by this TCP/IP stack, Policy Agent fails the policy.

Restriction: This value is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details.

DoNot

No encryption is used.

If the HowToEncrypt value **DoNot** is specified with a HowToAuth **ESP** value, the ESP header is present, but the payload is not encrypted (ESP_NULL).

HowToAuth

The desired authentication policy indicating which protocol and which algorithm to use when authenticating data. The default is ESP HMAC_SHA1.

AH

Carry authentication in AH headers.

ESP

Carry authentication in ESP headers.

AES_GMAC_128

Use the AES_GMAC algorithm to encode authentication data in either AH or ESP headers, with 128-bit keys. AES_GMAC functions as a combined-mode algorithm that provides authentication without encryption.

Rule: AES_GMAC_128 may be specified only in combination with HowToEncrypt DoNot.

Tip: If you want a combined-mode algorithm that provides both authentication and encryption, choose HowToEncrypt AES_GCM_16.

Restriction: This value is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details.

AES_GMAC_256

Use the AES_GMAC algorithm to encode authentication data in either AH or ESP headers, with 256-bit keys. AES_GMAC functions as a combined-mode algorithm that provides authentication without encryption.

Rule: AES_GMAC_256 may be specified only in combination with HowToEncrypt DoNot.

Tip: If you want a combined-mode algorithm that provides both authentication and encryption, choose HowToEncrypt AES_GCM_16.

Restriction: This value is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details.

AES128_XCBC_96

Use the AES128_XCBC algorithm to encode authentication data in either AH or ESP headers, with 128-bit keys and hash truncation to 96 bits.

Restriction: AES128_XCBC_96 is not accepted when the TCP/IP stack is configured for FIPS 140 mode on the IpFilterPolicy statement.

Restriction: This value is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details.

HMAC_MD5

Use the HMAC_MD5 algorithm to encode authentication data in either AH or ESP headers.

Restriction: HMAC_MD5 is not accepted when the TCP/IP stack is configured for FIPS 140 mode on the IpFilterPolicy statement.

HMAC_SHA

Deprecated and treated as a synonym for HMAC_SHA1.

HMAC_SHA1

Use the HMAC_SHA1 algorithm to encode authentication data in either AH or ESP headers.

Restriction: This value is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details

HMAC_SHA2_256_128

Use the HMAC_SHA2_256 algorithm to encode authentication data in either AH or ESP headers, with 256-bit keys and hash truncation to 128 bits.

Restriction: This value is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details

HMAC_SHA2_384_192

Use the HMAC_SHA2_384 algorithm to encode authentication data in either AH or ESP headers, with 384-bit keys and hash truncation to 192 bits.

Restriction: This value is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details

HMAC_SHA2_512_256

Use the HMAC_SHA2_512 algorithm to encode authentication data in either AH or ESP headers, with 512-bit keys and hash truncation to 256 bits.

Restriction: This value is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details

Null

Use no authentication.

Rule: NULL may only be specified with HowToAuth ESP and only in combination with HowToEncrypt AES_GCM_16.

Restriction: This value is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details

Restriction: HowToAuth AH may be specified in combination with HowToEncrypt only if the security association is negotiated using IKE version 1 because IKE version 2 does not permit the combining of AH and ESP. If this combination is specified for an IKE version 2 security association, the IPDataOffer is ignored.

RefreshLifetimeProposed

The security association lifetime in minutes. For IKE version 1, this value is proposed when acting as the initiator of a key exchange negotiation. For IKE version 2, this value determines the refresh lifetime. The default is 240.

proposedtime

The lifetime proposed (for IKE version 1) or used (for IKE version 2) for the phase 2 tunnel. Valid values are in the range 1 - 9 999. The proposed lifetime value should be within the range specified by the RefreshLifetimeAccepted parameter.

Tip: For IKE version 2 security associations, if the RefreshLifetimeProposed value is longer than that of the ReauthInterval on the associated KeyExchangeAction, the reauthentication will usually occur before the re-keying occurs.

RefreshLifetimeAccepted

A range of acceptable security association lifetimes in minutes. This range is accepted when acting as the responder of IKE version 1 key exchange negotiation. The default is 120 480.

mintime

The minimum lifetime that can be accepted.

maxtime

The maximum lifetime that can be accepted. This value must be \geq to the *mintime* value.

Valid values for each option are in the range 1 - 9 999.

Restriction: This parameter is ignored for IKE version 2 SAs.

RefreshLifesizeProposed

The security association lifesize in Kbytes. If a *proposedsize* value is specified, then this value is proposed when acting as the IKE version 1 initiator of a key exchange negotiation. For IKE version 2, this value determines the refresh lifesize. If **None** is specified, then no lifesize is proposed for IKE version 1 or used for IKE version 2. The default is **None**.

proposedsize

The proposed lifesize for the negotiation. Valid values are in the range 1 - 4 194 300.

The proposed *lifesize* value should be within the range specified by RefreshLifesizeAccepted parameter, if that parameter is not specified as **None**.

None

No lifesize should be proposed for IKE version 1 or used for IKE version 2. If this parameter is specified as **None**, then RefreshLifesizeAccepted parameter should also be specified as **None**.

RefreshLifesizeAccepted

The security association lifesize in Kbytes. If *minsize* and *maxsize* values are specified, then this range is accepted when acting as the responder of an IKE version 1 key exchange negotiation. If **None** is specified, then no *lifesize* is accepted when acting as the responder of a key exchange negotiation. The default is **None**.

Result: The IKED accepts a proposed *lifesize* greater than 4 194 300, only if a *maxsize* of exactly 4 194 300 is specified. If the IKED accepts a *lifesize* greater than 4 194 300, it assigns an actual lifesize of 4 194 300 to the security association.

minsize

The minimum *lifesize* that can be accepted.

maxsize

The maximum *lifesize* that can be accepted. This value must be \geq to the *minsize* value.

None

No *lifesize* is accepted. If this parameter is specified as **None**, then RefreshLifesizeProposed value should also be specified as **None**.

Valid values for the *minsize* and *maxsize* options are 1 - 4 194 300.

Restriction: This parameter is ignored for IKE version 2 SAs.

Rules:

- The IpDataOffer statement allows for 0 - 1 authentication proposals and 0 - 1 encryption proposals. Multiple authentication proposals or multiple encryption proposals cannot be specified in the same IpDataOffer statement.
- To propose authentication using only the ESP header, specify **HowToEncrypt DoNot** and **HowToAuth ESP xxx** where xxx represents a valid authentication algorithm.. The ESP header is present, but the payload is not encrypted.

Result: If both HowToAuth AH and HowToEncrypt are specified when using IKE version 1, then for outbound traffic the encryption proposal is always applied before the authentication proposal (IKE version 2 does not permit combining AH and ESP). For example, if **HowToEncrypt DES** and **HowToAuth AH HMAC_SHA** are specified, this is understood to mean that data is first encrypted and the results are then authenticated and carried in an AH header.

IpDynVpnAction statement

Use the IpDynVpnAction statement to indicate how selected data traffic between two security endpoints should be protected utilizing dynamically established security associations. An IpDynVpnAction statement contains inline definitions or references to IpDataOffer statements, or both.

Dynamically established security associations are created by the IKE daemon and are used to protect data sent through a dynamic VPN. Dynamic VPNs can be established in the following ways:

- Automatically established when the TCP/IP stack comes up or when the IKE daemon comes up, or both. This is known as an autoactivation.
- Established with an **ipsec** command. This is known as a command-line activation.
- Automatically established with an outbound IP packet. This is known as an on-demand activation.
- Established with a phase 2 IKE negotiation initiated by a remote security endpoint. This is known as a remote activation.

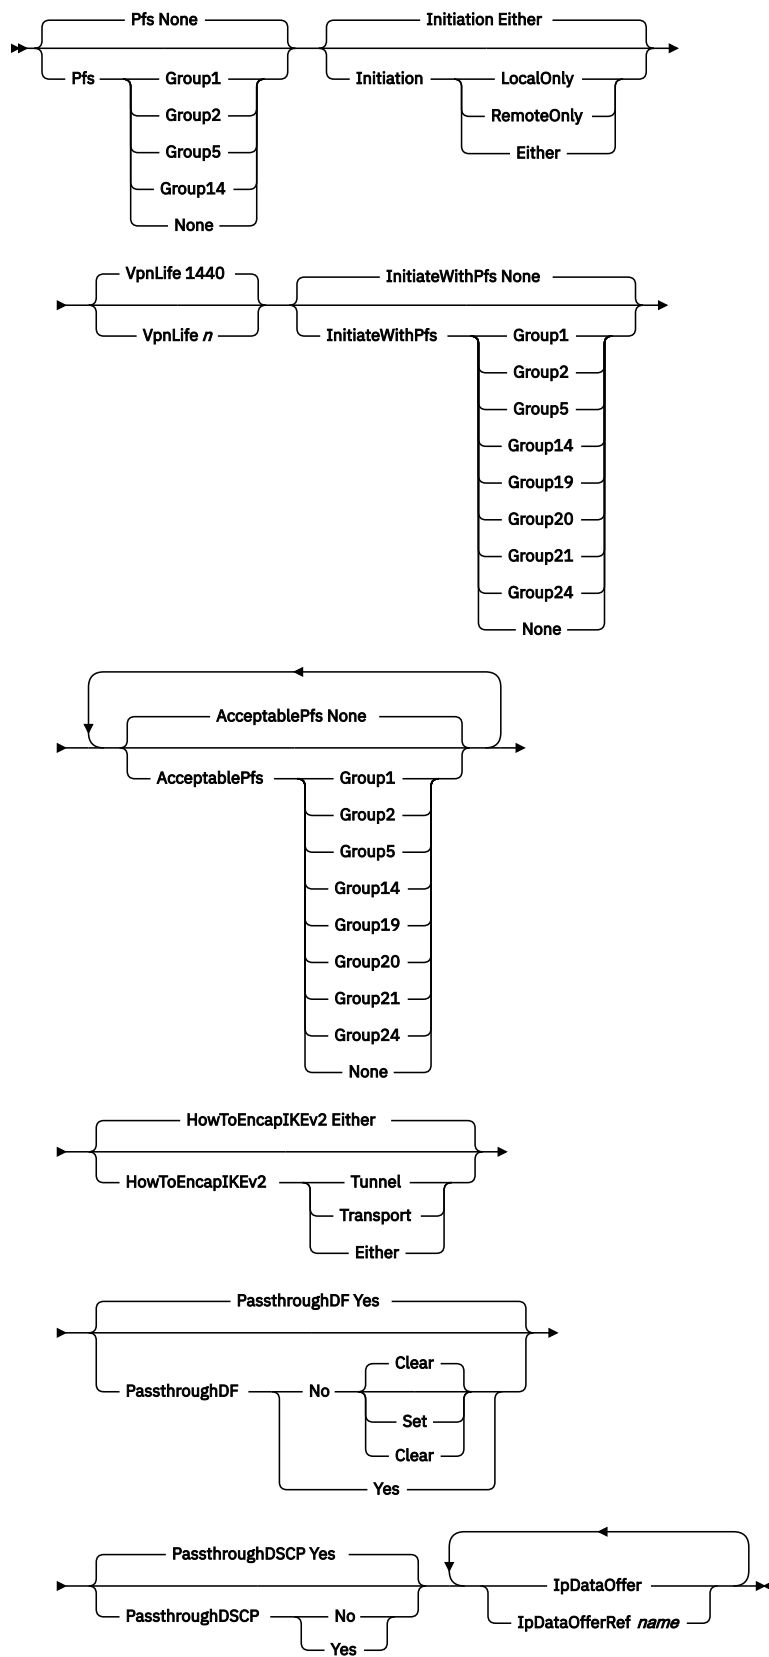

Syntax

➤➤ IpDynVpnAction — *name* — Put Braces and Parameters on Separate Lines ➤➤

Put Braces and Parameters on Separate Lines

IpDynVpnAction Parameters

Parameters

name

A string 1 - 32 characters in length specifying the name of this IpDynVpnAction statement. The name cannot start with a dash (-) or contain any commas (,).

Pfs

Specifies whether perfect forward secrecy (PFS) is used when negotiating the security association, and if so, what Diffie-Hellman group is used. The default is None.

None

Do not use perfect forward secrecy.

Group1

Modular exponentiation group with a 768-bit modulus.

Restriction: Group 1 is not accepted when the TCP/IP stack is configured for FIPS 140 mode on the IpFilterPolicy statement.

Group2

Modular exponentiation group with a 1024-bit modulus.

Restriction: Group 2 is not accepted when the TCP/IP stack is configured for FIPS 140 mode on the IpFilterPolicy statement.

Group5

Modular exponentiation group with a 1536-bit modulus.

Restriction: Group 5 is not accepted when the TCP/IP stack is configured for FIPS 140 mode on the IpFilterPolicy statement.

Group14

Modular exponentiation group with a 2048-bit modulus.

Guideline: If you are using encryption or authentication algorithms with a 128-bit key, use Diffie-Hellman groups 5,14,19,20, or 24. If you are using encryption or authentication algorithms with a key length of 256 bits or greater, use Diffie-Hellman group 21.

Rule: Pfs is deprecated. Use InitiateWithPfs and AcceptablePfs parameters instead. If you use Pfs, then InitiateWithPfs and AcceptablePfs are set to the Pfs value.

Restriction: Do not use the Pfs parameter in conjunction with the InitiateWithPfs or AcceptablePfs parameters.

Initiation

Specifies which system can initiate the security associations for this dynamic tunnel. The default is **Either**.

LocalOnly

Specifies that this system must initiate the negotiation.

RemoteOnly

Specifies that another system must initiate the negotiation.

Either

Specifies that this system can either initiate a negotiation or respond to a negotiation initiated by another system.

VpnLife

Maximum length of time that phase 2 SAs should continue to be refreshed, in minutes. The VpnLife parameter is set for a dynamic VPN tunnel when the first SA is established for the tunnel. The VpnLife value for a dynamic VPN tunnel can be changed by deactivating the tunnel, changing the configured VpnLife value, and then activating the tunnel. Valid values are in the range 0 - 525 600 minutes. Specifying a value of 0 means that the maximum lifetime is infinite. The default is 1440 minutes. In any case, regardless of the VpnLife setting, SAs that are configured with AllowOnDemand Yes may cease to be refreshed if they have not protected any network traffic during their previous refresh interval.

AcceptablePfs

Specifies acceptable Diffie-Hellman groups to use for perfect forward secrecy (PFS). The default is **None**.

None

Do not use perfect forward secrecy.

Group1

Modular exponentiation group with a 768-bit modulus.

Restriction: Group 1 is not accepted when the TCP/IP stack is configured for FIPS 140 mode on the IpFilterPolicy statement.

Group2

Modular exponentiation group with a 1024-bit modulus.

Restriction: Group 2 is not accepted when the TCP/IP stack is configured for FIPS 140 mode on the IpFilterPolicy statement.

Group5

Modular exponentiation group with a 1536-bit modulus.

Restriction: Group 5 is not accepted when the TCP/IP stack is configured for FIPS 140 mode on the IpFilterPolicy statement.

Group14

Use modular exponentiation group with a 2048-bit modulus.

Group19

Random 256-bit elliptic curve group.

Restriction: This value is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details

Group20

Random 384-bit elliptic curve group.

Restriction: This value is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details

Group21

Random 521-bit elliptic curve group.

Restriction: This value is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details

Group24

Modular exponentiation group with a 2048-bit modulus and 256-bit prime order subgroup.

Restriction: This value is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details

Result: For negotiations using IKE version 1, the AcceptablePfs list is used when the z/OS IKE daemon is the responder for a security association. For negotiations using IKE version 2, the AcceptablePfs list is used in both initiator and responder modes.

Guideline: If you are using encryption or authentication algorithms with a 128-bit key, use Diffie-Hellman groups 5,14,19,20, or 24. If you are using encryption or authentication algorithms with a key length of 256 bits or greater, use Diffie-Hellman group 21.

Rule: The InitiateWithPfs Diffie-Hellman group must be specified as one of the values in the AcceptablePfsList parameter.

Restriction: Do not use the Pfs parameter in conjunction with the InitiateWithPfs or AcceptablePfs parameters.

InitiateWithPfs

Specifies whether perfect forward secrecy (PFS) is used as initiator of the security association, and if so, what Diffie-Hellman group is used. The default is None.

None

Do not use perfect forward secrecy.

Group1

Modular exponentiation group with a 768-bit modulus.

Restriction: Group 1 is not accepted when the TCP/IP stack is configured for FIPS 140 mode on the IpFilterPolicy statement.

Group2

Modular exponentiation group with a 1024-bit modulus.

Restriction: Group 2 is not accepted when the TCP/IP stack is configured for FIPS 140 mode on the IpFilterPolicy statement.

Group5

Modular exponentiation group with a 1536-bit modulus.

Restriction: Group 5 is not accepted when the TCP/IP stack is configured for FIPS 140 mode on the IpFilterPolicy statement.

Group14

Modular exponentiation group with a 2048-bit modulus.

Group19

Random 256-bit elliptic curve group.

Restriction: This value is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details

Group20

Random 384-bit elliptic curve group.

Restriction: This value is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details

Group21

Random 521-bit elliptic curve group.

Restriction: This value is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details

Group24

Modular exponentiation group with a 2048-bit modulus and 256-bit prime order subgroup.

Restriction: This value is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details

Result: For negotiations using IKE version 1, the InitiateWithPfs selection is used when sending the proposal. For negotiations using IKE version 2, all PFS selections specified on the AcceptablePfs list are included when sending the proposal, but the InitiateWithPfs selection is sent as the first choice.

Guideline: If you are using encryption or authentication algorithms with a 128-bit key, use Diffie-Hellman groups 5,14,19,20, or 24. If you are using encryption or authentication algorithms with a key length of 256 bits or greater, use Diffie-Hellman group 21.

HowToEncapIkev2

Specifies the encapsulation mode to use when establishing IKE version 2 security associations. The default is Either.

Either

Support both tunnel and transport mode. When initiating the security association, the choice is made based on the topology of the connection. Specifically:

- If both IKE peers are hosts, then a transport mode SA is proposed. If the peer accepts the use of transport mode, then transport mode is used for the SA. If the peer responds requiring tunnel mode, then tunnel mode is used for the SA.

Tip: Specify the Transport keyword on the HowToEncapIKEv2 parameter if you want to reject the SA if the peer responds requiring tunnel mode.

- If either IKE peer is a gateway, then tunnel mode is used.

Use the mode proposed by the initiator when responding to a negotiation that was initiated by an IKE peer.

Transport

Supports only transport mode security associations. When initiating the SA, the behavior depends on the topology of the connection. Specifically:

- If both IKE peers are hosts, then a transport mode SA is proposed. If the peer accepts the use of transport mode, then transport mode is used for the SA. If the peer responds requiring tunnel mode, then the SA is deactivated and an error message logged.

Tip: Specify the Either keyword on the HowToEncapIKEv2 parameter if you want to propose transport mode but are willing to use tunnel mode if the peer responds requiring tunnel mode.

- If either IKE peer is a gateway, the local activation fails and an error message is logged.

When responding to a remote initiation, if the initiator requests tunnel mode, the negotiation is rejected with a NO_PROPOSAL_CHOSEN notification.

Tunnel

Supports only tunnel mode security associations. When initiating, only tunnel mode is proposed. When responding to a remote initiation, if the initiator requests transport mode, IKE responds without acknowledging the transport mode notification, thus forcing a tunnel mode SA to be established.

Restriction: The HowToEncapIKEv2 parameter is ignored when negotiating IKE version 1 tunnels. The encapsulation mode for IKE version 1 security associations is determined by the HowToEncap value on the selected IpDataOffer.

Restriction: This parameter is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details

PassthroughDF

When this parameter is set to No, the do not fragment bit is set to 0 (if the value Clear is specified) or 1 (if the value Set is specified) on the outer IP header for an IPv4 tunnel mode SA. When this parameter is set to Yes, the do not fragment bit is copied from the inner IP header to the outer IP header for an IPv4 tunnel mode SA. This parameter's setting is ignored for IPv6 or transport mode SAs.

Restriction: This parameter is valid only for V1R10 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details.

PassthroughDSCP

When this parameter is set to No, the Differentiated Services Code Point (DSCP) field is set to 0 on the outer IP header for a tunnel mode SA. When this parameter is set to Yes, the DSCP field is copied from the inner IP header to the outer IP header for a tunnel mode SA. This setting is ignored for transport mode SAs.

Restriction: This parameter is valid only for V1R10 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details.

IpDataOffer

An inline specification of an IpDataOffer statement to be used when initiating a phase 2 negotiation.

Restriction: A IpDynVpnAction statement is limited to a maximum of 48 IpDataOffer or IpDataOfferRef statements.

IpDataOfferRef

The name of a globally defined IpDataOffer statement to be used when initiating a phase 2 negotiation.

Restriction: A IpDynVpnAction statement is limited to a maximum of 48 IpDataOffer or IpDataOfferRef statements.

IpFilterGroup statement

Use the IpFilterGroup statement to define an IP filter group. An IpFilterGroup statement identifies a set of IpFilterRule statements that make up the IP filter group. An IpFilterGroup statement can be referenced by an IpFilterPolicy statement.

Syntax

►► IpFilterGroup — *name* — Put Braces and Parameters on Separate Lines ◄◄

Put Braces and Parameters on Separate Lines

Parameters

name

A string of 1–32 characters for the name of this IP Filter Group.

IpFilterRuleRef

The name of a globally defined IpFilterRule statement to be included in the group.

IpFilterRule

An inline specification of an IpFilterRule to be included in this group.

IpFilterPolicy statement

Use the IpFilterPolicy statement to define an IP filter policy. The IpFilterPolicy statement can contain a combination of references to IpFilterGroup statements and IpFilterRule statements and inline IpFilterRule statements.

Communication Server's integrated IP filtering is enabled for a stack when IPSECURITY is specified on the IPCONFIG statement of that stack's TCP/IP profile. When Communication Server's integrated IP filtering is enabled, IP packets are subject to the IP filters generated by the applicable IpFilterPolicy statement. IP filters are generated in the order specified on the IpFilterPolicy statement. If a reference to an IpFilterGroup statement is encountered, all the IP filters for that group are generated in the order referenced by the IpFilterGroup statement.

Requirement: The IpFilterPolicy statement is required in order to define IP filters to the Policy Agent.

The IpFilterPolicy statement can appear in the common IPsec policy file, a stack-specific IPsec policy file, or both. If it appears in both, Policy Agent only uses the statement contained in the stack-specific IPsec policy file. It should appear at most once only in each file. If it appears multiple times in a file, the last one encountered is used.

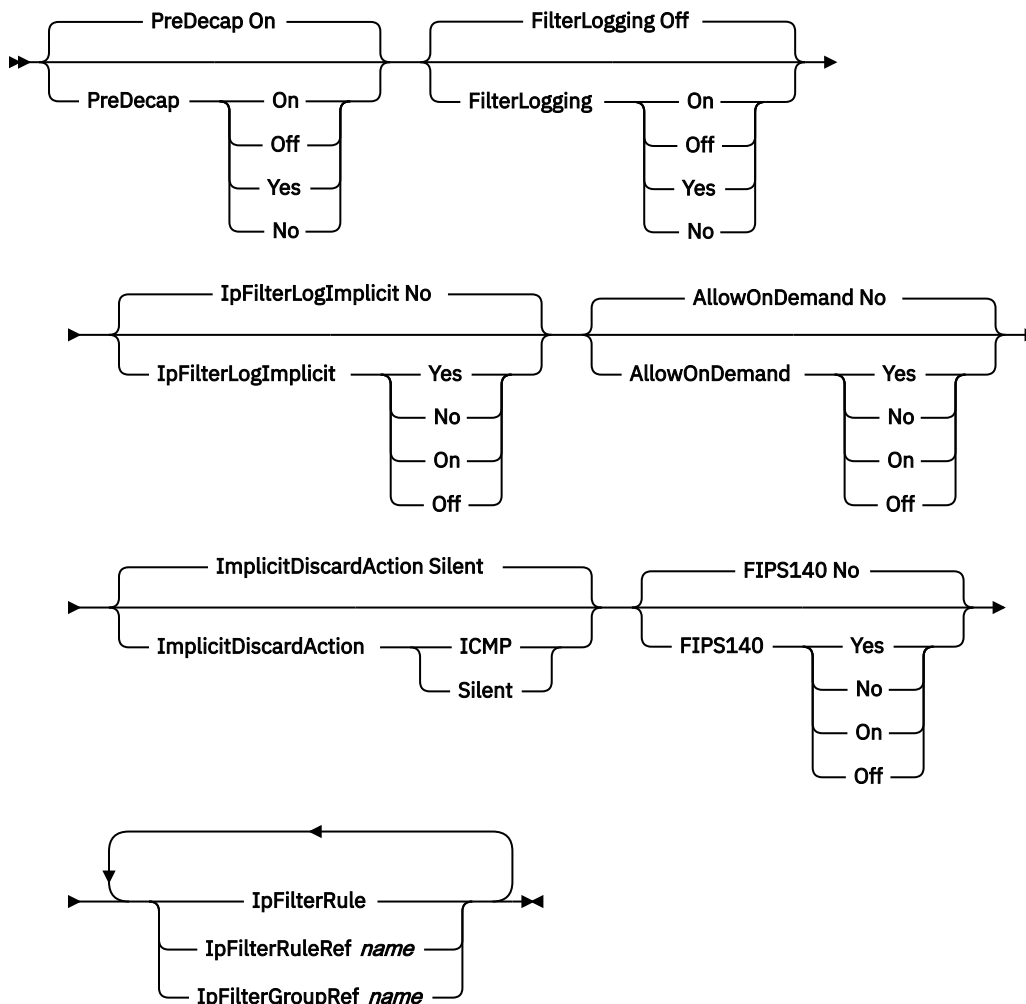

Syntax

➤ IpFilterPolicy — Put Braces and Parameters on Separate Lines ➤

Put Braces and Parameters on Separate Lines

IPFilterPolicy Parameters

Parameters

PreDecap

Indicates whether AH/ESP packets should be filtered before being decapsulated.

FilterLogging

Indicates whether packet filter logging is enabled or disabled. The log messages controlled by this parameter are EZD0814I, EZD0815I, EZD0821I, EZD0832I, EZD0833I, EZD0836I, and EZD0822I.

If FilterLogging is enabled, then the log setting on the individual filter rules is honored. The log setting for individual rules is specified with the IpFilterLogging parameter on the IpGenericFilterAction statement referenced by the IpFilterRule statement.

If FilterLogging is disabled, then the log setting on the individual filter rules is ignored and no packet filter logging is done.

IpFilterLogImplicit

Indicates whether packet filter logging should be done for packets that are denied by the implicit deny all rule at the end of the filter table. If a packet does not match any of the filter rules defined in Policy Agent, then the packet is denied by an implicit deny all rule. Logging is done for this deny if the value of the IpFilterLogImplicit parameter is Yes and FilterLogging is enabled.

AllowOnDemand

Indicates whether OnDemand negotiations of security associations should be allowed for the case where an IpLocalStartAction is not referenced from the IpFilterRule.

ImplicitDiscardAction

Indicates the discard action that is to be applied to packets that are denied by the implicit deny all rule at the end of the filter table. If a packet does not match any of the filter rules defined in Policy Agent, then the packet is denied by an implicit deny all rule.

Silent

Specify this value to discard the packet silently.

ICMP

Specify this value to send an ICMP or ICMPv6 destination unreachable error with reason administratively prohibited to the origin of the discarded packet. ICMP errors are not generated for locally originated traffic; they are generated only for remote traffic that is being received or forwarded.

Guideline: If you specify ImplicitDiscardAction ICMP, you should create a filter rule permitting these ICMP errors.

Restriction: This parameter is valid only for V1R10 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details.

FIPS140

Specifies whether the TCP/IP stack should perform cryptographic operations by invoking cryptographic modules that are designed to meet the Level 1 security requirements documented in the Federal Information Processing Standard (FIPS) publication 140 (FIPS 140).

Yes or On

Perform all IPsec-related TCP/IP cryptographic operations using cryptographic modules that are designed to meet FIPS 140 requirements. When the value of yes or on is specified, the TCP/IP stack is running in FIPS 140 mode.

No or Off

The TCP/IP stack might perform some IPsec-related cryptographic operations using cryptographic modules that do not adhere to the FIPS 140 requirements. When the value of no or off is specified, the TCP/IP stack is not running in FIPS 140 mode.

Rule: The FIPS140 parameter may not be modified while the TCP/IP stack is running. Attempts to change the FIPS140 setting while the TCP/IP stack is running will be treated as policy configuration errors by Policy Agent.

Tip: Enabling FIPS 140 mode provides a higher degree of assurance of the integrity of the cryptographic modules that the TCP/IP stack uses, including ICSF and System SSL. However, enabling FIPS 140 mode might require additional setup and configuration, it will restrict the available set of cryptographic algorithms, and it might result in a reduction in performance. See [Cryptographic standards and FIPS 140 in z/OS Communications Server: IP Configuration Guide](#) for more information.

Restriction: This parameter is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details

IpFilterRule

An inline specification of an IpFilterRule statement to be included in the policy.

IpFilterRuleRef

The name of a globally defined IpFilterRule statement to be included in the policy.

IpFilterGroupRef

The name of a globally defined IpFilterGroup statement to be included in the policy.

Result: If the IpFilterPolicy statement is deleted, then all IpFilter policies are deleted from the corresponding stack. The stack reverts to using the filter policy defined using the IPSEC statement in the TCP/IP profile. Any IpLocalStartAction actions contained in the IpFilterPolicy statement are deleted from the IKE daemon.

IpFilterRule statement

Use the IpFilterRule statement to define one or more IP filters.

The information provided on the IpFilterRule statement is combined to generate IP filters. An IpFilterRule statement that is globally defined can be referenced by an IpFilterPolicy statement and an IpFilterGroup statement.

A generated IP filter consists of a source and destination IP address specification, a service specification, an optional time period specification, a security action, and an optional local start action. The policy condition is formed by combining IP address information with port, protocol, security class, direction, and routing information from the IpService statement or the IpServiceGroup statement. An IpTimeCondition statement identifies when the generated IP filter is in effect. Security actions include the generic (permit, deny, or ipsec) action (IpGenericFilterAction), the manual VPN tunnel action (IpManVpnAction) and the dynamic VPN tunnel action (IpDynVpnAction). The optional local start action (IpLocalStartAction) is used for local on-demand or command-line activation of dynamic VPN tunnels.

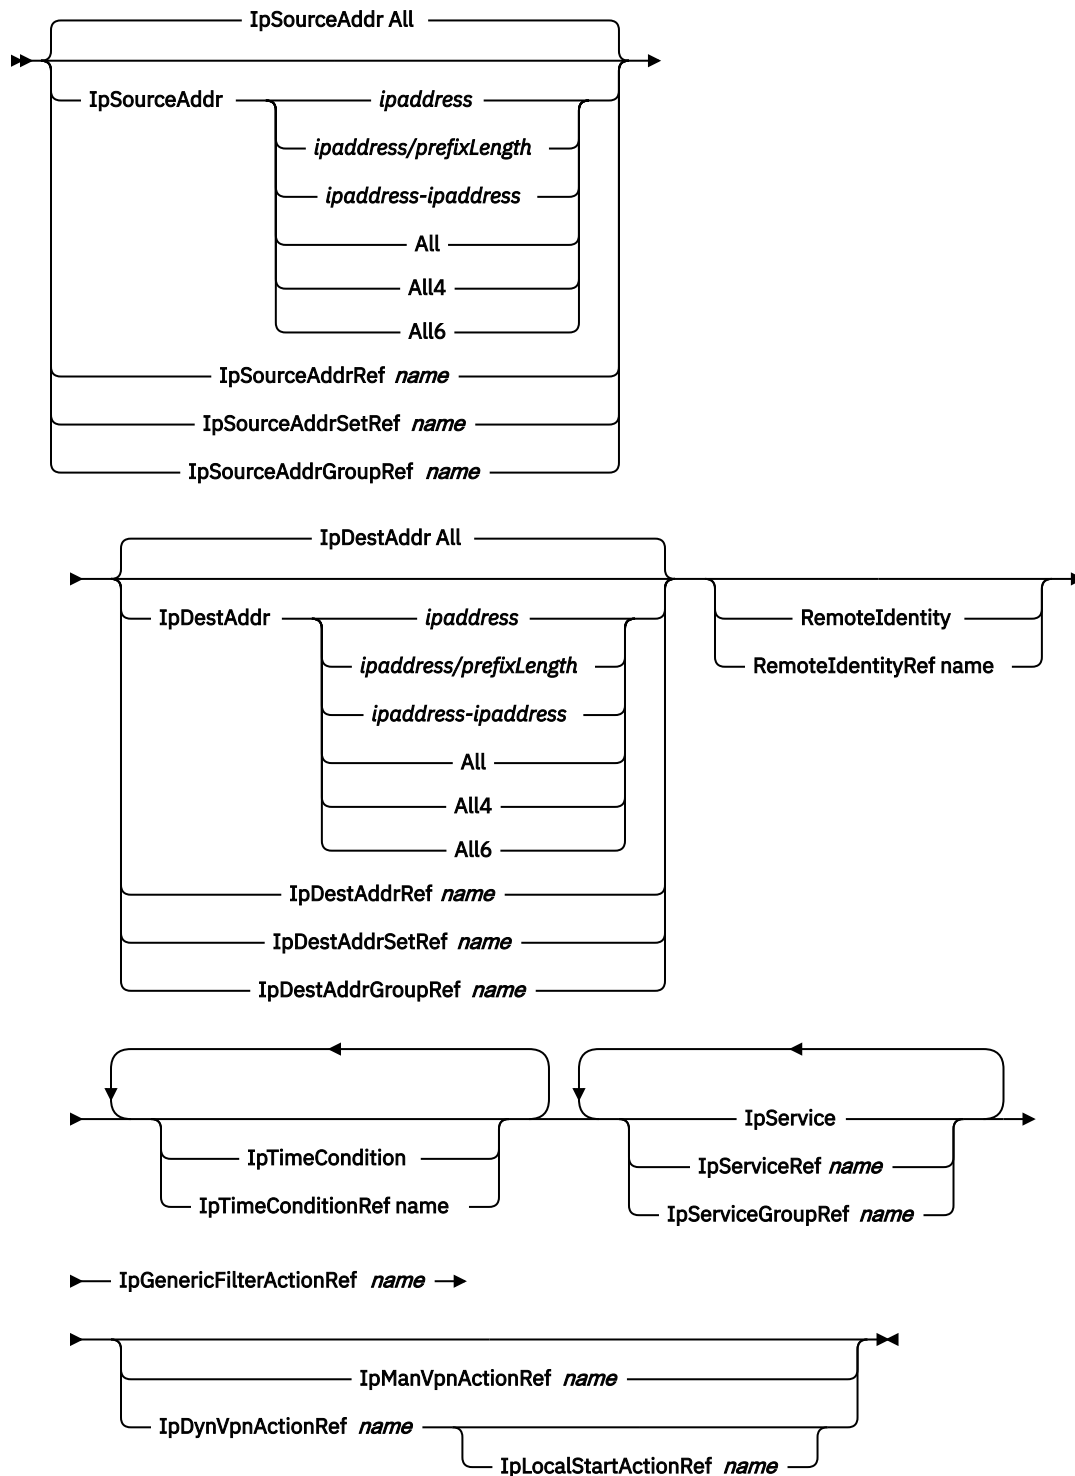

Syntax

►► IpFilterRule — *name* — Put Braces and Parameters on Separate Lines ◄◄

Put Braces and Parameters on Separate Lines

►► {
 IPFilterRule Parameters
} ◄◄

IPFilterRule Parameters

Parameters

name

A string of 1–32 characters specifying the name of this **IpFilterRule** statement. The name cannot start with a dash (-) or contain any commas (,).

IpSourceAddr

A source IP address specification.

ipaddress

A single IP address indicating the source address that must be contained in an IP packet for this rule's action to be performed.

ipaddress/prefixLength

A prefix address specification indicating the applicable source IP addresses that can be contained in an IP packet for this rule's action to be performed. The *prefixLength* is the number of unmasked leading bits in the *ipaddress* value. The *prefixLength* value can be in the range 0 - 32 for IPv4 addresses and 0 - 128 for IPv6 addresses. An IP packet matches this condition if its source address unmasked bits are identical to the defined unmasked bits.

ipaddress-ipaddress

A range of IP addresses indicating applicable source addresses that can be contained in an IP packet for this rule's action to be performed.

All

Indicates that any source IPv4 address can be contained in an IP packet for this rule's action to be performed. **All** and **All4** are interchangeable values.

All4

Indicates that any source IPv4 address can be contained in an IP packet for this rule's action to be performed.

All6

Indicates that any source IPv6 address can be contained in an IP packet for this rule's action to be performed.

IpSourceAddrRef

The name of a globally defined IpAddr statement to be used for the source IP address specification.

IpSourceAddrSetRef

The name of a globally defined IpAddrSet statement to be used for the source IP address prefix or range specification.

IpSourceAddrGroupRef

The name of a globally defined IpAddrGroup statement to be used for the source IP address specification.

IpDestAddr

A destination IP address specification.

ipaddress

A single IP address indicating the destination address that must be contained in an IP packet for this rule's action to be performed.

ipaddress/prefixLength

A prefix address specification indicating the applicable destination IP addresses that can be contained in an IP packet for this rule's action to be performed. The *prefixLength* value is the number of unmasked leading bits in the specified *ipaddress* value. The *prefixLength* value can be in the range 0 - 32 for IPv4 addresses and 0 - 128 for IPv6 addresses. An IP packet matches this condition if its destination address unmasked bits are identical to the defined unmasked bits.

ipaddress-ipaddress

A range of IP addresses indicating applicable destination addresses that can be contained in an IP packet for this rule's action to be performed.

All

Indicates that any destination IPv4 address can be contained in an IP packet for this rule's action to be performed. **All** and **All4** are interchangeable values.

All4

Indicates that any destination IPv4 address can be contained in an IP packet for this rule's action to be performed.

All6

Indicates that any destination IPv6 address can be contained in an IP packet for this rule's action to be performed.

IpDestAddrRef

The name of a globally defined IpAddr statement to be used for the destination IP address specification.

IpDestAddrSetRef

The name of a globally defined IpAddrSet statement to be used for the destination IP address prefix or range specification.

IpDestAddrGroupRef

The name of a globally defined IpAddrGroup statement to be used for the destination IP address specification.

RemoteIdentity

An inline specification of a RemoteIdentity statement. If specified, the RemoteIdentity value limits traffic that matches this filter rule. Only IPsec traffic for which the remote IKE identity matches or is contained by the RemoteIdentity matches this filter rule.

Rules:

- You can specify the RemoteIdentity parameter only for filter rules that reference an IpDynVpnAction statement.
- This parameter requires a remote activation so that the user's identity and location become known.
- Because local activations are not valid, you cannot specify the RemoteIdentity parameter for filter rules that reference an IpLocalStartAction statement.

Tip: Specify the RemoteIdentity for mobile users whose IKE identity is known but whose IP address is unknown or unpredictable.

Guideline: When you create an IpFilterRule and you specify RemoteIdentity, specify FilterByIdentity Yes on the KeyExchangeAction statement for the corresponding KeyExchangeRule statement. When you create an IPsec IpFilterRule without a RemoteIdentity, specify FilterByIdentity No on the KeyExchangeAction statement for the corresponding KeyExchangeRule statement.

Restriction: This parameter, as well as the RemoteIdentityRef parameter, is valid only for V1R10 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details.

RemoteIdentityRef

The name of a globally defined RemoteIdentity statement.

IpTimeCondition

An inline specification of an IpTimeCondition statement. There is a limit of 25 IpTimeCondition specifications and references on the IpFilterRule statement. At least one time condition must be true for the rule to be in effect.

IpTimeConditionRef

The name of a globally defined IpTimeCondition statement. There is a limit of 25 IpTimeCondition specifications and references on the IpFilterRule statement. At least one time condition must be true for the rule to be in effect.

IpService

An inline specification of an IpService statement.

IpServiceRef

The name of a globally defined IpService statement.

IpServiceGroupRef

The name of a globally defined IpServiceGroup statement.

IpGenericFilterActionRef

The name of a globally defined IpGenericFilterAction statement.

IpManVpnActionRef

The name of a globally defined IpManVpnAction statement.

Rule: If a manual tunnel should be used to provide IPsec protection of the data, then an IpManVpnAction reference is needed in addition to the IpGenericFilterAction reference. The IpGenericFilterAction reference must specify an IpFilterAction value of IpSec.

IpDynVpnActionRef

The name of a globally defined IpDynVpnAction statement.

Rule: If a dynamic tunnel should be used to provide IPsec protection, then an IpDynVpnAction reference is needed in addition to the IpGenericFilterAction reference. The IpGenericFilterAction must specify an IpFilterAction value of IpSec.

IpLocalStartActionRef

The name of a globally defined IpLocalStartAction statement.

Requirement: An IpLocalStartAction statement can be specified only in conjunction with an IpDynVpnAction statement. The IpLocalStartAction statement is required if the dynamic VPN is not a host-to-host configuration and is locally activated.

Results:

- If the IpSourceAddrGroupRef, IpDestAddrGroupRef, or IpServiceGroupRef statement is specified, multiple filters might be generated. If more than one inline or referenced IpService statement is specified, multiple filters might be generated. If the associated IpService is bidirectional, then multiple filters are generated. In this case, the base name has a number appended to uniquely identify the generated filters.
- On an `ipsec -f display -n IpFilterRuleName` command, all IP filter rules with a base name matching the IpFilterRuleName value are displayed.

Guideline: The IP address of a remote system, represented by a filter rule's destination address specification, is always a public address when the peer is behind a NAT device. The NAT device uses the private IP address of the peer to choose a public address and replaces it in the IP header. If the peer system is behind a security gateway that is behind a NAT device, the NAT device uses the private IP address of the gateway to choose a public address because the gateway first encapsulates the peer packet in a packet with the private address of the gateway.

Rules:

- Filter rules that reference an IpManVpnAction or IpDynVpnAction statement must have a direction of bidirectional specified in the IpService statement.
- All IpFilterRule statement addresses must be in the same address family (IPv4 or IPv6).
- For any IpFilterRule statement, all of its associated actions and the associated IP addresses must be in the same address family (IPv4 or IPv6).

IpGenericFilterAction statement

Use the IpGenericFilterAction statement to indicate whether selected traffic should be denied, permitted, or permitted with IPsec protection. It is also used to indicate actions (for example, logging) that are applicable to both IPsec and non-IPsec traffic.

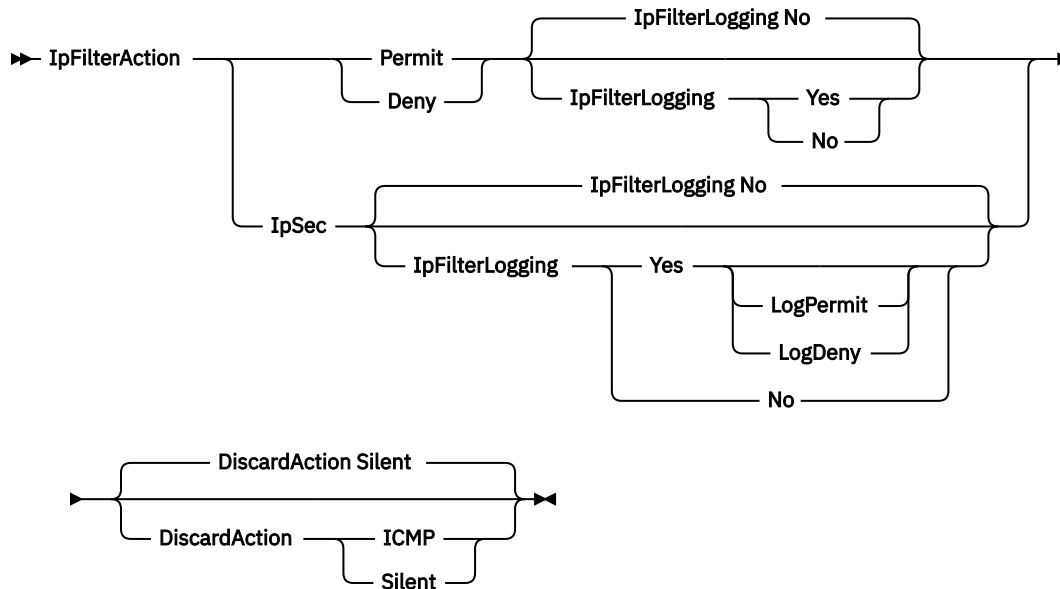

Syntax

➤ IpGenericFilterAction — *name* — Put Braces and Parameters on Separate Lines ➤

Put Braces and Parameters on Separate Lines

IpGenericFilterAction Parameters

Parameters

name

A string 1 - 32 characters in length specifying the name of this IpGenericFilterAction statement. The name cannot start with a dash (-) or contain any commas (,).

IpFilterAction

Indicates the action that should be applied to a packet matching this rule.

Permit

Traffic is permitted to flow without IPSec protection.

Deny

Traffic is denied.

IpSec

Traffic must be protected by IPSec. The IpFilterRule statement must also specify an IpManVpnAction statement or an IpDynVpnAction statement based on the type of tunnel (manual or dynamic) that is going to be used to provide IPSec protection for the traffic.

IpFilterLogging

Specifies a logging action that is applied to one or more filter rules (those that reference the IpGenericFilterAction statement). The logging action can be disabled by the setting of the FilterLogging parameter on the IpFilterPolicy statement.

IpFilterLogging (for IpFilterAction Permit or Deny)

Indicates whether a log record should be written when a packet matches this rule.

IpFilterLogging (for IpFilterAction IpSec)

No

Log record is not written when a packet matches this rule.

Yes

Log record is written when a packet matches this rule regardless of whether a valid SA is found or not.

LogPermit

Log record is written when a packet matches this rule and a valid SA is found.

LogDeny

Log record is written when a packet matches this rule and a valid SA is not found.

DiscardAction

Specifies a discard action that is applied to one or more filter rules (those that reference the `IpGenericFilterAction` statement). The discard action is applied whenever a packet is discarded. A packet might be discarded because the value `deny` is specified on the `IpFilterAction` parameter, but it might also be discarded for having a mismatch with filter policy (for example, a packet arrived over the wrong tunnel, or was sent in the clear when a tunnel was required).

Silent

Specify this value to discard the packet silently.

ICMP

Specify this value to send an ICMP or ICMPv6 destination unreachable error with reason `administratively prohibited` to the originating address of the discarded packet. ICMP errors are not generated for locally originated traffic; they are generated only for remote traffic that is being received or forwarded.

Guideline: If you specify `ImplicitDiscardAction ICMP`, create a filter rule permitting these ICMP errors.

Restriction: This parameter is valid only for V1R10 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for more information.

IpLocalStartAction statement

Use the `IpLocalStartAction` statement to indicate how to determine the local IP, remote IP, local port, remote port, protocol specification, ICMP type and code specifications, and mobility header type specification for the local activation of a dynamic VPN. It provides information about the remote and local security endpoints with which dynamic SAs should be negotiated.

The `IpLocalStartAction` is optional for host-to-host dynamic SAs that are initiated locally. If this action is not specified, default values are used to locate a matching `KeyExchangeRule` keyword. The `KeyExchangeRule` keyword is searched based on the local and remote dynamic SA endpoints to be negotiated. If the `IpLocalStartAction` is not specified on the `IpFilterRule` statement, the remote IP security endpoint is supplied based on the destination IP address in an outbound packet in the case of an `OnDemand` request, or the `RemoteIp` keyword value in the case of activation based on a `LocalDynVpnRule`. The local IP security endpoint is supplied based on the source IP address in an outbound packet, or the `LocalIp` keyword value in the case of activation based on the `LocalDynVpnRule` statement.

If the `IpLocalStartAction` statement is not specified, the `AllowOnDemand` default policy specified on the `IpFilterPolicy` is used to determine whether `OnDemand` requests are allowed. Additionally, defaults for granularity of locally initiated SAs are determined as follows:

- The IP addresses used for the security endpoints are determined based on the outbound packet (`OnDemand`) or the `LocalIp` and `RemoteIp` keywords from the `LocalDynVpnRule` statement.
- The negotiated SA is based on the protocol value specified in the rule which can either be a specific protocol or all protocols.
- For both source port and destination port, if the matching filter rule specifies a single port value or all ports, the SA is negotiated with the port value from the rule. IKE version 1 negotiation can be done only with a single port or all ports. When the rule specifies a port range and IKE version 1 is used, the negotiation is done with the port specification from the outbound packet or the `LocalDynVpnRule` statement. When the rule specifies a port range and IKE version 2 is used, the negotiation is done with the port range specification.
- If the filter rule specifies an ICMP type and code, ICMPv6 type and code, or mobility header type, the negotiated SA is based on those specifications. IKE version 1 negotiation can only be done with ICMP type and code, ICMPv6 type and code, or mobility header type specification of any.

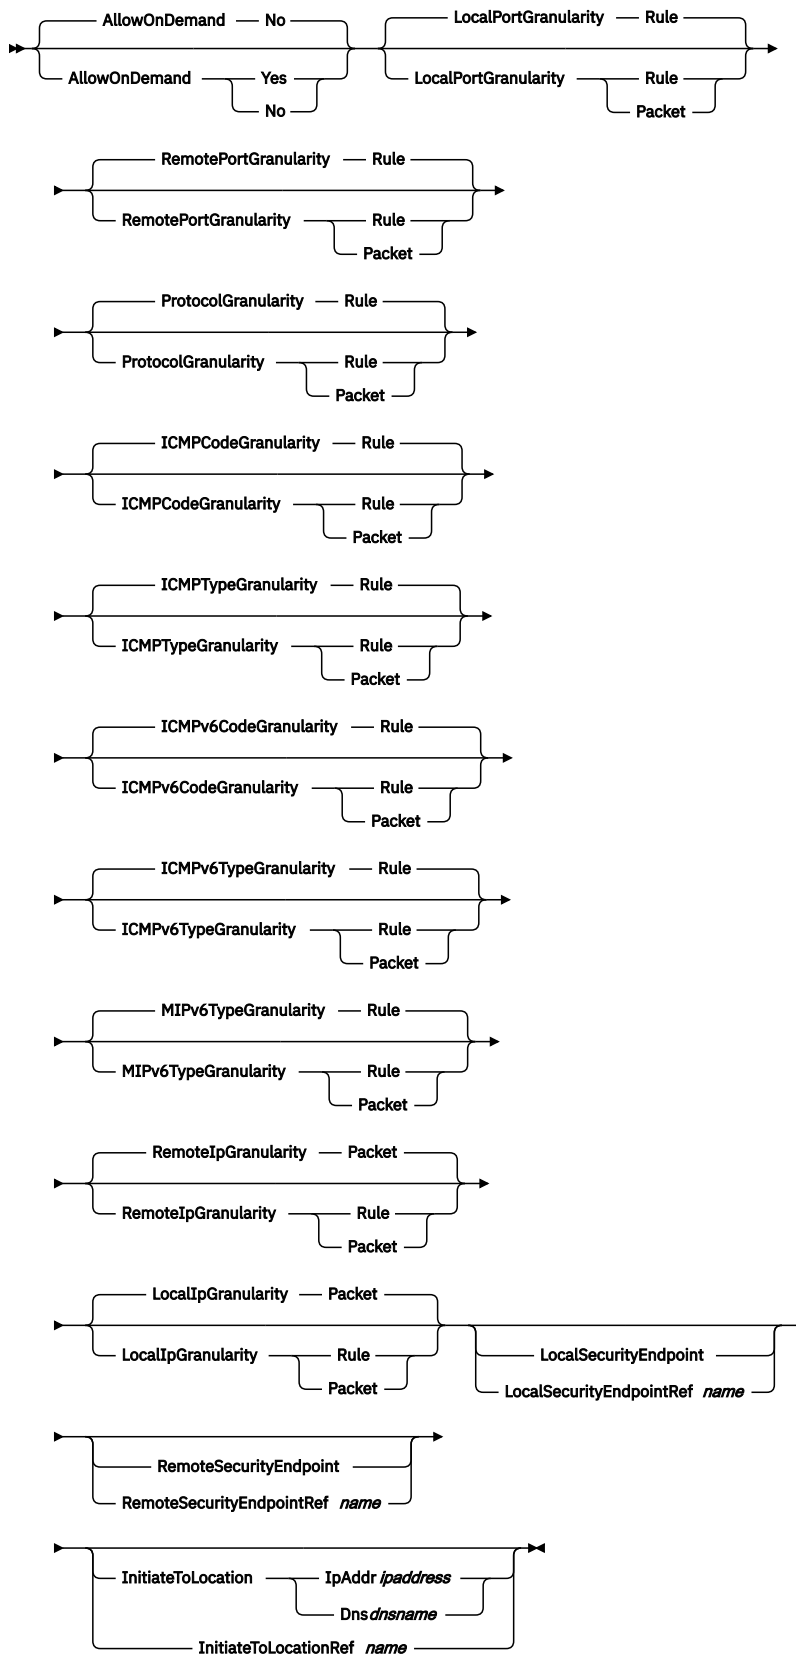

Syntax

►► IpLocalStartAction — *name* — Put Braces and Parameters on Separate Lines ►►

Put Braces and Parameters on Separate Lines

IpLocalStartAction Parameters

Parameters

name

A string 1 - 32 characters in length specifying the name of this IpLocalStartAction statement. The name cannot start with a dash (-) or contain any commas (,).

AllowOnDemand

Indicates whether outbound IP packets can result in an on demand activation of a phase 2 negotiation. The default of **No** disallows on-demand activations.

LocalIpGranularity

The LocalIpGranularity value is consulted only when creating an on-demand dynamic VPN. It specifies which of the following IP addresses should be used as the local IP address during a phase 2 negotiation:

- The source IP address specification of the matching IP filter rule
- The source IP address in the IP packet that resulted in the on-demand activation

RemoteIpGranularity

The RemoteIpGranularity is consulted only when creating an on-demand dynamic VPN. It specifies which of the following IP addresses should be used as the remote IP address during a phase 2 negotiation:

- The destination IP address specification of the matching IP filter rule
- The destination IP address in the IP packet that resulted in the on-demand activation

LocalPortGranularity

Specifies which of the following port values should be used as the local port specification during a phase 2 negotiation:

- The source port specification of the matching IP filter rule.
- The source port specification in the IP packet that resulted in the on-demand activation.

Restriction: If the matching IP filter rule has an IpService statement that specifies a local port range and the dynamic VPN is negotiated using IKE version 1, then the source port from the IP packet is used. IKE version 1 does not support port ranges for this purpose.

Tip: IKE version 1 does not support negotiating a single SA for a port range other than **All** ports. When using IKE version 1, if you want to negotiate a single phase 2 SA to cover all ports for local activations, then you must code a port specification of **All** on your IpService statement, in addition to a LocalPortGranularity of **Rule**.

RemotePortGranularity

Specifies which of the following port values should be used as the remote port specification during a phase 2 negotiation:

- The destination port specification of the matching IP filter rule.
- The destination port specification in the IP packet that resulted in the on-demand activation.

Restriction: If the matching IP filter rule has an IpService statement that specifies a destination port range and the dynamic VPN is negotiated using IKE version 1, then the destination port from the IP packet is used. IKE version 1 does not support port ranges for this purpose.

Tip: IKE version 1 does not support negotiating a single SA for a port range other than **All** ports. When using IKE version 1, if you want to negotiate a single phase 2 SA to cover all ports for local activations, then you must code a port specification of **All** on your IpService statement, in addition to a RemotePortGranularity of **Rule**.

ProtocolGranularity

Specifies which of the following protocol values should be used as the protocol specification during a phase 2 negotiation:

- The protocol specification of the matching IP filter rule
- The protocol specification in the IP packet that resulted in the on-demand activation

ICMPCodeGranularity

Specifies which of the following ICMP code values should be used during an IKE version 2 phase 2 negotiation:

- The ICMP code specification of the matching IP filter rule
- The ICMP code specification in the IP packet that resulted in the on-demand activation

The ICMPCodeGranularity parameter is ignored when IKE version 1 is used. The ICMP code specification of the matching IP filter rule is used during an IKE version 1 phase 2 negotiation. An IKE version 1 negotiation fails if the matching IP filter rule ICMP code specification contains a value other than any.

Restriction: This parameter is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details

ICMPTypeGranularity

Specifies which of the following ICMP type values should be used during an IKE version 2 phase 2 negotiation:

- The ICMP type specification of the matching IP filter rule
- The ICMP type specification in the IP packet that resulted in the on-demand activation

The ICMPTypeGranularity parameter is ignored when IKE version 1 is used. The ICMP type specification of the matching IP filter rule is used during an IKE version 1 phase 2 negotiation. An IKE version 1 negotiation fails if the matching IP filter rule ICMP type specification contains a value other than any.

Restriction: This parameter is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details

ICMPv6CodeGranularity

Specifies which of the following ICMPv6 code values should be used during an IKE version 2 phase 2 negotiation:

- The ICMPv6 code specification of the matching IP filter rule
- The ICMPv6 code specification in the IP packet that resulted in the on-demand activation

The ICMPv6CodeGranularity parameter is ignored when IKE version 1 is used. The ICMPv6 code specification of the matching IP filter rule is used during an IKE version 1 phase 2 negotiation. An IKE version 1 negotiation fails if the matching IP filter rule ICMPv6 code specification contains a value other than any.

Restriction: This parameter is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details

ICMPv6TypeGranularity

Specifies which of the following ICMPv6 type values should be used during an IKE version 2 phase 2 negotiation:

- The ICMPv6 type specification of the matching IP filter rule
- The ICMPv6 type specification in the IP packet that resulted in the on-demand activation

The ICMPv6TypeGranularity parameter is ignored when IKE version 1 is used. The ICMPv6 type specification of the matching IP filter rule is used during an IKE version 1 phase 2 negotiation. An IKE version 1 negotiation fails if the matching IP filter rule ICMPv6 type specification contains a value other than any.

Restriction: This parameter is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details

MIPv6TypeGranularity

Specifies which of the following mobility header type values should be used during an IKE version 2 phase 2 negotiation:

- The MIPv6 type specification of the matching IP filter rule

- The MIPv6 type specification in the IP packet that resulted in the on-demand activation

The MIPv6TypeGranularity parameter is ignored when IKE version 1 is used. The MIPv6 type specification of the matching IP filter rule is used during an IKE version 1 phase 2 negotiation. An IKE version 1 negotiation fails if the matching IP filter rule MIPv6 type specification contains a value other than any.

Restriction: This parameter is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details

LocalSecurityEndpoint

An inline specification of a LocalSecurityEndpoint statement.

The LocalSecurityEndpoint statement is used to locate a KeyExchangeRule statement that indicates how IKE negotiations are to be protected.

The LocalSecurityEndpoint statement is optional for host-to-host and host-to-gateway configurations. If this statement is not specified, default values are used to locate a matching KeyExchangeRule statement. The KeyExchangeRule statement is located based on the local and remote dynamic SA endpoints to be negotiated. The local IP security endpoint is supplied based on the source IP address in an outbound packet in the case of an on-demand activation or the LocalIp keyword in the case of activation based on a LocalDynVpnRule statement.

LocalSecurityEndpointRef

The name of a globally defined LocalSecurityEndpoint statement. The LocalSecurityEndpoint statement is used to locate a KeyExchangeRule statement that indicates how IKE negotiations are to be protected.

RemoteSecurityEndpoint

An inline specification of an RemoteSecurityEndpoint statement. The RemoteSecurityEndpoint statement is used to locate a KeyExchangeRule statement that indicates how IKE negotiations are to be protected.

RemoteSecurityEndpointRef

The name of a globally defined RemoteSecurityEndpoint statement. The RemoteSecurityEndpoint statement is used to locate a KeyExchangeRule statement that indicates how IKE negotiations are to be protected.

InitiateToLocation

IpAddr

The IP address specification of the remote security endpoint to be used when initiating a dynamic VPN tunnel.

Dns

The DNS name of the remote security endpoint to be used when initiating a dynamic VPN tunnel. The maximum length of DNS name is 512.

The InitiateToLocation parameter is optional for host-to-host or gateway-to-host configurations. If the parameter is not specified, the InitiateToLocation parameter is determined at run time. For on-demand activations, the destination address in the IP packet that triggered the activation is used. For activations based on a LocalDynVpnRule statement, the IP address from the RemoteIP keyword is used. The IP Address specified for InitiateToLocation should be included within the subnet or range of IP addresses specified on the RemoteSecurityEndpoint parameter location. If the RemoteSecurityEndpoint parameter specifies a single IP address for location, the InitiateToLocation parameter should match the RemoteSecurityEndpoint parameters location value.

InitiateToLocationRef

The name of a globally defined IpAddr statement for the remote security endpoint to be used when initiating a dynamic VPN tunnel.

Rules:

- All Location addresses in LocalSecurityEndpoint and RemoteSecurityEndpoint for this action must be in the same address family (IPv4 or IPv6).

- The address for the IpFilterRule statement associated with this action must be in the same address family as the Location addresses in the LocalSecurityEndpoint and RemoteSecurityEndpoint parameters.

IpManVpnAction statement

Use the IpManVpnAction statement to indicate how selected traffic between two security endpoints should be protected utilizing manually established security associations. An IpTimeCondition statement can be used to identify when the manual tunnel is installed in the stack. Activation of the manual tunnel is controlled by the Active parameter and the **ipsec** command activate/deactivate function.

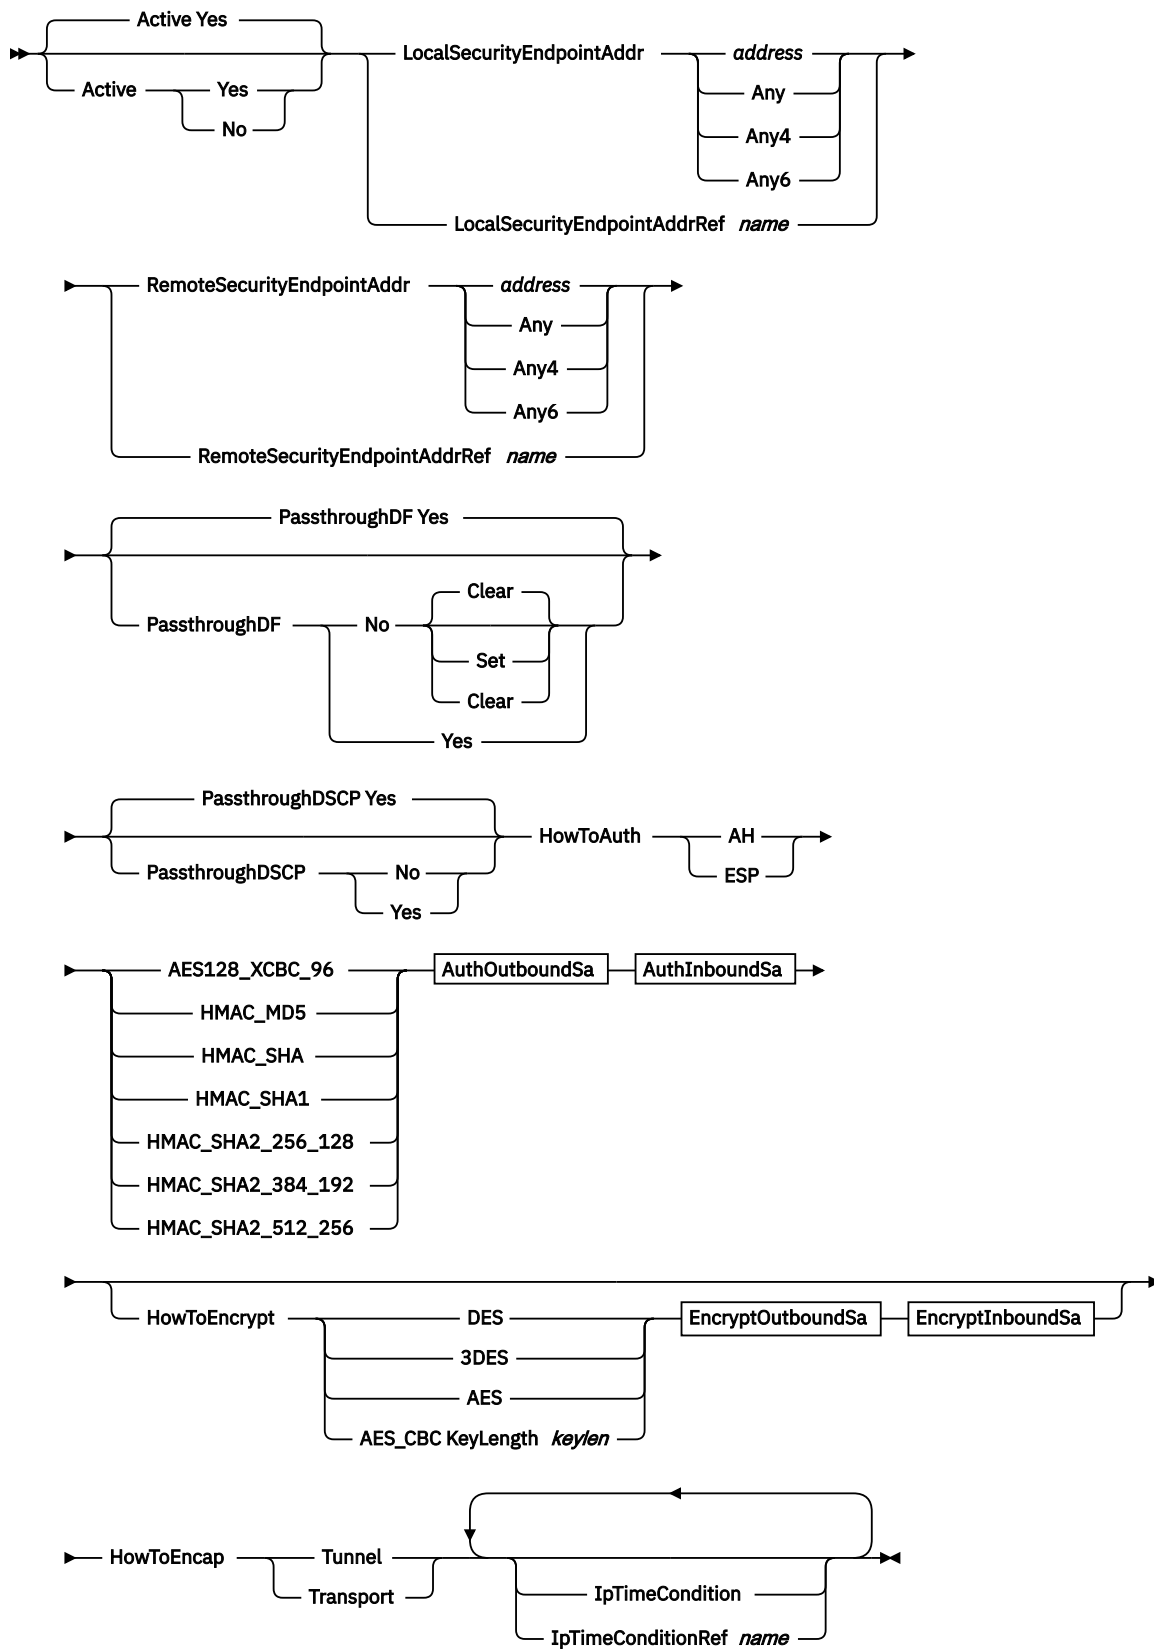

Syntax

►► IpManVpnAction — *name* — Put Braces and Parameters on Separate Lines ◄◄

Put Braces and Parameters on Separate Lines

IpManVpnAction Parameters

AuthOutboundSa

AuthOutboundSa — spi — key —>

AuthInboundSa

➤ AuthInboundSa — spi — key ➤

EncryptOutboundSa

➤ EncryptOutboundSa — spi — key ➤

EncryptInboundSa

➤ EncryptInboundSa — spi — key ➤

Parameters

name

A string 1 - 32 characters in length specifying the name of this IpManVpnAction statement. The name cannot start with a dash (-) or contain any commas (,).

Active

An indication of whether the tunnel state is set to active or inactive when the manual tunnel is installed in the stack. If a Active value of **No** is specified, then the **ipsec** command must be used to activate the manual tunnel.

Results:

- If Active **Yes** is specified (default), the IpManVpnAction statement is activated automatically when the policy is installed. If an IpTimeCondition is present on the action, that controls when the policy is installed.
- If Active **No** is specified, the IpManVpnAction statement must be manually activated using the **ipsec** command before it can be used to protect IP traffic. IP packets matching on the associated IpFilterRule are dropped until the IpManVpnAction statement is activated.

LocalSecurityEndpointAddr *name*

address

The IP address of the local security endpoint.

Restriction: The IPv6 unspecified address (::0) and IPv4 unspecified address (0.0.0.0) are not allowed.

Any

Indicates that any local IPv4 address can be used for the local security endpoint. Any and Any4 are interchangeable values.

Restriction: This parameter is valid only for V1R10 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details.

Any4

Indicates that any local IPv4 address can be used for the local security endpoint.

Restriction: This parameter is valid only for V1R10 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details.

Any6

Indicates that any local IPv6 address can be used for the local security endpoint.

LocalSecurityEndpointAddrRef

The name of a globally defined IpAddr statement for the local security endpoint.

RemoteSecurityEndpointAddr

address

The IP address of the remote security endpoint.

Restriction: The IPv6 unspecified address (::0) and IPv4 unspecified address (0.0.0.0) are not allowed.

Any

Indicates that any remote IPv4 address can be used for the remote security endpoint. Any and Any4 are interchangeable values.

Restriction: This parameter is valid only for V1R10 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details.

Any4

Indicates that any remote IPv4 address can be used for the remote security endpoint.

Restriction: This parameter is valid only for V1R10 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details

Any6

Indicates that any remote IPv6 address can be used for the remote security endpoint.

RemoteSecurityEndpointAddrRef name

The name of a globally defined IpAddr statement for the remote security endpoint.

PassthroughDF

When this value is set to No, the do not fragment bit is set to 0 (if the value Clear is specified) or 1 (if the value Set is specified) on the outer IP header for an IPv4 tunnel mode SA. When this value is set to Yes, the do not fragment bit is copied from the inner IP header to the outer IP header for an IPv4 tunnel mode SA. This setting is ignored for IPv6 or transport mode SAs.

Restriction: This parameter is valid only for V1R10 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details.

PassthroughDSCP

When this value is set to No, the Differentiated Services Code Point (DSCP) field is set to 0 on the outer IP header for a tunnel mode SA. When this value is set to Yes, the DSCP field is copied from the inner IP header to the outer IP header for a tunnel mode SA. This setting is ignored for transport mode SAs.

Restriction: This parameter is valid only for V1R10 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details.

HowToAuth

The authentication protocol and algorithm used to provide data integrity. The following protocols can be specified.

AH

Use AH headers to carry authentication data.

ESP

Use ESP headers to carry authentication data.

The following algorithms can be specified. The algorithms are ordered from least to most secure.

HMAC_MD5

Computes the authentication checksum by combining a 128-bit key, the Hash-based Message Authentication Code (HMAC) authentication algorithm and the MD5 hash algorithm.

Restriction: HMAC_MD5 is not accepted when the TCP/IP stack is configured for FIPS 140 mode on the IpFilterPolicy statement.

AES128_XCBC_96

Computes the authentication checksum using the AES128_XCBC keyed hash algorithm with a 128-bit key and a 96-bit Integrity Check Value (ICV).

Restriction: AES128_XCBC_96 is not accepted when the TCP/IP stack is configured for FIPS 140 mode on the IpFilterPolicy statement.

Restriction: This value is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details

HMAC_SHA

Deprecated and treated as a synonym for HMAC_SHA1.

HMAC_SHA1

Computes the authentication checksum by combining a 160-bit key, the HMAC authentication algorithm and the Secure Hash Algorithm (SHA) hash algorithm.

Restriction: This value is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details

HMAC_SHA2_256_128

Computes the authentication checksum using the HMAC_SHA2_256 keyed hash algorithm with a 256-bit key and 128-bit ICV.

Restriction: This value is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details

HMAC_SHA2_384_192

Computes the authentication checksum using the HMAC_SHA2_384 keyed hash algorithm with a 384-bit key and a 192-bit ICV.

Restriction: This value is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details

HMAC_SHA2_512_256

Computes the authentication checksum using the HMAC_SHA2_512 keyed hash algorithm with a 512-bit key and a 256-bit ICV.

Restriction: This value is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details

AuthOutboundSa

Specifies the SA parameters for authentication traffic transmitted outbound to the remote security endpoint.

spi

Specifies the remote Security Parameter Index. Valid values for *spi* are in the range 1 - 4 294 967 294. The set of SPI values in the range 1 - 255 are reserved to the Internet Assigned Numbers Authority (IANA) for future use.

key

Specifies the authentication key. The key must be specified in hexadecimal prefixed with '0x'. Each byte of the key represents a value in the range 00 - FF. The length of the key is determined by the associated algorithm. The key length (in bytes) for each algorithm type is:

- HMAC_MD5 (16)
- AES128_XCBC_96 (16)
- HMAC_SHA1 (20)
- HMAC_SHA2_256_128 (32)
- HMAC_SHA2_384_192 (48)
- HMAC_SHA2_512_256 (64)

AuthInboundSa

Specifies the SA parameters for authentication traffic received inbound from the remote security endpoint.

spi

Specifies the local Security Parameter Index. Valid values for *spi* are in the range 1 - 4 294 967 294.

Guidelines:

- The set of SPI values in the range 1 - 255 is reserved to the Internet Assigned Numbers Authority (IANA) for future use.
- Consider choosing an inbound SPI value in the range 256 - 4096. These values are reserved by TCP/IP for use by manual tunnels and do not conflict with any dynamic tunnels.

key

Specifies the authentication key. The key must be specified in hexadecimal prefixed with '0x'. Each byte of the key represents a value in the range 00-FF. The length of the key is determined by the associated algorithm. The key length (in bytes) for each algorithm type is:

- HMAC_MD5 (16)
- AES128_XCBC_96 (16)
- HMAC_SHA1 (20)
- HMAC_SHA2_256_128 (32)
- HMAC_SHA2_384_192 (48)
- HMAC_SHA2_512_256 (64)

HowToEncrypt

Encryption is done using the ESP protocol. Specify the encryption algorithm used to provide data confidentiality. The algorithms are ordered from least to most secure.

DES

DES encryption is used with a 56-bit key and a 64-bit initialization vector.

Restriction: DES is not accepted when the TCP/IP stack is configured for FIPS 140 mode on the IpFilterPolicy statement.

3DES

Triple DES runs the DES encryption algorithm three times and uses 192-bits, including 24 parity bits.

Rule: If 3DES is specified but is not supported by the system, then the Policy Agent fails the policy.

AES

Deprecated and treated as a synonym for AES_CBC KeyLength 128.

Rule: If AES is specified but AES encryption in CBC mode is not supported by TCP/IP, Policy Agent fails the policy.

AES_CBC KeyLength keylen

The AES algorithm is used in Cipher Block Chaining (CBC) mode with a key length *length*, either 128 or 256 bits.

Rule: If AES_CBC is specified but AES encryption in CBC mode is not supported by TCP/IP, Policy Agent fails the policy.

Restriction: This value is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details

EncryptOutboundSa

Specifies the SA parameters for encryption traffic transmitted outbound to the remote security endpoint.

spi

Specifies the remote Security Parameter Index. Valid values for *spi* are in the range 1 - 4 294 967 294. The set of SPI values in the range 1 - 255 are reserved to the Internet Assigned Numbers Authority (IANA) for future use.

key

Specifies the encryption key. The key must be specified in hexadecimal prefixed with '0x'. Each byte of the key represents a value 00-FF. The length of the key is determined by the associated algorithm. The key length (in bytes) for each algorithm type is:

- DES (8)
- 3DES_CBC (24)
- AES_CBC KeyLength 128 (16)
- AES_CBC KeyLength 256 (32)

EncryptInboundSa

Specifies the SA parameters for encryption traffic received inbound from the remote security endpoint.

spi

Specifies the local Security Parameter Index. Valid values for *spi* are in the range 1 - 4 294 967 294.

Guidelines:

- The set of SPI values in the range 1 - 255 is reserved to the Internet Assigned Numbers Authority (IANA) for future use.
- Consider choosing an inbound SPI value in the range 256 - 4 096. These values are reserved by TCP/IP for use by manual tunnels and do not conflict with any dynamic tunnels.

key

Specifies the encryption key. The key must be specified in hexadecimal prefixed with '0x'. Each byte of the key represents a value in the range 00 - FF. The length of the key is determined by the associated algorithm. The key length (in bytes) for each algorithm type is:

- DES (8)
- 3DES_CBC (24)
- AES_CBC KeyLength 128 (16)
- AES_CBC KeyLength 256 (32)

HowToEncap

An indication of whether IPSec-protected packets should be created using tunnel mode encapsulation or transport mode encapsulation.

Transport mode provides protection for the transport-layer headers and data (for example, TCP or UDP packet) inside an IP packet. This mode is used when the endpoints of the secure tunnel are the two communicating systems.

Tunnel mode provides protection for the entire IP packet. This mode is usually used for a secure tunnel between two gateways or between a gateway and a remote system.

IpTimeCondition

An inline specification of an IpTimeCondition statement. There is a limit of 25 IpTimeCondition specifications and references on the IpManVpnAction statement.

IpTimeConditionRef

The name of a globally defined IpTimeCondition statement. There is a limit of 25 IpTimeCondition specifications and references on the IpManVpnAction statement.

Rules:

- If ESP authentication is being used with encryption, the SPI values on the EncryptInboundSa and AuthInboundSa parameters must be the same value. Also, the SPI values on EncryptOutboundSa and AuthOutboundSa parameters must be the same value.
- The combination of inbound SPI value, LocalSecurityEndpointAddr, and RemoteSecurityEndpointAddr that you specify for ESP encapsulation must be unique across the entire set of IpManVpnAction statements. The following values are ESP encapsulation SPI values:
 - SPI value specified on the EncryptInboundSa parameter
 - SPI value specified on the AuthInboundSa parameter, if HowToAuth ESP is specified
- The combination of inbound SPI value, LocalSecurityEndpointAddr, and RemoteSecurityEndpointAddr that you specify for AH encapsulation must be unique across the entire set of IpManVpnAction statements. The following value is the AH encapsulation SPI value:
 - SPI value specified on the AuthInboundSa parameter, if HowToAuth AH is specified
- If ESP authentication is being used without encryption, the ESP header is present, but the payload is not encrypted (ESP_NULL).

- Replay prevention is not supported for manual security associations.
- All IpManVpnAction addresses must be in the same address family (IPv4 or IPv6).
- The addresses for the IpFilterRule statement associated with this action must be in the same address family as the addresses for this action.

Results:

- The setting of the Active parameter is applied each time the manual tunnel is installed in the stack. A change to any parameter on the IpManVpnAction statement (including the Active parameter) results in the manual tunnel being reinstalled in the stack and the Active parameter being applied. For example, in the case where the Active parameter is set to **No** and the manual tunnel has been activated with the `ipsec -m activate` command, a change to the encryption key results in the tunnel being reinstalled and the state being set to inactive.
- If both HowToAuth and HowToEncrypt are specified, the semantic is that encryption is always applied to the payload before authentication.
- If you specify Any, Any4, or Any6 for the LocalSecurityEndpointAddr or RemoteSecurityEndpointAddr parameters, and you set HowToEncap to Transport, then encapsulation preserves the original source or destination address in the IP header.
- If you specify Any, Any4, or Any6 for the LocalSecurityEndpointAddr or RemoteSecurityEndpointAddr parameters, and you set HowToEncap to Tunnel, then encapsulation preserves the original source or destination address in the IP header, if possible. If necessary, the source address is changed to an appropriate source address on the local stack.

Tips:

- Use the **ipsec** command to activate and deactivate manual tunnels.
- Manual tunnels must be activated at both security endpoints. Unlike dynamic tunnels, there is no responder mode activation for manual tunnels.
- Because multicast traffic is one-to-many but can be used both for sending and receiving, using manual tunnels for multicast requires the same SPI and keys for inbound and outbound traffic.

IpService statement

Use the IpService statement to provide a coupling between IP transport conditions, IP routing conditions, and actions.

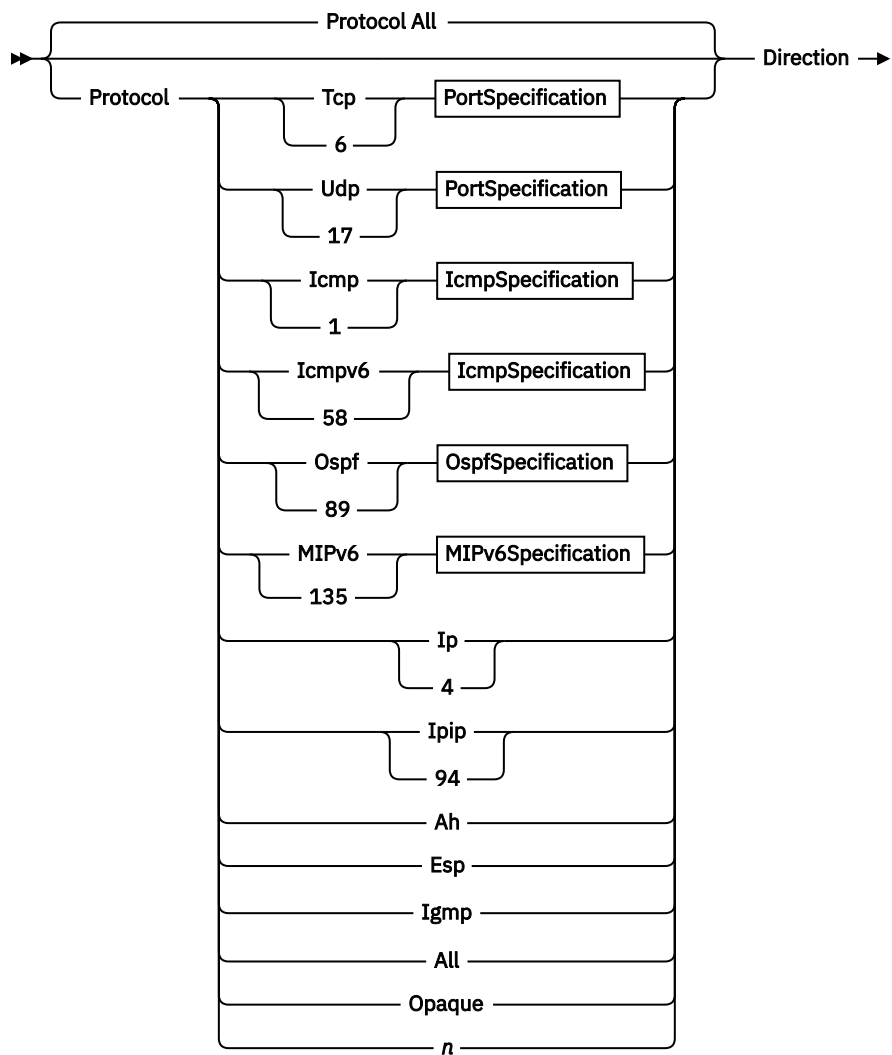

Syntax

Put Braces and Parameters on Separate Lines

IpService Parameters

PortSpecification

IcmpSpecification

MIPv6Specification

OspfSpecification

FragmentSpecification

Parameters

name

A string 1 - 32 characters in length specifying the name of this IpService statement.

Rule: If this IpService statement is not specified inline within another statement, a *name* value must be provided.

If a name is not specified for an inline IpService, a nonpersistent system name is created.

Protocol

Indicates the protocol that must be contained in an IP packet for this rule's action to be performed. If an *n* value is specified it identifies a protocol number. The value for *n* can be in the range 0 - 255. If a value of **All** is specified, then the rule applies to any protocol.

The value **Opaque** matches any IPv6 packet for which the upper-layer protocol is not known as a result of fragmentation. This parameter always matches non-initial fragments, and it also matches initial fragments if the upper-layer protocol value is not included in the first fragment. The **Opaque** value is applicable only to routed fragments because, for all local traffic, the stack applies IP filter rules only to fully assembled packets.

The protocol name **Ip** maps to the value 4, representing IP in IP encapsulation, for which IANA has assigned the name IP.

The name **IPIP** maps to the value 94, representing IP within IP encapsulation, for which IANA has assigned the name IPIP.

Restriction: The values MIPv6 and Opaque are valid only for V1R10 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details.

SourcePortRange

If a Protocol of TCP or UDP is specified, then a SourcePortRange value can be specified. The SourcePortRange value indicates the applicable source ports that must be contained in an IP packet for this rule's action to be performed.

Valid values for n are 0 - 65 535. If 0 is specified for n , then the rule applies to any source port. If n is specified as the beginning value for a range, then 0 is not a valid value.

If an m value is specified, it must be greater than or equal to n and less than 65 536.

DestinationPortRange

If a Protocol of TCP or UDP is specified, then a DestinationPortRange value can be specified. The DestinationPortRange value indicates the applicable destination ports that can be contained in an IP packet for this rule's action to be performed.

Valid values for n are in the range 0 - 65 535. If 0 is specified for n , then the rule applies to any destination port. If n is specified as the beginning value for a range, then 0 is not a valid value.

If an m value is specified, then it must be greater than or equal to n and less than 65 536.

Type

If you specify Protocol ICMP or ICMPv6, then you can specify a Type value or range. The Type value indicates the ICMP types that must be contained in an IP packet for this rule's action to be performed. Valid values for n are in the range 0 - 255. If you specify an m value, it must be greater than or equal to n and less than or equal to 255.

If you specify Protocol Ospf, then you can specify Type. The Type value indicates the OSPF types that must be contained in an IP packet for this rule's action to be performed. Valid values for n are in the range 0 - 255.

If you specify Protocol MIPv6, then you can specify a Type value or range. The Type value indicates the mobility header types that must be contained in an IP packet for this rule's action to be performed. Valid values for n are in the range 0 - 255. If you specify an m value, it must be greater than or equal to n and less than or equal to 255.

Restrictions:

- The use of a range of values for certain protocols is valid only for V1R10 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details.
- ICMP, ICMPv6 and Mobility header Type specifications other than Any are allowed for filter rules that reference an IpDynVpnAction statement, but it is valid only when the SA is negotiated using IKE version 2. Because the IKE version is not determined until IKE negotiations begin, the IKE daemon fails an SA negotiation under such a rule if the chosen KeyExchangeRule calls for IKE version 1.

Code

If you specify Protocol ICMP or ICMPv6, then you can specify a Code value or range. The Code value indicates the ICMP codes that must be contained in an IP packet for this rule's action to be performed. Valid values for n are in the range 0 - 255. If an m value is specified, it must be greater than or equal to n and less than or equal to 255.

Restrictions:

- The use of a range of values for certain protocols is valid only for V1R10 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details.
- ICMP and ICMPv6 Code specifications other than Any are allowed for filter rules that reference an IpDynVpnAction statement, but it is valid only when the SA is negotiated using IKE version 2. Because the IKE version is not determined until IKE negotiations begin, the IKE daemon fails an SA negotiation under such a rule if the chosen KeyExchangeRule calls for IKE version 1.

Direction

Specifies the direction a packet must take in order for the generated IP filters to apply.

Outbound

This value generates one IP filter. The generated rule permits or denies a packet with the specified source and destination to travel outbound.

Inbound

This value generates one IP filter. The generated rule permits or denies a packet with the specified source and destination to travel inbound.

Bidirectional

This value generates two IP filters. The first generated rule permits or denies a packet with the specified source and destination IP address or port to travel outbound. The second generated rule switches the source and destination specifications and permits or denies a packet with the switched source and destination specification to travel inbound.

InboundConnect/OutboundConnect

When Bidirectional is specified for Direction, an additional InboundConnect or OutboundConnect keyword can also be specified. These values are ignored if the protocol is not TCP. InboundConnect or OutboundConnect controls the type of packet that can send the first packet of a TCP connection (for example, the type of packet that can initiate a TCP connection). If InboundConnect and Protocol TCP are specified, then a TCP connection can be initiated only by an inbound packet. If OutboundConnect and Protocol TCP are specified, then a TCP connection can be initiated only by an outbound packet.

Routing

Specifies the type of packet that applies to this rule.

Local

Indicates that this rule applies to packets destined for this stack.

Routed

Indicates that this rule applies to packets being forwarded by this stack.

Either

Indicates that this rule applies to forwarded and non-forwarded packets.

SecurityClass

An IP packet must traverse a physical interface with a SecurityClass value of n to match the generated rule. The interface security class is defined on the LINK, INTERFACE, or DYNAMICXCF statement in the TCP/IP profile. Valid values for n can be a value in the range 0 - 255. The value 0 indicates that any interface is allowed. The SecurityClass parameter must be specified as 0 if the IpService statement is referenced by an IpFilterRule statement that also references an IpDynVpnAction statement.

FragmentsOnly

When this parameter is set to Yes, this rule matches only fragmented packets. When this parameter is set to No, this rule matches both fragments and non-fragments.

Restriction: This parameter is valid only for V1R10 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details.

Tip: Fragments are only matched in routed traffic, because the TCP/IP stack applies IP filter rules for local traffic only to fully reassembled packets.

Rule: An FragmentsOnly specification of Yes is not allowed for filter rules that reference an IpDynVpnAction statement.

Tip: To specify all ephemeral ports for the SourcePortRange or DestinationPortRange keywords, you can specify ports in the range 1 024 - 65 535.

Rules:

- Filter rules that reference an IpManVpnAction statement or IpDynVpnAction statement must have a Direction of Bidirectional specified on the IpService parameter.
- A Routing specification of Routed or Either must have one of the following:
 - A SourcePortRange and DestinationPortRange specification defaulted or configured to 0 (if applicable)

- A Type and Code specification defaulted or configured to Any (if applicable)

This restriction is valid only for V1R10 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details.

- Filter rules that reference an IpDynVpnAction must have a SecurityClass value of 0 specified on the IpService statement.
- An ICMP or ICMPv6 Type and Code specification other than Any is allowed for filter rules that reference an IpDynVpnAction statement but it is valid only when the SA is negotiated using IKE version 2. Because the IKE version is not determined until IKE negotiations begin, the IKE daemon fails an SA negotiation under such a rule if the chosen KeyExchangeRule calls for IKE version 1.
- The ICMP or ICMPv6 Code specification must be set to the Any value if a range of ICMP or ICMPv6 Types is specified.
- An OSPF Type specification is not allowed for filter rules that reference an IpDynVpnAction statement.
- A mobility header Type specification other than Any is allowed for filter rules that reference an IpDynVpnAction statement, but it is valid only when the SA is negotiated using IKE version 2. Because the IKE version is not determined until IKE negotiations begin, the IKE daemon fails an SA negotiation under such a rule if the chosen KeyExchangeRule calls for IKE version 1.
- A protocol specification of Opaque can be used only in combination with IPv6 addresses on an IpFilterRule.
- A protocol specification of Opaque is not allowed for filter rules that reference an IpDynVpnAction statement.

IpServiceGroup statement

Use the IpServiceGroup statement to define an IP service group. An IpServiceGroup statement identifies a set of IpService statements that make up the IP service group. An IpServiceGroup statement can be referenced by an IpFilterRule statement. The IpServiceGroup statement is an advanced configuration feature that results in multiple IpFilterRules being generated if the group contains or references more than one IP service condition.

Syntax

►► IpServiceGroup — *name* — Put Braces and Parameters on Separate Lines ►►

Put Braces and Parameters on Separate Lines

Parameters

name

A string 1 - 32 characters in length specifying the name of this IpServiceGroup statement.

IpService

An inline specification of an IpService statement to be included in this group.

IpServiceRef

The name of a globally defined IpService statement to be included in the group.

KeyExchangeAction statement

Use the KeyExchangeAction statement to define a key exchange action for a dynamic VPN. A key exchange indicates how key exchanges between the security endpoints should be protected. A KeyExchangeAction statement can be referenced by a KeyExchangeRule statement.

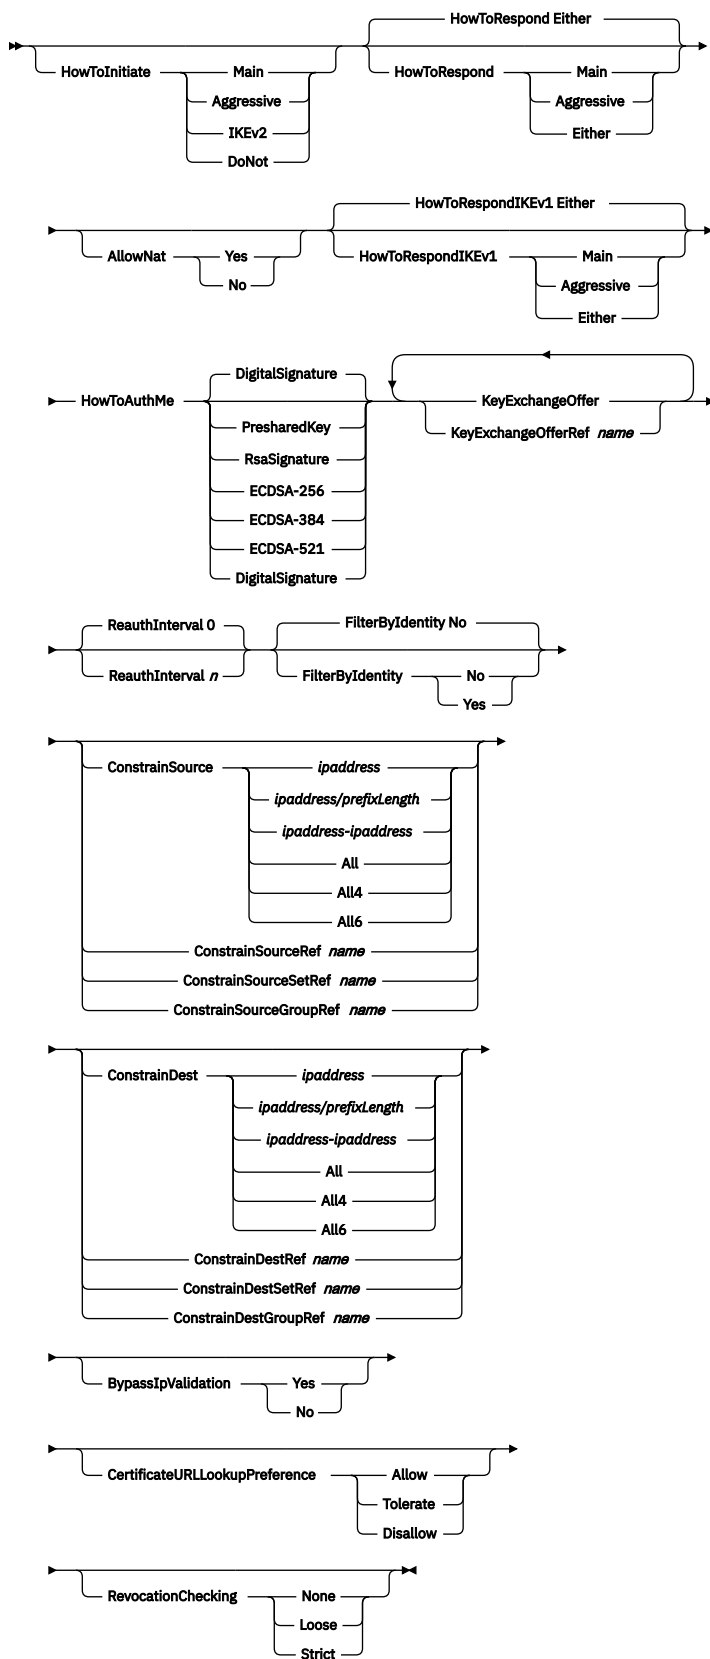

Syntax

►► KeyExchangeAction — *name* — Put Braces and Parameters on Separate Lines ◄◄

Put Braces and Parameters on Separate Lines

KeyExchangeAction Parameters

Parameters

name

A string 1 - 32 characters in length specifying the name of this KeyExchangeAction statement. The name cannot start with a dash (-) or contain any commas (,).

HowToInitiate

The negotiation mode to use as the phase 1 initiator. If this parameter is not specified, the IKE daemon will use the value from the HowToInitiate parameter in the KeyExchangePolicy.

Main

Indicates that IKE version 1 with identity protection is used when key negotiations are initiated by this system.

Aggressive

Indicates that IKE version 1 without identity protection is used when key negotiations are initiated by this system.

IKEv2

Indicates that IKE version 2 is used when key negotiations are initiated by this system.

Restriction: This value is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details

DoNot

Indicates that the local system cannot initiate a key exchange negotiation.

HowToRespond

Deprecated and treated as a synonym for HowToRespondIKEv1.

HowToRespondIKEv1

The negotiation mode to assume as the IKE version 1 phase 1 responder. The default is Either.

Restriction: This parameter is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details

Main

Requires remote systems to initiate key negotiations using IKE version 1 with identity protection.

Aggressive

Requires remote systems to initiate key negotiations using IKE version 1 without identity protection.

Either

Allows remote systems to initiate key exchange negotiations using IKE version 1 with or without identity protection.

Tip: The z/OS IKE daemon is always capable of responding with the IKE version 2 protocol. The HowToRespondIKEv1 parameter determines which IKE version 1 modes are allowed when z/OS is the responder.

HowToAuthMe

Specifies the method that remote security endpoints are to use to authenticate this security endpoint during IKE version 2 IKE_SA negotiation. If not specified, this value defaults to DigitalSignature.

PresharedKey

Indicates that the remote security endpoint is expected to authenticate this security endpoint with a pre-shared key.

RsaSignature

Indicates that the remote security endpoint is expected to authenticate this security endpoint with RSA signatures.

ECDSA-256

Indicates that the remote security endpoint is expected to authenticate this security endpoint using ECDSA with SHA-256 on the P-256 curve.

ECDSA-384

Indicates that the remote security endpoint is expected to authenticate this security endpoint using ECDSA with SHA-384 on the P-384 curve.

ECDSA-521

Indicates that the remote security endpoint is expected to authenticate this security endpoint using ECDSA with SHA-512 on the P-521 curve.

DigitalSignature

Indicates that the local security endpoint may use either RsaSignature, ECDSA-256, ECDSA-384 or ECDSA-521 when creating the digital signature for the remote security endpoint to verify. This is the default.

Restrictions:

- The HowToAuthMe keyword is ignored when IKE version 1 IKE SAs are negotiated because IKE version 1 requires that both security endpoints use the same authentication method.
- If PresharedKey is specified, the KeyExchangeRule that references the KeyExchangeAction must specify the SharedKey parameter.
- This parameter is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details.

AllowNat

Indicates whether the use of NAT traversal techniques is allowed when negotiating a phase 1 SA and subsequent phase 2 SAs that are using that phase 1 SA. The value Yes indicates that negotiations that use NAT traversal techniques are allowed. The value No indicates that negotiations that use NAT traversal techniques are not allowed. If the AllowNat parameter is specified, it overrides the AllowNat setting from the KeyExchangePolicy statement. If the AllowNat parameter is not specified, the AllowNat setting from the KeyExchangePolicy statement is used as the default.

Tip: Setting AllowNat to No prevents the IKE daemon from sending NAT payloads or processing received NAT payloads as part of the tunnel negotiation. In some cases, tunnels traversing one or more NATs can still be activated even when AllowNat is set to No. However, such tunnels are normally unusable because of the known incompatibilities between IPsec and NAT documented in RFC 3715.

KeyExchangeOffer

An inline specification of a KeyExchangeOffer statement.

Restriction: A KeyExchangeAction statement is limited to a maximum of 48 KeyExchangeOffer or KeyExchangeOfferRef statements.

KeyExchangeOfferRef

The name of a globally defined KeyExchangeOffer statement.

Restriction: A KeyExchangeAction statement is limited to a maximum of 48 KeyExchangeOffer or KeyExchangeOfferRef statements.

Rule: When you specify multiple KeyExchangeOffer parameters, configure the HowToInitiate parameter with the value Main to send multiple key exchange offers when a negotiation is initiated.

Result: When you specify multiple KeyExchangeOffer parameters, if the KeyExchangeAction parameter is configured with the value HowToInitiate Aggressive and contains multiple KeyExchangeOffer statements, the parameters of the first KeyExchangeOffer statement are used for initiating an Aggressive mode negotiation.

ReauthInterval

Specifies how often, in minutes, IKE version 2 peers reauthenticate themselves. Valid values are in the range 0-9999. The value 0 indicates that the endpoints should never reauthenticate. The default value is 0 (do not perform automatic reauthentication). Reauthentication renegotiates the keys for the IKE and reauthenticates the security endpoints. When IKE version 2 peers reauthenticate, the IKE SA and all associated child SAs must be terminated and renegotiated.

Restriction: The ReauthInterval keyword is ignored when IKE version 1 is being used between IKE peers.

Restriction: This parameter is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details.

Tip: When the remote IKE version 2 peer initiates a reauthentication at the same time as the local IKE version 2 peer, it is called a simultaneous reauthentication. Simultaneous reauthentication often results in redundant SAs. To reduce the probability of a simultaneous reauthentication, IKED shifts the timing of reauthentication by a small, random length of time. To further reduce the probability of a simultaneous reauthentication, use a higher ReauthInterval value or configure only one peer to initiate reauthentication.

FilterByIdentity

Indicates whether the peer's IKE identity is used for IP filtering purposes. IpFilterRule objects support the specification of a RemoteIdentity parameter. When this value is Yes, all IP tunnels negotiated with this peer use the RemoteIdentity parameter in addition to the traffic specification to locate the appropriate dynamic anchor IpFilterRule. When this value is No, all IP tunnels negotiated with this peer do not use the RemoteIdentity parameter to locate the appropriate dynamic anchor.

Restrictions:

- Because the RemoteIdentity parameter is supported only in combination with remote activation, FilterByIdentity Yes can be used only in combination with HowToInitiate DoNot.
- The peer is restricted to negotiating data protection only for its security endpoint address. RemoteIdentity support is intended for mobile users, who are not permitted to function as a security gateway.
- This parameter is valid only for V1R10 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details.

Guideline: When creating an IpFilterRule using a RemoteIdentity value, specify FilterByIdentity Yes on the KeyExchangeAction statement for the corresponding KeyExchangeRule statement. When creating an IPsec IpFilterRule without a RemoteIdentity value, specify FilterByIdentity No on the KeyExchangeAction statement for the corresponding KeyExchangeRule statement.

ConstrainSource

Indicates a source IP address constraint specification. Dynamic tunnel negotiations that take place under this KeyExchangeAction statement are constrained to include source data addresses that are in the range of this specification.

ipaddress

A single IP address constraining the source data address for all dynamic tunnel negotiations under this KeyExchangeAction statement.

ipaddress/prefixLength

A prefix address specification indicating the applicable source data addresses that can be included in dynamic tunnel negotiations under this KeyExchangeAction statement. The *prefixLength* value is the number of unmasked leading bits in the *ipaddress* value. The *prefixLength* value can be in the range 0 - 32 for IPv4 addresses and 0 - 128 for IPv6 addresses. A dynamic tunnel negotiation matches this condition if its source data address specification is entirely contained in the range defined by the unmasked bits for this prefix specification.

ipaddress-ipaddress

The range of IP addresses that are applicable source data addresses that can be included in dynamic tunnel negotiations under this KeyExchangeAction statement.

All

Indicates that dynamic tunnel negotiations under this KeyExchangeAction statement can include any IPv4 source data address specification. All and All4 are interchangeable values.

All4

Indicates that dynamic tunnel negotiations under this KeyExchangeAction statement can include any IPv4 source data address specification.

All6

Indicates that dynamic tunnel negotiations under this KeyExchangeAction statement can include any IPv6 source data address specification.

Restriction: This parameter, and the `ConstrainSourceRef`, `ConstrainSourceSetRef`, and `ConstrainSourceGroupRef` parameters are valid only for V1R10 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details.

ConstrainSourceRef

The name of a globally defined `IpAddr` statement that you should use to specify the source data address constraint.

ConstrainSourceSetRef

The name of a globally defined `IpAddrSet` statement that you should use to specify the source data address prefix or range constraint.

ConstrainSourceGroupRef

The name of a globally defined `IpAddrGroup` statement that you can use to specify the source data address constraint.

ConstrainDest

Indicates a destination IP address constraint specification. Dynamic tunnel negotiations that take place under this `KeyExchangeAction` statement are constrained to include only destination data addresses that are in the range of this specification.

ipaddress

A single IP address that constrains the destination data address for all dynamic tunnel negotiations under this `KeyExchangeAction` statement.

ipaddress/prefixLength

A prefix address specification indicating the applicable destination data addresses that can be included in dynamic tunnel negotiations under this `KeyExchangeAction` statement. The *prefixLength* value is the number of unmasked leading bits in the *ipaddress* value. The *prefixLength* value can be in the range 0 - 32 for IPv4 addresses and 0 - 128 for IPv6 addresses. A dynamic tunnel negotiation matches this condition if its destination data address specification is entirely contained within the range defined by the unmasked bits for this prefix specification.

ipaddress-ipaddress

The range of IP addresses that are applicable destination data addresses that can be included in dynamic tunnel negotiations under this `KeyExchangeAction` statement.

All

Indicates that dynamic tunnel negotiations under this `KeyExchangeAction` statement can include any IPv4 destination data address specification. `All` and `All4` are interchangeable values.

All4

Indicates that dynamic tunnel negotiations under this `KeyExchangeAction` statement can include any IPv4 destination data address specification.

All6

Indicates that dynamic tunnel negotiations under this `KeyExchangeAction` statement can include any IPv6 destination data address specification.

Restriction: This parameter, and the `ConstrainDestRef`, `ConstrainDestSetRef`, and `ConstrainDestGroupRef` parameters are valid only for V1R10 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details.

ConstrainDestRef name

The name of a globally defined `IpAddr` statement to be used for the destination data address constraint.

ConstrainDestSetRef name

The name of a globally defined `IpAddrSet` statement to be used for the destination data address prefix or range constraint.

ConstrainDestGroupRef name

The name of a globally defined `IpAddrGroup` statement to be used for the destination data address constraint.

BypassIpValidation

Indicates whether a check should be made to verify that the remote peer's identity matches the peer's remote IP address. A value of Yes indicates the check should be bypassed. A value of No indicates the check should be enforced. If this parameter is not specified, the BypassIpValidation setting from the KeyExchangePolicy statement is used as the default.

Restriction: The BypassIpValidation keyword is ignored when identity of the peer is not an IPv4 or IPv6 address.

Restriction: This parameter is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details

Tip: If the remote security endpoint is expected to be behind a NAT, specify a value of Yes.

CertificateURLLookupPreference

Indicates the hash and URL encoding preference of certificate payloads. If this parameter is not specified, the CertificateURLLookupPreference setting from the KeyExchangePolicy statement is used as the default.

Allow

IKED provides the remote security endpoint with an indication that it prefers to receive certificate payloads encoded in a hash and URL format. IKED processes certificate payloads encoded using a hash and URL format when they are received. IKED attempts to send certificate payloads using a hash and URL format encoding when the remote security endpoint indicates a preference to receive certificate payloads encoded in a hash and URL format.

Tolerate

IKED does not provide the remote security endpoint with an indication that it prefers to receive certificate payloads encoded in a hash and URL format. IKED processes certificate payloads encoded using a hash and URL format when they are received. IKED attempts to send certificate payloads using a hash and URL format encoding when the remote security endpoint indicates a preference to receive certificate payloads encoded in a hash and URL format.

Disallow

IKED does not provide the remote security endpoint with an indication that it prefers to receive certificate payloads encoded in a hash and URL format. IKED ignores certificate payloads encoded using a hash and URL format when they are received. IKED does not send certificate payloads using a hash and URL format.

Restriction: This keyword is ignored when IKE version 1 IKE SAs are negotiated since IKE version 1 does not support hash and URL encoding of certificate data.

Restriction: This parameter is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details

RevocationChecking

Indicates the level of revocation checking to be performed on a remote security endpoint's certificate and its corresponding certificate authority certificates.

None

No revocation checking is performed.

Loose

Revocation information is checked if available.

Strict

Revocation information must be available for all certificates and is checked for all certificates

If this parameter is not specified, the RevocationChecking setting from the KeyExchangePolicy statement is used as the default. .

Rules:

- Revocation checking is only applicable to digital signature authentication methods.
- When the mode is Loose and revocation information for a certificate is unavailable, then that certificate is considered valid.

- When the mode is Strict and revocation information for a certificate is unavailable, then that certificate is considered invalid.
- When the mode is Strict or Loose and a source of revocation information checked indicates that a certificate is revoked then the certificate is considered invalid.
- If a CRL can be obtained using the CRLDistributionPoints extension and a certificate bundle file, the CRL obtained from the CRLDistributionPoints extension is used and the CRL in the certificate bundle or certificate payload is ignored.
- When IKED is configured to use the native IKE daemon certificate service the RevocationChecking parameter is ignored.

Rule: Certificate revocation lists (CRL) received in a certificate payload are ignored.

Restrictions:

- This parameter is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details.
- Certificate revocation lists (CRL) are the only source of revocation information consulted. The CRL must be identified in the CRLDistributionPoints extension of the certificate being checked or contained in a certificate bundle file identified by the remote security endpoint.
- When the CRLDistributionPoints extension is used to retrieve a CRL at least one distribution point must contain an HTTP URL.
- IKED will only consult a CRL that contain entries for all revocation reasons.
- The native IKE daemon certificate service does not consult certificate revocation information when authenticating a digital signature. If certificate revocation information is consulted then IKED must be configured as a network security client.

KeyExchangeGroup statement

Use the KeyExchangeGroup statement to define a key exchange group. A KeyExchangeGroup statement identifies a set of KeyExchangeRule statements that make up the key exchange group. A globally defined KeyExchangeGroup statement can be referenced by a KeyExchangePolicy statement.

Syntax

►► KeyExchangeGroup — *name* — Put Braces and Parameters on Separate Lines ►►

Put Braces and Parameters on Separate Lines

Parameters

name

A string 1 - 32 characters in length specifying the name of this KeyExchangeGroup statement.

KeyExchangeRuleRef

The name of a globally defined KeyExchangeRule statement to be included in the group.

KeyExchangeRule

An inline specification of a KeyExchangeRule statement to be included in this group.

KeyExchangeOffer statement

Use the KeyExchangeOffer statement to define a key exchange offer for a dynamic VPN. A key exchange offer indicates one acceptable way to protect a key exchange for a dynamic VPN. A key exchange offer can be referenced by a KeyExchangeAction statement.

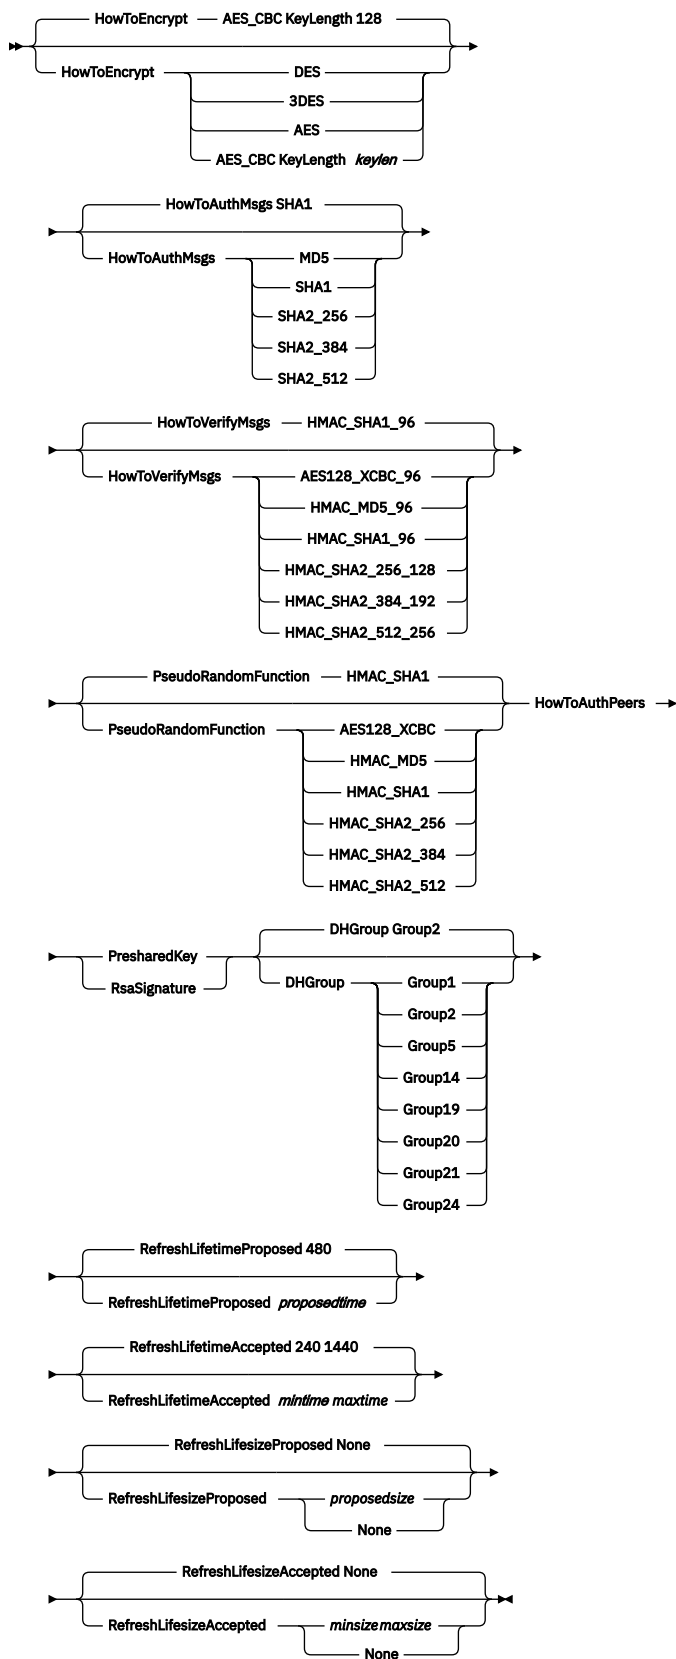

Syntax

Put Braces and Parameters on Separate Lines

KeyExchangeOffer Parameters

Parameters

name

A string 1 - 32 characters in length specifying the name of this KeyExchangeOffer statement.

Rule: If this KeyExchangeOffer statement is not specified inline within another statement, a *name* value must be provided.

If a name is not specified for an inline KeyExchangeOffer statement, a nonpersistent system name is created.

HowToEncrypt

The desired encryption policy for protecting key exchanges. The default is **AES_CBC KeyLength 128**.

DES

Use DES encryption, which uses a 56-bit key and a 64-bit initialization vector.

Restriction: DES is not accepted when the TCP/IP stack is configured for FIPS 140 mode on the IpFilterPolicy statement.

3DES

Triple DES runs the DES encryption algorithm three times and uses 192-bits, including 24 parity bits.

Rule: If 3DES is specified but is not supported by the system, then the Policy Agent fails the policy.

AES

Deprecated and treated as a synonym for AES_CBC KeyLength 128.

Rule: If AES is specified but AES encryption in CBC mode is not supported by this TCP/IP stack, Policy Agent fails the policy.

AES_CBC

The AES algorithm is used in Cipher Block Chaining (CBC) mode.

Rules:

- The key length is measured in bits, and a *keylen* of either 128 or 256 must be specified.
- If AES_CBC is specified but AES encryption is not supported by this TCP/IP stack, Policy Agent fails the policy.

Restriction: This value is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details

HowToAuthMsgs

The desired hash algorithm for authenticating IKE version 1 key exchange messages. The default is **SHA1**.

MD5

Use the HMAC MD5 algorithm.

Restriction: MD5 is not accepted when the TCP/IP stack is configured for FIPS 140 mode on the IpFilterPolicy statement.

SHA1

Use the HMAC_SHA1 algorithm.

SHA2_256

Use the HMAC_SHA2_256_128 algorithm.

Restriction: This value is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details

SHA2_384

Use the HMAC_SHA2_384_192 algorithm.

Restriction: This value is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details

SHA2_512

Use the HMAC_SHA2_512_256 algorithm.

Restriction: This value is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details

Restriction: The HowToAuthMsgs parameter is ignored for IKE version 2 SAs.

HowToVerifyMsgs

The desired authentication algorithm for verifying message integrity of IKE version 2 key exchange messages. The default is HMAC_SHA1_96.

AES128_XCBC_96

Use the AES128_XCBC algorithm to encode authentication data, with 128-bit keys and hash truncation to 96 bits.

Restriction: AES128_XCBC_96 is not accepted when the TCP/IP stack is configured for FIPS 140 mode on the IpFilterPolicy statement.

HMAC_MD5_96

Use the HMAC_MD5_96 algorithm.

Restriction: HMAC_MD5_96 is not accepted when the TCP/IP stack is configured for FIPS 140 mode on the IpFilterPolicy statement.

HMAC_SHA1_96

Use the HMAC_SHA1_96 algorithm.

HMAC_SHA2_256_128

Use the HMAC_SHA2_256 algorithm to encode authentication data, with 256-bit keys and hash truncation to 128 bits.

HMAC_SHA2_384_192

Use the HMAC_SHA2_384 algorithm to encode authentication data, with 384-bit keys and hash truncation to 192 bits.

HMAC_SHA2_512_256

Use the HMAC_SHA2_512 algorithm to encode authentication data, with 512-bit keys and hash truncation to 256 bits.

Restrictions:

- The HowToVerifyMsgs parameter is ignored for IKE version 1 SAs.
- This HowToVerifyMsgs parameter is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details.

PseudoRandomFunction

Indicates which pseudo-random function (PRF) to use when generating keying material for IKE version 2 SAs. The default is HMAC_SHA1.

AES128_XCBC

Use the AES128_XCBC algorithm.

Restriction: AES128_XCBC is not accepted when the TCP/IP stack is configured for FIPS 140 mode on the IpFilterPolicy statement.

HMAC_MD5

Use the HMAC_MD5 algorithm.

Restriction: HMAC_MD5 is not accepted when the TCP/IP stack is configured for FIPS 140 mode on the IpFilterPolicy statement.

HMAC_SHA1

Use the HMAC_SHA1 algorithm.

HMAC_SHA2_256

Use the HMAC_SHA2_256 algorithm

HMAC_SHA2_384

Use the HMAC_SHA2_384 algorithm.

HMAC_SHA2_512

Use the HMAC_SHA2_512 algorithm.

Restrictions:

- The PseudoRandomFunction parameter is ignored for IKE version 1 SAs. IKE version 1 always uses the algorithm specified on HowToAuthMsgs to determine its pseudo-random function. For example, if the HowToAuthMsgs value is MD5, then HMAC_MD5 is used.
- This PseudoRandomFunction parameter is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details.

HowToAuthPeers

Specifies the method for authenticating peers during IKE version 1 phase 1 negotiation.

PresharedKey

Use a pre-shared key to authenticate the peer.

RsaSignature

Use an RSA signature to authenticate the peer.

Restriction: The HowToAuthPeers parameter is ignored for IKE version 2 SAs.

DHGroup

Specifies the Diffie-Hellman group used during the phase 1 key exchange. The default is **Group2**.

Group1

Modular exponentiation group with a 768-bit modulus.

Restriction: Group1 is not accepted when the TCP/IP stack is configured for FIPS 140 mode on the IpFilterPolicy statement.

Group2

Modular exponentiation group with a 1024-bit modulus.

Restriction: Group2 is not accepted when the TCP/IP stack is configured for FIPS 140 mode on the IpFilterPolicy statement.

Group5

Modular exponentiation group with a 1536-bit modulus.

Restriction: Group5 is not accepted when the TCP/IP stack is configured for FIPS 140 mode on the IpFilterPolicy statement.

Group14

Modular exponentiation group with a 2048-bit modulus.

Group19

Random 256-bit elliptic curve group.

Restriction: This value is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details

Group20

Random 384-bit elliptic curve group.

Restriction: This value is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details

Group21

Random 521-bit elliptic curve group.

Restriction: This value is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details

Group24

Modular exponentiation group with a 2048-bit modulus and 256-bit prime order subgroup.

Restriction: This value is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details

Guideline: If you are using encryption or authentication algorithms with a 128-bit key, use Diffie-Hellman groups 5,14,19,20, or 24. If you are using encryption or authentication algorithms with a key length of 256 bits or greater, use Diffie-Hellman group 21.

Tip: When negotiating a new phase 1 SA and when the negotiation mode is IKE version 1 aggressive mode, only the first offer and its DH group are proposed to the peer. If the negotiation mode is IKE version 1 main mode, all offers and DH groups are proposed to the peer, who will select a particular offer and group. If the negotiation uses IKE version 2, then all offers and DH groups will be proposed, but only one DH group will be calculated in the proposal. The peer is free to either accept the DH group value used or choose a different value from one of the other offers. In that case, the IKE daemon starts the exchange again using the chosen group.

RefreshLifetimeProposed

The security association lifetime in minutes. This value is proposed when acting as the IKE version 1 initiator of a key exchange negotiation. For IKE version 2, this value determines the refresh lifetime. The default is 480.

proposedtime

The lifetime proposed (for IKE version 1) or used (for IKE version 2) for the phase 1 tunnel. Valid values are in the range 1 - 9 999. The proposed lifetime value should be within the range specified by RefreshLifetimeAccepted.

Tip: When negotiating an IKE version 2 SA, the IKE daemon uses the RefreshLifetimeProposed value in the first matching offer for the SA lifetime. Unlike IKE version 1, SA lifetimes are not negotiated under IKE version 2.

RefreshLifetimeAccepted

A range of acceptable security association lifetimes in minutes. This range is accepted when acting as the responder of an IKE version 1 key exchange negotiation. The default is 240 1440.

mintime

The minimum lifetime that can be accepted.

maxtime

The maximum lifetime that can be accepted. This value must be \geq to the *mintime* value.

Valid values for each option are in the range 1 - 9 999.

Restriction: The RefreshLifetimeAccepted parameter is ignored for IKE version 2 SAs.

RefreshLifesizeProposed

The security association lifesize in Kilobytes. If a *proposedsize* value is specified, then this value is proposed when acting as the IKE version 1 initiator of a key exchange negotiation. For IKE version 2, this value determines the refresh lifesize. If **None** is specified, then no lifesize is proposed for IKE version 1 or used for IKE version 2. The default is **None**.

proposedsize

The proposed lifesize for the negotiation. Valid values are in the range 1 - 4 194 300. The proposed lifetime value should be within the range specified by RefreshLifesizeAccepted value, if that parameter is not specified as **None**.

None

No lifesize should be proposed for IKE version 1 or used for IKE version 2. If the RefreshLifesizeProposed parameter is specified as **None**, then RefreshLifesizeAccepted value should also be specified as **None**.

Tip: When negotiating an IKE version 2 SA, the IKE daemon uses the RefreshLifesizeProposed value in the first matching offer for the SA lifesize. Unlike IKE version 1, SA lifesizes are not negotiated under IKE version 2.

RefreshLifesizeAccepted

The security association lifesize in Kbytes. If *minsize* and *maxsize* values are specified, this range is accepted when acting as the responder of key exchange negotiation. If **None** is specified, no lifesize is accepted when acting as the responder of a key exchange negotiation. The default is **None**.

minsize

The minimum lifesize that can be accepted.

maxsize

The maximum lifesize that can be accepted. This value must be \geq to the *minsize* value.

None

No lifesize is accepted. If this parameter is specified as **None**, then RefreshLifesizeProposed should also be specified as **None**.

Valid values for the *minsize* and *maxsize* options are in the range 1 - 4 194 300.

Restriction: The RefreshLifesizeAccepted parameter is ignored for IKE version 2 SAs.

KeyExchangePolicy statement

Use the KeyExchangePolicy statement to define a key exchange policy. The Key exchange policy is consulted when creating a phase 1 security association for a dynamic VPN. The KeyExchangePolicy statement can contain a combination of references to global KeyExchangeGroup statements, references to global KeyExchangeRule statements, and inline KeyExchangeRule statements.

When acting as the responder of an IKE version 1 main mode or an IKE version 2 phase 1 exchange, the IKE daemon continues negotiation without knowing the identity of the remote endpoint, as long as the suggested algorithms are supported by the IKE daemon.

Any SA agreed to before the identity of both parties are known is verified when the identity of both parties become known. If the SA is not consistent with the defined key exchange policy, the phase 1 negotiation fails. If the SA is consistent with the defined key exchange policy, the phase 1 negotiation continues.

The KeyExchangePolicy statement can appear in the common IPsec policy file, a stack-specific IPsec policy file, or both. If it appears in both, Policy Agent only uses the statement contained in the stack-specific IPsec policy file. It should appear at most only once in each file. If it appears multiple times in a file, the last one encountered is used.

Requirement: The KeyExchangePolicy statement is required to define key exchange policies to the Policy Agent.

Result: If the KeyExchangePolicy statement is deleted, then all KeyExchange policies are deleted from the IKE daemon for the corresponding stack.

Syntax

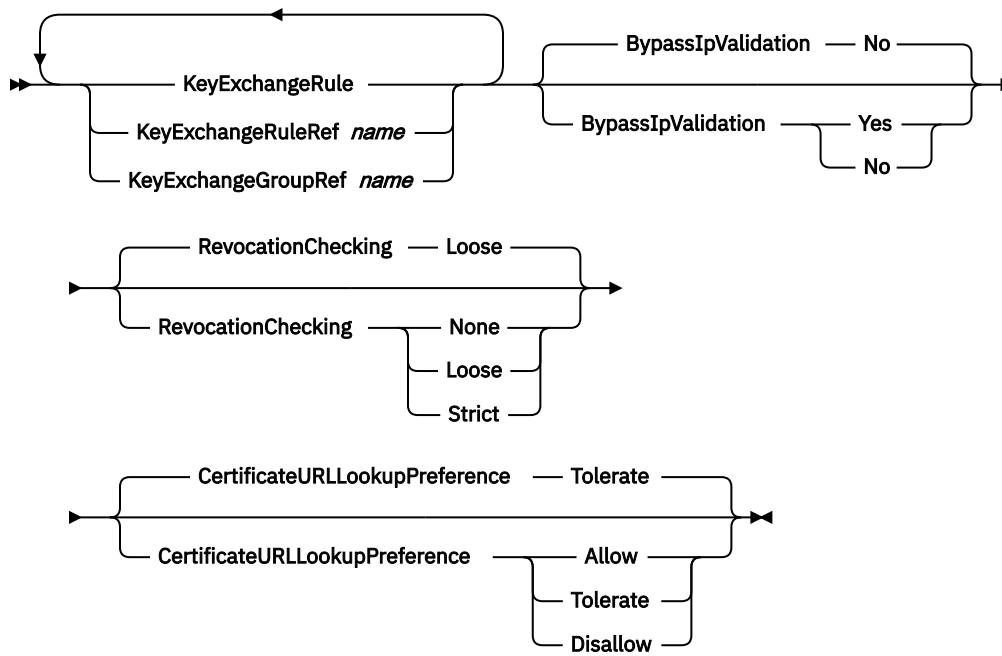

►► KeyExchangePolicy — Put Braces and Parameters on Separate Lines ◄◄

Put Braces and Parameters on Separate Lines

KeyExchangePolicy Parameters

Parameters

AllowNat

Indicates whether negotiations that use NAT traversal techniques are allowed when the AllowNat parameter is omitted from a **KeyExchangeAction** statement. The value Yes indicates that negotiations that use NAT traversal techniques are allowed when the AllowNat parameter is omitted from a **KeyExchangeAction** statement. The value No indicates that negotiations that use NAT traversal techniques are not allowed when the AllowNat parameter is omitted from a **KeyExchangeAction** statement. The default value is No.

Rule: If you change the AllowNat setting, the change is effective immediately for any new phase 1 security associations (SAs) that are negotiated. For existing phase 1 SAs, the change takes effect when the phase 1 SA is refreshed.

Tip: Setting the AllowNat to No prevents the IKE daemon from sending NAT payloads or processing received NAT payloads as part of the tunnel negotiation. In some cases, tunnels traversing one or more NATs can still be activated even when AllowNat is set to No. However, such tunnels are normally unusable because of the known incompatibilities between IPsec and NAT documented in RFC 3715.

NatKeepAliveInterval

When the IKE server is behind a NAT device it might need to send NAT keepalive messages to remote security endpoints. These keepalive messages must be sent to a remote security endpoint when all of the following conditions are true:

- IKE is behind a NAT device that dynamically maps IKE's IP address to a public IP address.
- A phase 1 SA exists with that remote security endpoint.
- No other packets have been sent to that remote security endpoint within a configured inactivity interval.

The purpose of a NAT keepalive message is to prevent a NAT device from expiring dynamic NAT mappings. NAT keep alive messages are not required when no NAT device is in front of the IKE server or when the NAT device in front of the IKE server statically maps the IKE servers IP address to a public IP address.

interval

The configured inactivity interval in seconds. Valid values are 0 or within the range 20-999. A value of 0 indicates that NAT keepalive messages should never be sent. A value in the range 20

- 999 indicates the number of seconds of inactivity that triggers the sending of a NAT keepalive message. The default is 20 seconds.

Rule: A change to the `NatKeepAliveInterval` interval is effective immediately for any new timer started. For existing timers a change takes effect when the timer expires. It is rescheduled with the new *interval* value.

Tip: The following should be considered in defining the interval value for the `NatKeepAliveInterval` parameter:

- The KeepAlive timer runs only if there is a NAT device in front of z/OS.
- If a static NAT device is in front of z/OS, then a value of 0 should be defined for the interval.
- If a dynamic NAT device is in front of z/OS, then a value less than the mapping expiration of the NAT device should be defined.

LivenessInterval

When IKE negotiates a security association using IKE version 2 (IKEv2), IKE can perform periodic liveness checks as prescribed in RFC 5996 to test whether the peer remains active. When traffic was sent but not received on an IKE SA or any of its associated dynamic tunnels, IKE initiates a liveness check after the liveness interval period is exceeded. IKE does this by sending the peer a request to which the peer is expected to respond. If, after the normal series of IKE retransmissions, the peer has not responded, the IKE SA and associated dynamic tunnels are considered non-responsive and are deleted. See [the `IkeInitWait` parameter](#) and [the `IkeRetries` parameter](#) for more information.

The purpose of the liveness check is to verify whether an IKEv2 peer is still active. This allows IKE to detect cases such as when a peer has rebooted or when dynamic tunnels are non-responsive. This allows IKE to re-establish communications with the peer in a timely manner.

Restriction: This parameter is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details

interval

The configured liveness interval in seconds. Valid values are 0 - 20999. A value of 0 indicates that liveness checks should never be performed. A value in the range 1 - 20999 indicates the number of seconds of inactivity that triggers the sending of liveness check request. The default is 30 seconds.

Rule: A change to the `LivenessInterval` is effective immediately for any new timer started. For existing timers a change takes effect when the timer expires. It is rescheduled with the new *interval* value.

Results:

1. `LivenessInterval` is used only for IKE version 2 security associations. This value is ignored for IKE version 1 security associations.
2. Liveness checks are performed only when data has been sent over the IKE SA or dynamic tunnels but not received. If no data is being either sent or received, then no liveness checks are performed.

HowToInitiate

The negotiation mode to use when initiating a `KeyExchangeAction` statement does not contain a `HowToInitiate` parameter. The default is `Main`.

Restriction: This parameter is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details

Main

Indicates that IKE version 1 with identity protection is used when key negotiations are initiated by this system.

Aggressive

Indicates that IKE version 1 without identity protection is used when key negotiations are initiated by this system.

IKEv2

Indicates that IKE version 2 is used when key negotiations are initiated by this system.

DoNot

Indicates that the local system cannot initiate a key exchange negotiation.

KeyExchangeRule

An inline specification of a KeyExchangeRule statement to be included in the policy.

KeyExchangeRuleRef

The name of a globally defined KeyExchangeRule statement to be included in the policy.

KeyExchangeGroupRef

The name of a globally defined KeyExchangeGroup statement to be included in the policy.

BypassIpValidation

Indicates whether a check should be made to verify that the remote peer's identity matches the peer's remote IP address. A value of Yes indicates the check should be bypassed. A value of No indicates the check should be enforced. The default is No,

Restriction: The BypassIpValidation keyword is ignored when the identity of the peer is not an IPv4 or IPv6 address.

Restriction: This parameter is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details

Tip: If the remote security endpoint is expected to be behind a NAT, specify a value of Yes.

CertificateURLLookupPreference

Indicates hash and URL encoding preference in certificate payloads and certificate request payloads sent and received.

Allow

IKED provides the remote security endpoint with an indication that it prefers to receive certificate payloads encoded in a hash and URL format. IKED processes certificate payloads encoded using a hash and URL format when they are received. IKED attempts to send certificate payloads using a hash and URL format encoding when the remote security endpoint indicates a preference to receive certificate payloads encoded in a hash and URL format.

Tolerate

IKED does not provide the remote security endpoint with an indication that it prefers to receive certificate payloads encoded in a hash and URL format. IKED processes certificate payloads encoded using a hash and URL format when they are received. IKED attempts to send certificate payloads using a hash and URL format encoding when the remote security endpoint indicates a preference to receive certificate payloads encoded in a hash and URL format. This is the default value.

Disallow

IKED does not provide the remote security endpoint with an indication that it prefers to receive certificate payloads encoded in a hash and URL format. IKED ignores certificate payloads encoded using a hash and URL format when they are received. IKED does not send certificate payloads using a hash and URL format.

Restriction: This keyword is ignored when IKE version 1 IKE SAs are negotiated since IKE version 1 does not support hash and URL encoding of certificate data.

Restriction: This parameter is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details

RevocationChecking

Indicates the level of revocation checking to be performed on a remote security endpoint's certificate and its corresponding certificate authority certificates. The default is Loose.

None

No revocation checking is performed.

Loose

Revocation information is checked if available.

Strict

Revocation information must be available for all certificates and is checked for all certificates

Rules:

- Revocation checking is only applicable to digital signature authentication methods.
- When the mode is Loose and revocation information for a certificate is unavailable, then that certificate is considered valid.
- When the mode is Strict and revocation information for a certificate is unavailable, then that certificate is considered invalid.
- When the mode is Strict or Loose and a source of revocation information checked indicates that a certificate is revoked then the certificate is considered invalid.
- If a CRL can be obtained using the CRLDistributionPoints extension and a certificate bundle file, the CRL obtained from the CRLDistributionPoints extension is used and the CRL in the certificate bundle or certificate payload is ignored.
- When IKED is configured to use the native IKE daemon certificate service the RevocationChecking parameter is ignored.

Rule: A CRL received in a certificate payload is ignored.

Restrictions:

- This parameter is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details.
- Certificate revocation lists (CRL) are the only source of revocation information consulted. The CRL must be identified in the CRLDistributionPoints extension of the certificate being checked or contained in a certificate bundle file identified by the remote security endpoint.
- When the CRLDistributionPoints extension is used to retrieve a CRL at least one distribution point must contain an HTTP URL.
- IKED will only consult a CRL that contain entries for all revocation reasons.
- The native IKE daemon certificate service does not consult certificate revocation information when authenticating a digital signature. If certificate revocation information is consulted then IKED must be configured as a network security client.

KeyExchangeRule statement

An IKE SA establishment might be initiated from the local system or from a remote system, and it involves several message exchanges. Depending on the initiator/responder state, and the message sequence, the IKE daemon locates a KeyExchangeRule statement to govern the policy that is used during the negotiation. The following base values are used in some combination to locate a KeyExchangeRule statement:

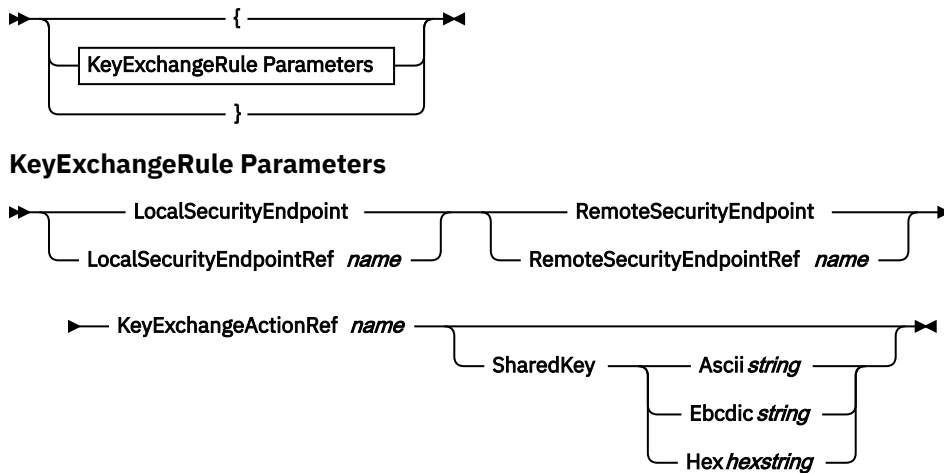

- Local IP address
- Local ID value
- Remote IP address
- Remote ID value

Depending on the message sequence, one or more of the base values might not be available, but the KeyExchangeRule statement lookup returns the best rule match available.

Syntax

►► KeyExchangeRule — *name* — Put Braces and Parameters on Separate Lines ◀◀

Put Braces and Parameters on Separate Lines

Parameters

name

A string 1 - 32 characters in length specifying the name of this KeyExchangeRule statement. The name cannot start with a dash (-) or contain any commas (,).

LocalSecurityEndpoint

An inline specification of a LocalSecurityEndpoint statement.

LocalSecurityEndpointRef

The name of a globally defined LocalSecurityEndpoint statement.

RemoteSecurityEndpoint

An inline specification of a RemoteSecurityEndpoint statement.

RemoteSecurityEndpointRef

The name of a globally defined RemoteSecurityEndpoint statement.

KeyExchangeActionRef

The name of a globally defined KeyExchangeAction statement.

SharedKey

The shared key to use with the LocalSecurityEndpoint statement and RemoteSecurityEndpoint statement pair when using a pre-shared key for authentication. The maximum length for an ASCII or EBCDIC string is 900 characters. The maximum length for a hexadecimal string is 450 bytes. The hexstring must begin with a 0x.

Examples:

SharedKey Ascii SharedKeyValue

The value is treated as an ASCII string. This specification is valuable if the sharedkey has been defined to the other endpoint as an ASCII string.

SharedKey Ebcdic SharedKeyValue

The value is treated as an EBCDIC string.

SharedKey Hex 0xC1C2C3F1F2F3

The value is treated as a hexadecimal string.

The ASCII or EBCDIC SharedKey value can be defined as a quoted string or a single value.

Rules:

- A quoted string must start and end with a double-quote (").
- A quoted string allows the SharedKey value to have embedded blanks for the attribute.
- If SharedKey value is not a quoted string then it is treated as a single value.

Results:

- Leading blanks and trailing blanks within the quoted string are removed.
- Within a quoted string, comment indicators, embedded blanks, and additional quotes are treated as part of the value for this attribute.

Restriction: When the value contains embedded blanks, you must specify the entire parameter value within the first 1-536 characters of the configuration file line.

Example SharedKey values:

```
SharedKey ASCII ASC # comment" value used: ASC
SharedKey EBCDIC EBC comment value used: EBC
SharedKey ASCII "ASC 98Z" value used: ASC 98Z
SharedKey EBCDIC EBC 98Z" value used: EBC
SharedKey ASCII "AsC 98Z value used: "AsC
SharedKey EBCDIC "Ebc " " Ebc" value used: Ebc " " Ebc
SharedKey ASCII "Asc Asc" " value used: Asc Asc
```

Tip: When negotiating using IKE version 1, the authentication method used in both directions is determined by the `HowToAuthPeers` parameter on the `KeyExchangeOffer` statement. When negotiating using IKE version 2, the IKE peers may choose different authentication methods. If you are negotiating using IKE version 2, the `HowToAuthPeers` parameter is ignored, and instead the `HowToAuthMe` parameter on the `KeyExchangeAction` statement determines the authentication method that the IKED uses for its local identity. When negotiating using IKE version 2, the peer will choose its own authentication method. If either the IKED or the remote IKE peer uses a pre-shared key for authentication, that key is to be configured using the `SharedKey` statement.

Rule: The z/OS IKE daemon requires that both security endpoints use the same pre-shared key value to authenticate itself to the remote security endpoint and to authenticate the remote security endpoint's identity.

Rule: If the z/OS IKE daemon is enabled for FIPS 140 mode, the pre-shared key's length must be at least half the length of the key size of the chosen `KeyExchangeOffer`'s `HowToAuthMsgs` (IKEv1) or `PseudoRandomFunction` (IKEv2) algorithm.

Rule: All Location addresses in the `LocalSecurityEndpoint` and `RemoteSecurityEndpoint` parameters for this rule, as well as all IP addresses in the `ConstrainSource` and `ConstrainDest` specification for this rule's action, must be in the same address family (IPv4 or IPv6).

LocalDynVpnGroup statement

Use the `LocalDynVpnGroup` statement to define a local dynamic VPN group. A `LocalDynVpnGroup` statement identifies a set of `LocalDynVpnRule` statements that make up the local dynamic VPN group. A globally defined `LocalDynVpnGroup` statement can be referenced by a `LocalDynVpnPolicy` statement.

Syntax

►► `LocalDynVpnGroup` — *name* — Put Braces and Parameters on Separate Lines ►►

Put Braces and Parameters on Separate Lines

Parameters

name

A string 1 - 32 characters in length the name of this LocalDynVpnGroup.

LocalDynVpnRuleRef

The name of a globally defined LocalDynVpnRule statement to be included in the group.

LocalDynVpnRule

An inline specification of a LocalDynVpnRule statement to be included in this group.

LocalDynVpnPolicy statement

Use the LocalDynVpnPolicy statement to identify a set of LocalDynVpnRule and LocalDynVpnGroup statements that make up the local dynamic VPN policy.

The LocalDynVpn Policy statement can appear in the common IPsec policy file, a stack-specific IPsec policy file, or both. If it appears in both, Policy Agent only uses the statement contained in the stack-specific IPsec policy file. It should appear at most only once in each file. If it appears multiple times in a file, the last one encountered is used.

Requirement: The LocalDynVpnPolicy statement is required in order to define local dynamic VPN policies to the Policy Agent.

Syntax

►► LocalDynVpnPolicy — Put Braces and Parameters on Separate Lines ◄◄

Put Braces and Parameters on Separate Lines

LocalDynVpnPolicy Parameters

Parameters

LocalDynVpnRule

An inline specification of a LocalDynVpnRule statement to be included in the policy.

LocalDynVpnRuleRef

The name of a globally defined LocalDynVpnRule statement to be included in the policy.

LocalDynVpnGroupRef

The name of a globally defined LocalDynVpnGroup statement to be included in the policy.

Result: If the LocalDynVpnPolicy statement is deleted, then all LocalDynVpn policies are deleted from the IKE daemon for the corresponding stack.

LocalDynVpnRule statement

Use the LocalDynVpnRule statement to specify the parameters that are used to negotiate a dynamic VPN that can be autoactivated or activated by an **ipsec** command. The parameters describe the traffic pattern of the data to be protected by the dynamic VPN.

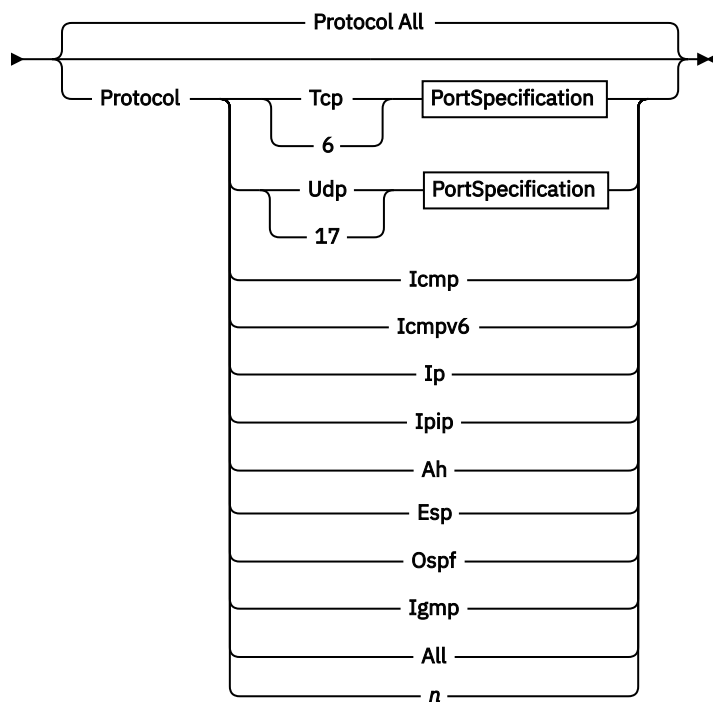

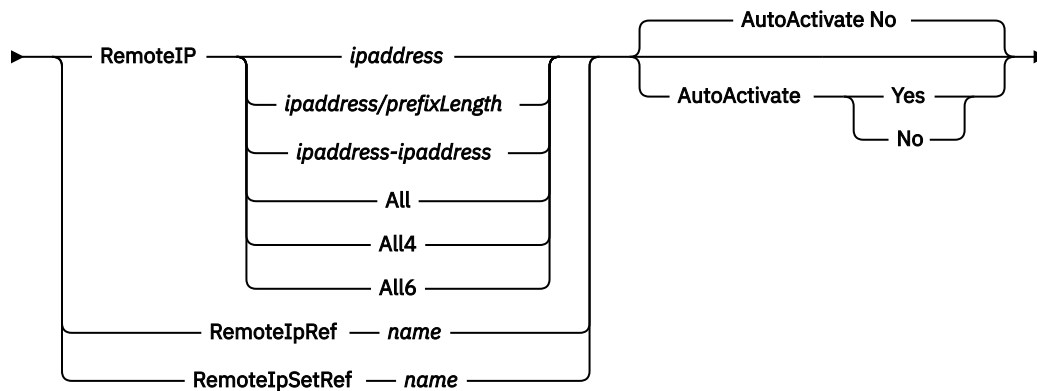

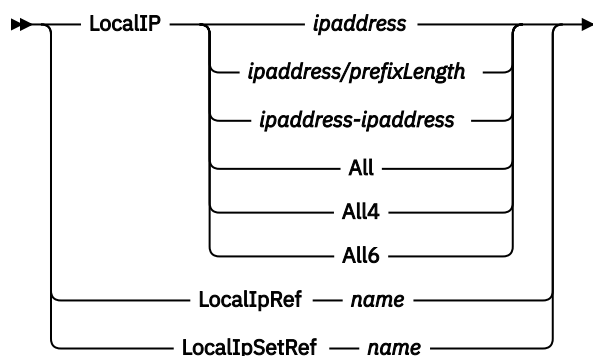

Syntax

►► LocalDynVpnRule — *name* — Put Braces and Parameters on Separate Lines ►◄

Put Braces and Parameters on Separate Lines

LocalDynVpnRule Parameters

PortSpecification

Parameters

name

A string 1 - 32 characters in length specifying the name of this LocalDynVpnRule statement. The name cannot start with a dash (-) or contain any commas (,).

LocalIp

Indicates the applicable local IP specification.

ipaddress

A single IP address indicating the applicable local IP specification.

ipaddress/prefixLength

A prefix address specification indicating the applicable local IP addresses. The *prefixLength* value is the number of unmasked leading bits in the *ipaddress* value. The *prefixLength* value can be in the range 0 - 32 for IPv4 addresses and 0 - 128 for IPv6 addresses.

ipaddress-ipaddress

A range of IP addresses indicating applicable local addresses.

All

Any local IPv4 address is applicable. **All** and **All4** are interchangeable values.

All4

Any local IPv4 address is applicable.

All6

Any local IPv6 address is applicable.

LocalIpRef

The name of a globally defined IpAddr statement to be used for the local IP address specification.

LocalIpSetRef

The name of a globally defined IpAddrSet statement to be used for the local IP address specification.

RemoteIp

Indicates the applicable remote IP specification.

ipaddress

A single IP address indicating the applicable remote IP specification.

ipaddress/prefixLength

A prefix address specification indicating the applicable remote IP addresses. The *prefixLength* value is the number of unmasked leading bits in the *ipaddress* value. The *prefixLength* value can be in the range 0 - 32 for IPv4 addresses and 0 - 128 for IPv6 addresses. An IP packet matches this condition if its remote address unmasked bits are identical to the defined unmasked bits.

ipaddress-ipaddress

A range of IP addresses indicating applicable remote addresses.

All

Any remote IPv4 address is applicable. **All** and **All4** are interchangeable values.

All4

Any remote IPv4 address is applicable.

All6

Any remote IPv6 address is applicable.

RemoteIpRef

The name of a globally defined IpAddr statement to be used for the remote IP address specification.

RemoteIpSetRef

The name of a globally defined IpAddrSet statement to be used for the remote IP address specification.

LocalDataPort

Indicates the applicable local port specification. Valid values for *n* are in the range 0 - 65 535. If 0 is specified for *n*, then the rule applies to any local port.

Restriction: This parameter can be specified only with Protocol TCP or Protocol UDP.

RemoteDataPort

Indicates the applicable remote port specification. Valid values for *n* are in the range 0 - 65 535. If 0 is specified for *n*, then the rule applies to any remote port.

Restriction: This parameter can be specified only with Protocol TCP or Protocol UDP.

Protocol

Indicates the protocol. If a numeric value is specified for *n*, it identifies an actual protocol number. The value for *n* must be less than 256.

If a value of **All** is specified, then the rule applies to any protocol.

The protocol name **Ip** maps to a value of 4, representing **ip in ip encapsulation**, for which the Internet Assigned Numbers Authority (IANA) has assigned the name **IP**.

The name **Ipip** maps to a value of 94, representing **ip within ip encapsulation**, for which IANA has assigned the name **IPIP**.

AutoActivate

If set to **Yes**, IKE attempts to activate a dynamic VPN tunnel to protect the IP traffic described by the LocalDynVpnRule statement. An activation is attempted when IKE connects to the corresponding stack and when an `ipsec -f reload` is issued for the stack associated with the LocalDynVpnRule statement.

Rules: In order for an autoactivation to occur the following conditions are required:

- A LocalDynVpnRule statement describing the traffic pattern to be protected must be defined and that statement must specify that the autoactivate option is in effect.
- The LocalDynVpnPolicy statement in effect for a stack must contain a reference to that LocalDynVpnRule statement. The reference can be a direct reference to the LocalDynVpnRule statement or a reference to a LocalDynVpnGroup statement containing the LocalDynVpnRule statement.
- A matching IP filter rule must exist and the action of that IP filter rule must be an IpDynVpnAction statement.
- A matching KeyExchangeRule value must exist.
- If IKE is configured for this stack as an NSS client for certificate services, the NSS server must be active and IKE must be connected to NSS before autoactivation is attempted.
- The remote security endpoint's IKE daemon must be active. If the IKE daemon initiates negotiation and the remote security endpoint does not respond, the IKE daemon uses its configuration parameters (IkeRetries and IkeInitWait on the IkeConfig statement) to control retry attempts. If the retries all fail, then the autoactivation fails.
- LocalIP and RemoteIP addresses must be in the same address family (IPv4 or IPv6).

Result: VPN policy is located by finding the first matching IP filter rule based on the LocalIP, RemoteIp, LocalDataPort, RemoteDataPort, and Protocol specifications.

LocalSecurityEndpoint statement

Use the LocalSecurityEndpoint statement to encapsulate a local security endpoint's IP address or host name and identity information.

Guideline: Do not use the same local identity on more than one TCP/IP stack or z/OS system image. IKED assumes that an identity is not used by any other stack, and this assumption can lead to a disruption of IPsec service for other stacks if identities are shared between stacks.

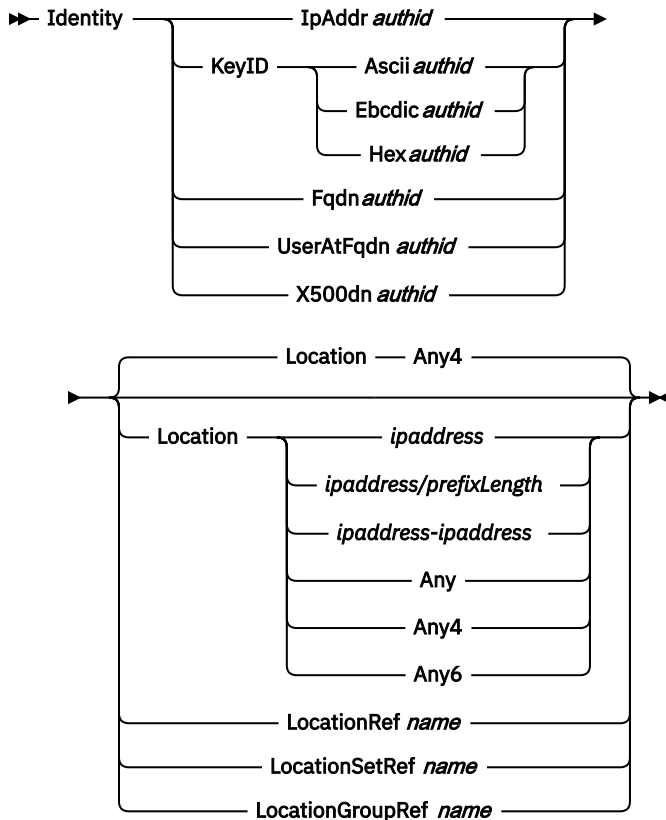

Syntax

➤ LocalSecurityEndpoint *name* Put Braces and Parameters on Separate Lines ➤

Put Braces and Parameters on Separate Lines

LocalSecurityEndpoint Parameters

Parameters

name

A string 1 - 32 characters in length specifying the name of this LocalSecurityEndpoint statement.

Rule: If this LocalSecurityEndpoint statement is not specified inline within another statement, a *name* value must be provided.

If a name is not specified for an inline LocalSecurityEndpoint statement, a nonpersistent system name is created.

Identity

The identity of the local security endpoint. This identity cannot be wildcarded.

The following identity types and formats are supported:

IpAddr

Indicates that the *authid* value is an IP address, for example, 1.2.3.4 or 1::9.

KeyID

Indicates that the *authid* value is an opaque byte stream. This identity type is intended for use with pre-shared key authentication. The ID value can be specified as an ASCII string, an EBCDIC string, or a hexadecimal string. The maximum length for an ASCII or EBCDIC string is 900 characters. The maximum length for a hexadecimal string is 450 bytes. The hexstring must begin with a 0x.

Restriction: This value is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details

Examples:

KeyID Ascii SharedKeyValue

The value is treated as an ASCII string. This specification is valuable if the key ID is defined to the other endpoint as an ASCII string.

KeyID EbcDic SharedKeyValue

The value is treated as an EBCDIC string.

KeyID Hex 0xC1C2C3F1F2F3

The value is treated as a hexadecimal string.

The ASCII or EBCDIC KeyID value can be defined as a quoted string or a single value.

Rules:

- A quoted string must start and end with a double-quote (").
- A quoted string allows the KeyID value to have embedded blanks for the attribute.
- If KeyID value is not a quoted string then it is treated as a single value.

Results:

- Leading blanks and trailing blanks within the quoted string are removed.
- Within a quoted string, comment indicators, embedded blanks, and additional quotes are treated as part of the value for this attribute.

Restriction: When the value contains embedded blanks, you must specify the entire parameter value within the first 1 536 characters of the configuration file line.

Example KeyID values:

Identity	KeyID	Ascii	ASC # comment"	value used:	ASC
Identity	KeyID	EBCDIC	EBC comment	value used:	EBC
Identity	KeyID	ASCII	"ASC 98Z"	value used:	ASC 98Z
Identity	KeyID	EBCDIC	EBC 98Z"	value used:	EBC
Identity	KeyID	ASCII	"AsC 98Z	value used:	"AsC
Identity	KeyID	EBCDIC	"Ebc " " Ebc"	value used:	Ebc " " Ebc
Identity	KeyID	ASCII	"Asc Asc" "	value used:	Asc Asc"

Fqdn

Indicates that a *authid* value is a fully qualified domain name or host name. For example: vnet.ibm.com. The maximum length accepted is 1024 characters. The Fqdn value cannot begin or end with a dot (.), or contain consecutive dots.

UserAtFqdn

Indicates that a *authid* value is a user at a fully qualified domain name or host name. The user name cannot contain a blank. For example: ibm@vnet.ibm.com. The maximum length accepted is 1024 characters. The UserAtFqdn value cannot begin or end with a dot (.), or contain consecutive dots.

X500dn

Indicates that the *authid* value is an X.500 distinguished name (DN). The DN must be specified in accordance with RFC 2253. A double-byte character is represented using the escaped UTF-8 encoding of the double-byte character in the Unicode character set. Attribute types can be specified using either attribute names or numeric object identifiers. Attribute values must represent string values. Attributes must be delimited by commas. The maximum length accepted is 1024 characters.

Table 82 on page 1058 lists the DN attribute names that are recognized by the System SSL run time. An error is returned if the DN contains an unrecognized attribute name.

Table 82. DN attribute names

Attribute	Name
C	Country
CN	Common name
DC	Domain component
E	E-mail address
EMAIL	E-mail address (preferred)
EMAILADDRESS	E-mail address
L	Locality
O	Organization name
OU	Organizational unit name
PC	Postal code
S	State or province
SN	Surname
SP	State or province
ST	State or province (preferred)
STREET	Street
T	Title

The following code is an example of a DN using attribute names and string values:

```
CN=Ronald Hoffman,OU=Endicott,O=IBM,C=US
```

The following code is the same DN using object identifiers and encoded string values. The encoded string values represent the ASN.1 DER encoding of the string. The System SSL run time supports these ASN.1 string types:

```
PRINTABLE, VISIBLE, TELETEX, IA5, UTF8, BMP, and UCS.  
2.5.4.3=#130E526F6E616C6420486F666666D616E,2.5.4.11=#1308456E6469636F7474,  
2.5.4.10=#130349424D,2.5.4.6=#13025553
```

Individual characters can be represented using escape sequences. This is useful when the character cannot be represented in a single-byte character set. The hexadecimal value for the escape sequence is the UTF-8 encoding of the character in the Unicode character set. [Table 83 on page 1058](#) shows some Unicode example letter descriptions.

Table 83. Unicode letter descriptions

Unicode letter description	10646 code	UTF-8	Quoted
LATIN CAPITAL LETTER L	U0000004C	0x4C	L
LATIN SMALL LETTER U	U00000075	0x75	u
LATIN SMALL LETTER C WITH CARON	U0000010D	0xC48D	\C4\8D
LATIN SMALL LETTER I	U00000069	0x69	i
LATIN SMALL LETTER C WITH ACUTE	U00000107	0xC487	\C4\87

Guidelines:

- The letters in the Quoted column in [Table 83 on page 1058](#) can be used to encode a surname as follows:

```
SN=Lu\C4\8Di\C4\87
```

- An X500dn type identity with a length of 256 characters is guaranteed to be accepted when it is DER-encoded. An X500dn type identity with a length approaching 1024 characters may not be accepted when it is DER-encoded.

An escape sequence can also be used for special characters that are part of the name and are not to be interpreted as delimiters. The following special characters must be represented as an escape sequence (prefixed with a backslash '\') when used as part of the name:

- A space or # character occurring at the beginning of the string
- A space character occurring at the end of the string
- One of the following characters , + " \ < > ;

For example:

```
CN=L. Eagle,OU=Jones\, Dale and Mian,O=IBM,C=US
```

Rules:

- When an X500dn type identity is specified, the DN attributes must have the same order as those of the corresponding certificate subject name.
- When an X500dn type identity is specified, the DN attributes must be delimited by commas.
- When an X500dn type identity is parsed, it is converted to an ASN.1 stream and DER-encoded. The maximum length accepted for the DER-encoded name is 1024 bytes.
- You can use comment indicators and embedded blanks as part of the value for this attribute. For example:

```
Identity X500DN cn=#my identity
value used: cn=#my identity
```

Restriction: When the value contains embedded blanks, you must specify the entire parameter value within the first 1 536 characters of the configuration file line.

Location

ipaddress

A single IP address that represents the location of the local security endpoint.

Rule: The IPv6 unspecified address (::0) is not allowed.

ipaddress/prefixLength

The range of acceptable local security endpoint IP addresses. The *prefixLength* value is the number of unmasked leading bits in the specified IP address and can have a value in the range 0 - 32 for IPv4 addresses and a value in the range 0 - 128 for IPv6 addresses.

Rule: The IPv6 unspecified address (::0/128) is not allowed.

Restrictions:

- You cannot specify a range of IP addresses for a local security endpoint that is referenced by an IpLocalStartAction statement.
- This value is valid only for V1R10 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details.

ipaddress-ipaddress

The range of IP addresses that are acceptable local security endpoint addresses.

Rule: The IPv6 unspecified address (::0::0) is not allowed.

Restrictions:

- You cannot specify a range of IP addresses for a local security endpoint that is referenced by an IpLocalStartAction statement.
- This value is valid only for V1R10 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details.

Any

The value **Any** is valid only in a host-to-host or host-to-gateway configuration. In the context of a KeyExchangeRule statement, **Any** indicates that any local IPv4 address can represent the location of the local security endpoint for this KeyExchangeRule statement. In the context of an IpLocalStartAction statement, **Any** indicates that the source IPv4 address from the outbound packet (in the case of an on-demand activation), or the LocalIp keyword (in the case of activation based on a LocalDynVpnRule statement) is used as the location of the local security endpoint. **Any** and **Any4** are interchangeable values.

Any4

The value of **Any4** is valid only in a host-to-host or host-to-gateway configuration. In the context of a KeyExchangeRule statement, **Any4** indicates that any local IPv4 address can represent the location of the local security endpoint for this KeyExchangeRule statement. In the context of an IpLocalStartAction statement, **Any4** indicates that the source IPv4 address from the outbound packet in the case of an on-demand activation, or the LocalIp keyword (in the case of activation based on a LocalDynVpnRule statement) is used as the location of the local security endpoint.

Any6

A value of **Any6** is valid only in a host-to-host or host-to-gateway configuration. In the context of a KeyExchangeRule statement, Location **Any6** indicates that any local IPv6 address can represent the location of the local security endpoint for this KeyExchangeRule statement. In the context of an IpLocalStartAction statement, Location **Any6** indicates that the source IPv6 address from the outbound packet (in the case of an on-demand activation), or the LocalIp keyword (in the case of activation based on a LocalDynVpnRule statement) is used as the location of the local security endpoint.

If LocalSecurityEndpoint is configured, then the default value is set to **Any4**.

LocationRef

The name of a globally defined IPAddr statement that represents the location of the local security endpoint.

LocationSetRef

The name of a globally defined IPAddrSet statement that represents the location of the local security endpoints.

Restrictions:

- You cannot specify a range of IP addresses for a local security endpoint that is referenced by an IpLocalStartAction statement.
- This value is valid only for V1R10 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details.

LocationGroupRef

The name of a globally defined IPAddrGroup statement that represents the location of the local security endpoints

Restrictions:

- You cannot specify a group of IP addresses for a local security endpoint that is referenced by an IpLocalStartAction statement.
- This value is valid only for V1R10 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details.

RemoteIdentity statement

Use the RemoteIdentity statement to encapsulate remote IKE identity information. This statement defines a single or wildcard value remote identity for use in negotiation of dynamic VPN tunnels.

Restriction: This statement is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details.

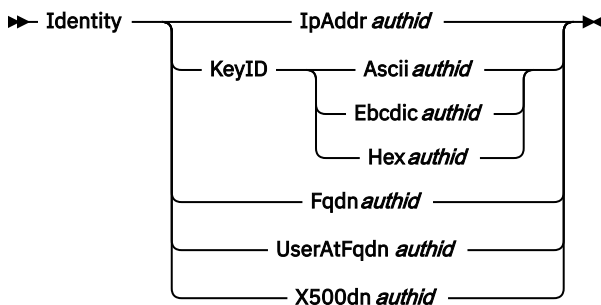

Syntax

Put Braces and Parameters on Separate Lines

RemoteIdentity Parameters

Parameters

name

A string 1 - 32 characters in length specifying the name of this RemoteIdentity statement.

Rule: If this RemoteIdentity statement is not specified as an inline statement, you must specify a *name* value.

If you do not specify a name for an inline RemoteIdentity statement, a nonpersistent system name results.

Identity

The identity of a remote security endpoint with which dynamic VPN tunnel negotiations should be allowed. The RemoteIdentity statement supports the following identity types and formats, which can be coded with a wildcard value to indicate a set of remote endpoints:

IpAddr

Indicates that the *authid* value is an IP address, for example: 1.2.3.4 or 1::9. This value can be coded with a wildcard value as a subnet or range.

The following code is a subnet example:

```
1.2.3.0/24 or 1::9/124
```

The following code is a range example:

```
1.2.3.4-1.2.3.100 or 1::0-1::F
```

KeyID

Indicates that the *authid* value is an opaque byte stream. This identity type is intended for use with pre-shared key authentication. The ID value can be specified as an ASCII string, an EBCDIC string, or a hexadecimal string. The maximum length for an ASCII or EBCDIC string is 900

characters. The maximum length for a hexadecimal string is 450 bytes. The hexstring must begin with a 0x.

Restriction: This value is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details.

Examples:

KeyID Ascii SharedKeyValue

The value is treated as an ASCII string. This specification is valuable if the key ID is defined to the other endpoint as an ASCII string.

KeyID EbcDic SharedKeyValue

The value is treated as an EBCDIC string.

KeyID Hex 0xC1C2C3F1F2F3

The value is treated as a hexadecimal string.

The ASCII or EBCDIC KeyID value can be defined as a quoted string or a single value.

Rules:

- A quoted string must start and end with a double-quote (").
- A quoted string allows the KeyID value to have embedded blanks for the attribute.
- If KeyID value is not a quoted string then it is treated as a single value.

Results:

- Leading blanks and trailing blanks within the quoted string are removed.
- Within a quoted string, comment indicators, embedded blanks, and additional quotes are treated as part of the value for this attribute.

Restriction: When the value contains embedded blanks, you must specify the entire parameter value within the first 1 536 characters of the configuration file line.

Example KeyID values:

Identity	KeyID	Ascii	ASC # comment"	value used:	ASC
Identity	KeyID	EBCDIC	EBC comment	value used:	EBC
Identity	KeyID	ASCII	"ASC 98Z"	value used:	ASC 98Z
Identity	KeyID	EBCDIC	EBC 98Z"	value used:	EBC
Identity	KeyID	ASCII	"Asc 98Z	value used:	"Asc
Identity	KeyID	EBCDIC	"Ebc " " Ebc"	value used:	Ebc " " Ebc
Identity	KeyID	ASCII	"Asc Asc" "	value used:	Asc Asc"

Fqdn

Indicates that the *authid* value is a fully qualified domain name or host name. For example, vnet.ibm.com. The maximum length accepted is 1024 characters. The Fqdn value cannot begin or end with a dot (.) and cannot contain consecutive dots.

The Fqdn value can be coded with a wildcard value in the leftmost portion preceding the first period. For example, *.ibm.com is allowed.

The leftmost portion cannot be a partial wildcard value. For example, *net.ibm.com is not allowed.

UserAtFqdn

Indicates that the *authid* value is a user at a fully qualified domain name or host name. The user name cannot contain a blank.

For example, ibm@vnet.ibm.com is allowed. The maximum length accepted is 1024 characters. The UserAtFqdn value cannot begin or end with a dot (.) and cannot contain consecutive dots.

The user portion can be a wildcard value (for example, *@vnet.ibm.com). Alternatively, the leftmost portion of the Fqdn value can be a wildcard value. For example, *.ibm.com is allowed.

X500dn

Indicates that the *authid* value is an X.500 distinguished name (DN). See [“LocalSecurityEndpoint statement”](#) on page 1055 for the DN specification.

The leftmost portion of the DN can be a wildcard value. For example, *,OU=endicott,O=ibm,C=US is allowed.

Non-initial RDNs cannot be a wildcard value. For example, CN="John Doe",*,O=ibm,C=US is not allowed.

Rule: You can use comment indicators and embedded blanks as part of the value for this attribute. For example:

```
Identity X500DN cn=#my identity
value used: cn=#my identity
```

Restriction: When the value contains embedded blanks, you must specify the entire parameter value within the first 1 536 characters of the configuration file line.

RemoteSecurityEndpoint statement

Use the RemoteSecurityEndpoint statement to encapsulate remote security endpoint IP addresses or hostnames and identity information. This statement defines identity requirements for remote security endpoints with which negotiations for dynamic VPN tunnels are allowed. The statement can also list one or more Certificate Authorities to be used with the allowed security endpoints.

Guideline: The IP address of a remote system is always a public address when the remote security endpoint is behind a NAT device. The NAT device uses the private IP address of the remote security endpoint to choose a public address and replaces it in the IP header.

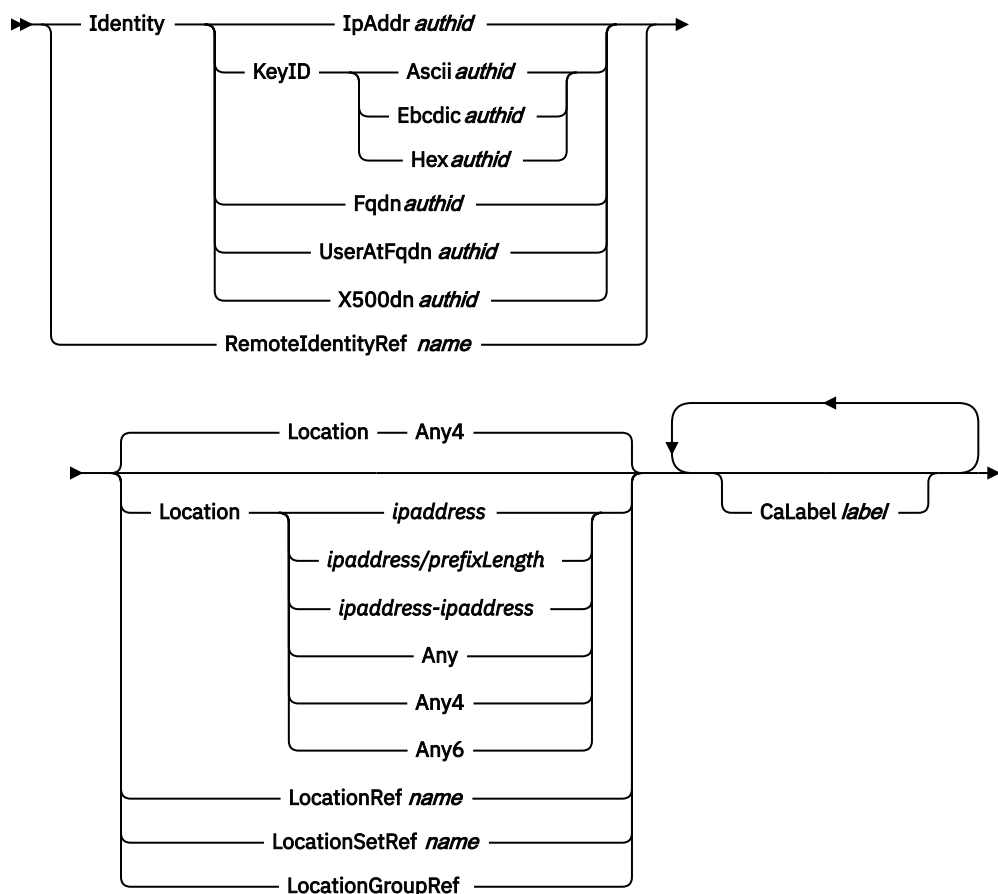

Syntax

Put Braces and Parameters on Separate Lines

RemoteSecurityEndpoint Parameters

Parameters

name

A string 1 - 32 characters in length specifying the name of this RemoteSecurityEndpoint statement.

Rule: If this RemoteSecurityEndpoint statement is not specified inline within another statement, a *name* value must be provided.

If a name is not specified for an inline RemoteSecurityEndpoint statement, a nonpersistent system name is created.

Identity

The identity of a remote security endpoint with which dynamic VPN tunnel negotiations should be allowed. The RemoteSecurityEndpoint identity supports the same identity types and formats as the LocalSecurityEndpoint identity. In addition, the RemoteSecurityEndpoint identity can be wildcarded to indicate a set of acceptable endpoints.

The following identity types and formats are supported:

IpAddr

Indicates that the *authid* value is an IP address, for example: 1.2.3.4 or 1::9. This value can be wildcarded as a subnet or range.

The following code is a subnet example:

```
1.2.3.0/24 or 1::9/124
```

The following code is a range example:

```
1.2.3.4-1.2.3.100 or 1::0-1::F
```

KeyID

Indicates that the *authid* value is an opaque byte stream. This identity type is intended for use with pre-shared key authentication. The ID value can be specified as an ASCII string, an EBCDIC string, or a hexadecimal string. The maximum length for an ASCII or EBCDIC string is 900 characters. The maximum length for a hexadecimal string is 450 bytes. The hexstring must begin with a 0x.

Examples:

KeyID Ascii SharedKeyValue

The value is treated as an ASCII string. This specification is valuable if the key ID is defined to the other endpoint as an ASCII string.

KeyID EbcDic SharedKeyValue

The value is treated as an EBCDIC string.

KeyID Hex 0xC1C2C3F1F2F3

The value is treated as a hexadecimal string.

The ASCII or EBCDIC KeyID value can be defined as a quoted string or a single value.

Rules:

- A quoted string must start and end with a double-quote (").
- A quoted string allows the KeyID value to have embedded blanks for the attribute.
- If KeyID value is not a quoted string then it is treated as a single value.

Results:

- Leading blanks and trailing blanks within the quoted string are removed.
- Within a quoted string, comment indicators, embedded blanks, and additional quotes are treated as part of the value for this attribute.

Restriction: This value is valid only for V1R12 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details

Restriction: When the value contains embedded blanks, you must specify the entire parameter value within the first 1 536 characters of the configuration file line.

Example KeyID values:

Identity	KeyID	Ascii	ASC # comment"	value used:	ASC
Identity	KeyID	EBCDIC	EBC comment	value used:	EBC
Identity	KeyID	ASCII	"ASC 98Z"	value used:	ASC 98Z
Identity	KeyID	EBCDIC	EBC 98Z"	value used:	EBC
Identity	KeyID	ASCII	"AsC 98Z	value used:	"AsC
Identity	KeyID	EBCDIC	"Ebc " " Ebc"	value used:	Ebc " " Ebc
Identity	KeyID	ASCII	"Asc Asc" "	value used:	Asc Asc"

Fqdn

Indicates that the *authid* value is a fully qualified domain name or host name. For example, vnet.ibm.com. The maximum length accepted is 1024 characters. The Fqdn value cannot begin or end with a dot (.), or contain consecutive dots.

The fqdn value can be wildcarded in the leftmost portion preceding the first period. For example, *.ibm.com is allowed.

The leftmost portion cannot be partially wildcarded. For example, *net.ibm.com is not allowed.

UserAtFqdn

Indicates that the *authid* value is a user at a fully qualified domain name or host name. The user name cannot contain a blank.

For example, ibm@vnet.ibm.com. The maximum length accepted is 1024 characters. The UserAtFqdn value cannot begin or end with a dot (.), or contain consecutive dots.

The user portion can be wildcarded. For example, *@vnet.ibm.com. Alternatively, the leftmost portion of the fqdn can be wildcarded. For example, *.ibm.com

X500dn

Indicates that the *authid* value is an X.500 distinguished name (DN). See [“LocalSecurityEndpoint statement”](#) on page 1055 for the DN specification.

The leftmost portion of the DN can be wildcarded. For example, *,OU=endicott,O=ibm,C=US is allowed.

Non-initial RDNs cannot be wildcarded. For example, CN="John Doe";*,O=ibm,C=US is not allowed.

Rule: You can use comment indicators and embedded blanks as part of the value for this attribute. For example:

```
Identity X500DN cn=#my identity
value used: cn=#my identity
```

Restriction: When the value contains embedded blanks, you must specify the entire parameter value within the first 1 536 characters of the configuration file line.

RemoteIdentityRef

The name of a globally defined RemoteIdentity statement that indicates the identity of a remote security endpoint with which dynamic VPN tunnel negotiations should be allowed.

Restriction: This parameter is valid only for V1R10 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details.

Location

ipaddress

A single IP address specification of a remote security endpoint with which dynamic VPN tunnel negotiations should be allowed.

Rule: The IPv6 unspecified address (::0) is not allowed.

ipaddress/prefixLength

A prefix address specification of a range of acceptable remote security endpoint IP addresses. The *prefixLength* value is the number of unmasked leading bits in the specified IP address and can have a value in the range 0 - 32 for IPv4 addresses and from 0 - 128 for IPv6 addresses.

Rule: The IPv6 unspecified address (::0/128) is not allowed.

ipaddress-ipaddress

A range of IP address specifications of acceptable remote security endpoint addresses for dynamic VPN tunnel negotiations.

Rule: The IPv6 unspecified address (::0-::0) is not allowed.

Any

Specifies all IPv4 addresses. **Any** and **Any4** are interchangeable values.

Any4

Specifies all IPv4 addresses.

Any6

Specifies all IPv6 addresses.

Result: If RemoteSecurityEndpoint is configured then the default value is set to **Any4**.

LocationRef

The name of a globally defined IPAddr statement for the remote security endpoint with which dynamic VPN tunnel negotiations should be allowed.

LocationSetRef

The name of a globally defined IPAddrSet statement for the remote security endpoint set with which dynamic VPN tunnel negotiations should be allowed.

LocationGroupRef

The name of a globally defined IPAddrGroup statement for the remote security endpoint group with which dynamic VPN tunnel negotiations should be allowed.

Restrictions:

- You cannot specify a group of IP addresses for a remote security endpoint that is referenced by an `IpLocalStartAction` statement.
- This parameter is valid only for V1R10 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details.

CaLabel

Use `CaLabel` to indicate which certificate authority the remote security endpoint should use when sending a certificate. Multiple instances of this keyword are permitted, indicating that there may be more than one acceptable certificate authority. The remote security endpoint may choose not to honor the request, in which case the negotiation may fail.

label

A label identifying a portion of a certificate authority hierarchy.

Rule: When IKED is configured to use local certificate services the label specified on the `CaLabel` parameter must be the label of a certificate authority certificate on the IKE servers key ring. This label must also be specified on the `SupportedCertAuth` parameter of the `IkeConfig` statement. See the description of `SupportedCertAuth` parameter in [“IkeConfig statement”](#) on page 387 for more information. This label identifies a specific certificate authority that the local security endpoint prefers. For example, consider a certificate hierarchy that consists of a Root CA, a subordinate CA X created by the Root CA, and a subordinate CA Y created by CA X.

- If the peers certificate should only be issued by the CA Y, then a `CaLabel` parameter with the label CA Y should be specified.
- If it is acceptable for the peers certificate to be issued by the CA Y or CA X, then a `CaLabel` parameter with label CA Y and a second `CaLabel` parameter with label CA X should be specified.
- If it is acceptable for the peers certificate to be issued by the Root CA, CA Y or CA X, then multiple `CaLabel` parameters should be specified, one for each of the acceptable certificate authorities.

Result: When IKED is configured to use local certificate services and no `CaLabel` parameters are specified, the `SupportedCertAuth` parameter on the `IkeConfig` statement provides the list of acceptable certificate authorities that the remote security endpoint should use. See the description of `SupportedCertAuth` parameter in [“IkeConfig statement”](#) on page 387 for more information.

Rule: When IKED is configured to use the Network Security Server's certificate services the label specified on the `CaLabel` parameter must be the label of a certificate authority certificate on the NSSD servers key ring and the stack must be authorized to the `EZB.NSSCERT.sysname.mappedlabelname.CERTAUTH` profile. This label identifies the start of a sub-hierarchy that the local security endpoint prefers. For example, consider a certificate hierarchy that consists of a Root CA, a subordinate CA X created by the root CA, and a subordinate CA Y created by CA X.

- If the peers certificate should only be issued by CA Y then a `CaLabel` parameter with the label of CA Y should be specified.
- If it is acceptable for the peers certificate to be issued by CA Y or CA X then only a `CaLabel` parameter with the label of CA X would need to be specified.
- If it is acceptable for the peers certificate to be issued by the Root CA, CA Y or CA X then only a `CaLabel` parameter with the label of the Root CA would need to be specified.

Result: When IKED is configured to use the Network Security Servers certificate services and no `CaLabel` parameters are specified, any certificate authority that has a certificate authority certificate on the NSSD keyring to which the stack is authorized is acceptable for the remote security endpoint to use. The `EZB.NSSCERT.sysname.mappedlabelname.CERTAUTH` profile is used to authorize a stack to a certificate authority certificate.

Rule: Comment indicators and embedded blanks are treated as part of the value for this attribute. For example:

```
CaLabel Root#CA Certificate
value used: Root#CA Certificate
```

Restriction: When the value contains embedded blanks, you must specify the entire value within the first 1 536 characters of the configuration file line.

Policy-based routing policy statements

This topic contains information about the following Routing policy statements:

- “RouteTable statement” on page 1068
- “RoutingAction statement” on page 1078
- “RoutingRule statement” on page 1079

For an example of Routing policy definitions see the pagent_routing.conf file in the /usr/lpp/tcpip/samples/ directory.

RouteTable statement

Use the RouteTable statement to create a table of the routes that can be used to route IP packets based on policy. A RoutingRule statement specifies the characteristics of IP packets and references a RoutingAction statement, which can reference one or more RouteTable statements.

The RouteTable statement is used to create a table of static and dynamic routes. The RouteTable statement is made up of Route entries and DynamicRoutingParms entries. A route entry is used to create a static route in the route table. The syntax for the route entry is compatible with UNIX standards and similar to the syntax for static routes in the TCP/IP profile's BEGINROUTES block. Dynamic routes are added to the route table by OMPROUTE based on the information provided in DynamicRoutingParms entries. IPv6 router advertisement routes are also added to the route table based on the information that is provided in the DynamicRoutingParms entries.

Restrictions:

- A limit of 255 route tables is allowed.
- Duplicate RouteTableRef parameters are not allowed within a RoutingAction statement

The route table can be modified as follows:

- Incoming ICMP and ICMPv6 redirect packets can replace static routes, and can also add routes to the route table.
- The OMPROUTE dynamic routing daemon can replace replaceable static routes, and can add dynamic routes to the route table.
- IPv6 router advertisement routes can be added to the route table based on received IPv6 router advertisements, and can replace replaceable static routes.
- Direct host routes to dynamic XCF addresses on other TCP/IP stacks are added when both of the following conditions are true:
 - The dynamic XCF links to those stacks are active.
 - DynamicXCFRoutes Yes or DynamicXCFRoutes6 Yes is specified on the RouteTable statement.

When a RouteTable statement is updated, the route table in the TCP/IP stack is updated. When a route entry is added, deleted, or updated, the static routes in the route table are updated and routes learned by way of ICMP or ICMPv6 redirect are deleted from the route table. When a DynamicRoutingParms entry is added, deleted, or updated, OMPROUTE updates the dynamic routes in the route table as needed, and any IPv6 router advertisement routes in the route table are updated as needed.

Route precedence is as follows:

1. If a route exists to the destination address (a host route), it is chosen first.
2. For IPv4, if subnet, network, or supernet routes exist to the destination, the route with the most specific network mask is chosen second. The most specific network mask is the mask with the most bits on. For IPv6, if prefix routes exist to the destination, the route with the most specific prefix is chosen second.
3. For IPv4, if the destination is a multicast destination and multicast default routes exist, the route with the most specific multicast address is chosen third.
4. Default routes are chosen when no other route exists to a destination.

Rules:

- The RouteTable statement must contain at least one Route entry or one DynamicRoutingParms entry; otherwise, you must specify either DynamicXCFRoutes Yes or DynamicXCFRoutes6 Yes.
- The required parameters for the route entry must be specified in the order shown. The optional parameters can be specified in any order.
- The parameters for the DynamicRoutingParms entry must be specified in the order shown.

Tip: The Options parameters on the route entry can be abbreviated using the same syntax that is used for static routes in the TCP/IP profile's BEGINROUTES block.

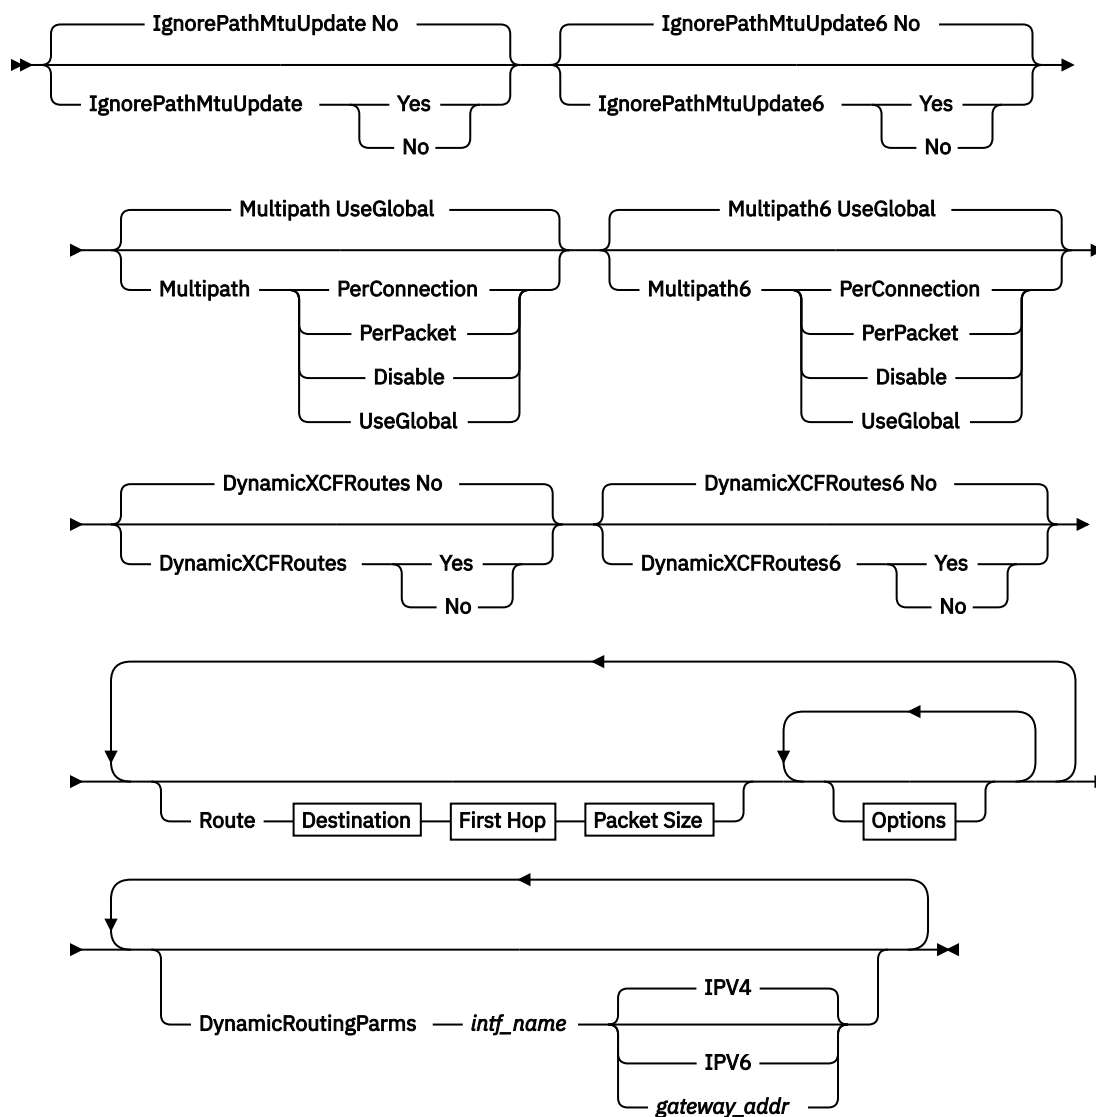

Syntax

►► RouteTable — *name* — Put Braces and Parameters on Separate Lines ◄◄

Put Braces and Parameters on Separate Lines

RouteTable Parameters

Destination

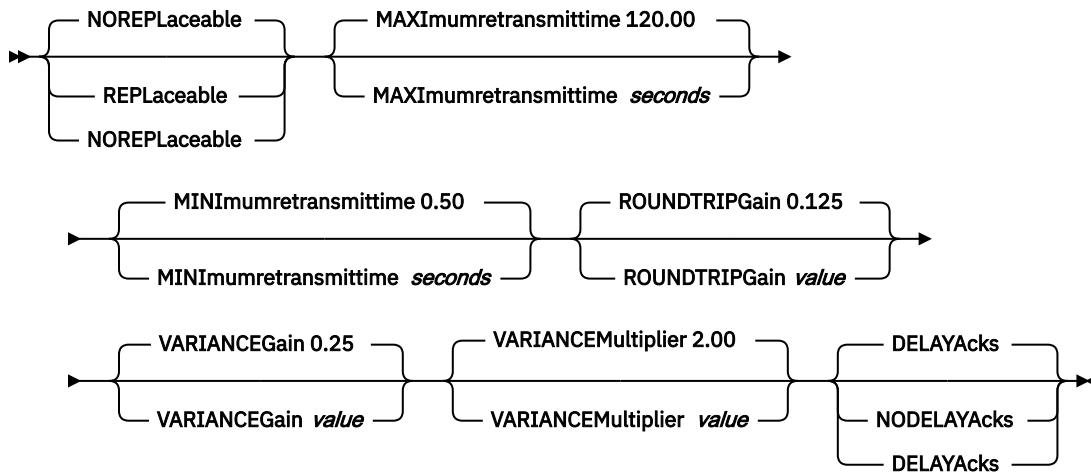

First Hop

Packet Size

Options

Parameters

name

A string 1 - 8 characters in length specifying the name of this RouteTable statement.

Restriction: Do not specify the values EZBMAIN or ALL (in any combination of upper and lower case letters) for the name value. The name EZBMAIN is reserved for the main route table that is generated by the TCP/IP profile's BEGINROUTES or GATEWAY statements. The name ALL is reserved for use with the PR modifier of the Netstat ROUTE/-r command.

IgnorePathMtuUpdate

Indicates whether IPv4 ICMP Fragmentation Needed messages should be ignored for this route table. When IPv4 path MTU discovery is enabled (PATHMTUDISCOVERY parameter on the IPCONFIG statement in the TCP/IP profile), IPv4 ICMP Fragmentation Needed messages are used to lower the MTU value that is used to send data to a specific IPv4 destination.

No

IPv4 ICMP Fragmentation Needed messages should be processed for this route table. This is the default.

Yes

IPv4 ICMP Fragmentation Needed messages should be ignored for this route table.

You might want to ignore the path MTU update for a policy-based route table that contains routes that are known to support large path MTU values. If routes in another route table are defined to the same destination or destinations that need a smaller path MTU value, specifying IgnorePathMtuUpdate Yes ensures that a path MTU update that is the result of sending data on a small MTU route does not cause an update to the path MTU for the route in the policy-based route table.

Guideline: The IgnorePathMtuUpdate option is an advanced option. You do not need to set IgnorePathMtuUpdate Yes. If you specify IgnorePathMtuUpdate Yes, path MTU updates are ignored for all IPv4 routes in the route table.

IgnorePathMtuUpdate6

Indicates whether IPv6 ICMP Packet Too Big messages should be ignored for this route table. IPv6 ICMP Packet Too Big messages are used to lower the MTU value that is used to send data to a specific IPv6 destination.

No

IPv6 ICMP Packet Too Big messages should be processed for this route table. This is the default.

Yes

IPv6 ICMP Packet Too Big messages should be ignored for this route table.

You might want to ignore the path MTU update for a policy-based route table that contains routes that are known to support large path MTU values. If routes in another route table are defined to the same destination or destinations that need a smaller path MTU value, specifying IgnorePathMtuUpdate6 Yes ensures that a path MTU update that is the result of sending data on a small MTU route does not cause an update to the path MTU for the route in the policy-based route table.

Guideline: The IgnorePathMtuUpdate6 option is an advanced option. You do not need to set IgnorePathMtuUpdate6 Yes. If you specify IgnorePathMtuUpdate6 Yes, path MTU updates are ignored for all IPv6 routes in the route table.

Multipath

Indicates whether the multipath routing selection algorithm is enabled for outbound IPv4 traffic that uses this policy-based route table.

UseGlobal

Use the MULTIPATH or NOMULTIPATH setting from the IPCONFIG statement in the TCP/IP profile to determine multipath processing. This is the default.

PerConnection

Enables the multipath routing selection algorithm for outbound IPv4 traffic that uses this policy-based route table. If multiple equal-cost routes to an IPv4 destination exist in this policy-based route table, a round-robin algorithm is used to select a route. After a route is selected, connection-oriented or connectionless-oriented IP packets using the same association always use the same route, as long as that route is active.

PerPacket

Enables the multipath routing selection algorithm for outbound IPv4 traffic that uses this policy-based route table. If multiple equal-cost routes to an IPv4 destination exist in this policy-based route table, a round-robin algorithm is used to select a route. Connection or connectionless oriented IP packets using the same association do not always use the same route, but do use all possible active routes to the destination.

The PerPacket option should not be used if IP security is enabled on the IPCONFIG statement in the TCP/IP profile. If Multipath PerPacket is specified for a policy-based route table and the route table is installed in a TCP/IP stack with IPv4 security enabled, multipath routing for IPv4 traffic is disabled. The following message is displayed: EZD0028I IPV4 MULTIPATH PERPACKET NOT VALID WITH IPV4 SECURITY - MULTIPATH SUPPORT DISABLED FOR ROUTE TABLE

The Netstat ROUTE/-r PR command displays the MultiPath setting No(Policy) if multipath routing for IPv4 traffic has been disabled. This occurs because IPv4 security is enabled.

Disable

Disables the multipath routing selection algorithm for outbound IPv4 traffic that uses this policy-based route table. If multiple equal-cost routes to an IPv4 destination exist in this policy-based route table, the first active route that is found is used to send each IP packet to that destination.

Multipath6

Indicates whether the multipath routing selection algorithm is enabled for outbound IPv6 traffic that uses this policy-based route table.

UseGlobal

Uses the MULTIPATH or NOMULTIPATH setting from the IPCONFIG6 statement in the TCP/IP profile to determine multipath processing. This is the default.

PerConnection

Enables the multipath routing selection algorithm for outbound IPv6 traffic that uses this policy-based route table. If multiple equal-cost routes to an IPv6 destination exist in this policy-based route table, a round-robin algorithm is used to select a route. After a route is selected, connection-oriented or connectionless-oriented IP packets that use the same association always use the same route, as long as that route is active.

PerPacket

Enables the multipath routing selection algorithm for outbound IPv6 traffic that uses this policy-based route table. If multiple equal-cost routes to an IPV6 destination exist in this policy-based route table, a round-robin algorithm is used to select a route. Connection-oriented or connectionless-oriented IP packets that use the same association do not always use the same route, but use all possible active routes to the destination.

If IP security is enabled on the IPCONFIG6 statement in the TCP/IP profile, do not use the PerPacket option. If Multipath6 PerPacket is specified for a policy-based route table and the route table is installed in a TCP/IP stack with IPv6 security enabled, multipath routing for IPv6 traffic is disabled. The following message is displayed: EZD0028I IPV6 MULTIPATH PERPACKET NOT VALID WITH IPV6 SECURITY - MULTIPATH SUPPORT DISABLED FOR ROUTE TABLE

The Netstat ROUTE/-r PR command displays the MultiPath6 setting No(Policy) if multipath routing for IPv6 traffic has been disabled. This occurs because IPv6 security is enabled.

Disable

Disables the multipath routing selection algorithm for outbound IPv6 traffic that uses this policy-based route table. If multiple equal-cost routes to an IPv6 destination exist in this policy-based route table, the first active route that is found is used to send each IP packet to that destination.

DynamicXCFRoutes

Indicates whether direct routes to IPv4 dynamic XCF addresses on other TCP/IP stacks should be added to this route table. The same routes are automatically generated in the main route table when IPv4 dynamic XCF links are active. See the dynamic XCF information in [z/OS Communications Server: IP Configuration Guide](#) for information about the dynamic XCF function and the definitions that are automatically generated when IPCONFIG DYNAMICXCF is specified in the TCP/IP profile.

Yes

Add direct routes to IPv4 dynamic XCF addresses on other TCP/IP stacks when the dynamic XCF links are active.

No

Do not add direct routes to IPv4 dynamic XCF addresses on other TCP/IP stacks. This is the default.

Rule: Duplicate routes are not allowed within a route table. If a statically defined route is a duplicate of a route generated by DynamicXCFRoutes Yes, the statically defined route takes precedence.

DynamicXCFRoutes6

Indicates whether direct routes to IPv6 dynamic XCF addresses on other TCP/IP stacks should be added to this route table. The same routes are automatically generated in the main route table when IPv6 dynamic XCF links are active. See the dynamic XCF information in [z/OS Communications Server: IP Configuration Guide](#) for information about the dynamic XCF function and the definitions that are automatically generated when IPCONFIG6 DYNAMICXCF is specified in the TCP/IP profile.

Yes

Add direct routes to IPv6 dynamic XCF addresses on other TCP/IP stacks when the dynamic XCF links are active.

No

Do not add direct routes to IPv6 dynamic XCF addresses on other TCP/IP stacks. This is the default.

Rule: Duplicate routes are not allowed within a route table. If a statically defined route is a duplicate of a route that the DynamicXCFRoutes6 Yes generates, the statically defined route takes precedence.

Route

A route entry is used to create a static route in the route table.

Restriction: Duplicate routes are not allowed within a RouteTable statement. Duplicate routes have the same destination and first hop specification (interface name and gateway address).

DynamicRoutingParms

A DynamicRoutingParms entry provides parameters for OMROUTE to use when generating dynamic routes for the route table and for the stack to use when adding IPv6 router advertisement routes to the route table.

Restriction: Duplicate and overlapping DynamicRoutingParms values are not allowed within a RouteTable statement.

In the following example, the DynamicRoutingParms in both Table1 and Table2 are treated as routing policy errors because the DynamicRoutingParms values overlap:

```
RouteTable Table1
{
  DynamicRoutingParms Link1
  DynamicRoutingParms Link1 10.1.2.3
}
```

```
RouteTable Table2
{
  DynamicRoutingParms Link2 IPv6
  DynamicRoutingParms Link2 FE80::1:2:3
}
```

In the following example, the DynamicRoutingParms in both Table3 and Table4 are treated as Routing policy errors because the DynamicRoutingParms values are duplicates.

```
RouteTable Table3
{
  DynamicRoutingParms Link1
  DynamicRoutingParms Link1
}
RouteTable Table4
{
  DynamicRoutingParms Link2 FE80::1:2:3
  DynamicRoutingParms Link2 FE80::1:2:3
}
```

ipaddress

The destination address. The address must be a fully qualified IP address.

The DEFAULT or DEFAULT6 keyword in this field specifies a default route. The destination address can be a host, network, subnetwork, supernetwork, or default address. For IPv6, the address cannot be an IPv4-mapped IPv6 address in hexadecimal or dotted decimal format or an IP address with the reserved prefix `::/96`. A local address is not valid for the destination address. Multiple routes that have an identical destination can be specified. When multiple routes are specified, all of them are used when multipath is enabled; otherwise, only the first active route that is specified is used.

prefixLength

An integer value that represents the number of bits in the *ipaddress* value that are used to determine the destination address of the route. For an IPv4 destination, the value is in the range 1 - 32. For an IPv6 destination, the value is in the range 1 - 128.

gateway_addr

On a route entry, the *gateway_addr* value is the host IP address of a gateway or router that you can reach directly, and that forwards packets for the destination network or host. The value must be either a fully qualified address or an equal sign (=), which indicates that the messages are routed directly to destinations on that network or directly to that host. A local address is not valid for the gateway address. The equal sign is not supported for a default route entry. For IPv6, the address cannot be an IPv4-mapped IPv6 address in hexadecimal or dotted decimal format or an IP address with the reserved prefix `::/96`.

On a DynamicRoutingParms entry, the *gateway_addr* value is one of the following values:

- IPv4

Indicates that the *intf_name* value that is specified on this DynamicRoutingParms entry is an IPv4 interface. This is the default.

- IPv6

Indicates that the *intf_name* value that is specified on this DynamicRoutingParms entry is an IPv6 interface.

- The host IP address of a gateway or router that you can reach directly, and that forwards packets for the destination network or host.

It must be a fully qualified address. A local address is not valid for the gateway address. If an IPv6 address is specified, it must be a link-local address. OMPROUTE uses the IP address and the *intf_name* value to select dynamic routes to be included in this route table. If the *gateway_addr* value is an IPv6 address, the value is used with the *intf_name* value to determine which IPv6 router advertisement routes are added to this route table.

intf_name

The name of an interface as defined on the LINK or INTERFACE statement in the TCP/IP profile.

Restriction: Loopback and VIPA links are not allowed.

On a route entry, the *intf_name* value is the name of the interface through which packets are sent to the specified destination. If an *intf_name* value is specified that is not defined in the TCP/IP profile, the route is created but is not usable until that interface value is defined in the TCP/IP profile.

Tip: Routes that are configured for an undefined interface name are flagged as invalid on a Netstat ROUTE/-r PR display. The flags field includes the letter I.

On a DynamicRoutingParms entry, the *intf_name* value is the name of an interface through which packets can be sent. OMPROUTE uses the *intf_name* value to select dynamic routes to be included in this route table. If *intf_name* is the name of an IPv6 interface, the value is used to determine which IPv6 router advertisement routes are added to this route table. If *gateway_addr* has been specified, then *intf_name* is used in combination with the *gateway_addr* value. If an interface name is specified that is not defined in the TCP/IP profile, no dynamic routes or IPv6 router advertisement routes are created until the interface name is defined in the TCP/IP profile.

MTU *mtu_size*

The maximum transmission unit (MTU) in bytes for the destination. This value can be up to 65535. The keyword DEFAULTSIZE in this field requests that TCP/IP supply a default value of 576 for IPv4 routes and 1280 for IPv6 routes.

See [Figure 1 on page 36](#) for more information about the largest MTU value that each IPv4 link type supports.

See [Table 5 on page 80](#) for more information about the largest MTU value that each IPv4 interface type supports.

See [Table 6 on page 81](#) for more information about the largest MTU value that each IPv6 interface type supports.

Packet size considerations

- The largest *mtu_size* value that z/OS Communications Server can handle varies for different networks. For example, although the largest packet size for the Ethernet protocol is 1500 bytes, the largest packet size for the 802.3 protocol is 1492 bytes.
- The actual packet size is determined by the total network connection.
 - If a locally attached host has a packet size smaller than your packet size, transfers to that host use the smaller size.
 - The TCP maximum segment size for the 3172 Interconnect Controller Program is 4096. Any packet specifications over 4096 are limited by this restriction. For example, if you specified the packet size 4352, the resulting packet size would still only be 4096 plus the header size, for a total packet size of 4132.
- Large packets can be fragmented by intervening gateways for IPv4 only. Fragmenting and reassembling packets is expensive because of high bandwidth use and CPU time. Packets sent

through gateways to other networks should use the default size, DEFAULTSIZE, unless one of the following conditions is true:

- All intervening gateways and networks are known to accept larger packets.
- IPv4 Path MTU discovery is enabled by using PATHMTUDISCOVERY on the IPCONFIG statement, which results in the TCP/IP stack dynamically learning the maximum MTU for the total network connection. For IPv6, Path MTU discovery is always enabled.
- You cannot specify an MTU value that is smaller than the default MTU size. For IPv4, the default MTU value is 576 and for IPv6 it is 1280.

REPLACEABLE

Indicates that the static route can be replaced by OMPROUTE or IPv6 router advertisements if a dynamic route to the same destination is discovered. This parameter can be abbreviated to REPL.

Restrictions:

- Only one type (replaceable or nonreplaceable) of static route can be defined to the same destination. If multiple route entries are specified to the same destination and the REPLACEABLE or NOREPLACEABLE setting is not the same, it is considered to be a Routing policy error.
- Do not define replaceable static routes to destination addresses that correspond to dynamic VIPAs for which the TCP/IP stack is a sysplex distributor target. This is not validated by Policy Agent.

Tip: You can use the Netstat ROUTE/-r PR ALL RSTAT command to display all replaceable static routes currently configured in policy-based routing tables.

NOREPLACEABLE

Indicates that the static route cannot be replaced by dynamic routes. The static route is always used to reach the destination, regardless of any information that dynamic routes might be available. This is the default behavior. This parameter can be abbreviated NOREPL.

Restriction: Only one type (replaceable or nonreplaceable) of static route can be defined to the same destination. If multiple route entries are specified to the same destination and the REPLACEABLE or NOREPLACEABLE setting is not the same, it is considered to be a Routing policy error.

Retransmission parameter considerations

The parameters listed in this topic affect the TCP retransmit algorithms. When TCP packets are not acknowledged, TCP begins to retransmit these packets at certain time intervals. If these packets are not acknowledged after a specified number of retransmits, TCP aborts the connection. The time interval between retransmissions increases by approximately twice the previous interval until the packets are acknowledged or the connection times out.

The time intervals between retransmissions and the number of times that packets are retransmitted before the connection times out differs for initial connection establishment and for data packets. For initial connection establishment, the initial time interval is set at approximately 3 seconds and the SYN packet is retransmitted 5 times before the connection is timed out. Data packets use a smoothed Round Trip Time (RTT) as the initial time interval, and data packets are retransmitted 15 times before the connection is timed out. All of the remaining parameters listed in this topic affect the data packet retransmission algorithm. Only the MINIMUMRETRANSMITTIME parameter affects the initial connection establishment.

Tip: A new route lookup is performed after every two retransmissions for a data packet. For more information about the route lookup process, see [Route selection algorithm in z/OS Communications Server: IP Configuration Guide](#). Be careful when you design networks with firewalls. A firewall in an alternate routing path can generate a RESET packet for the rerouted data packets, which causes TCP to abort the connection.

The retransmission parameters enable system administrators who are familiar with TCP/IP transmission performance to alter the flow of TCP/IP data packets and acknowledgments. Under normal circumstances, the following occurs:

- TCP typically waits to receive two packets before sending one ACK to acknowledge the data within them.
- When TCP sends a packet, it waits for an acknowledgment. If it times out before getting an acknowledgment, it resends the packet.

Use the following parameters to adjust the retransmission time-out calculations; slower transmission times prevent packets from being resent as quickly:

- MAXIMUMRETRANSMITTIME
- MINIMUMRETRANSMITTIME
- ROUNDTRIPGAIN
- VARIANCEGAIN
- VARIANCEMULTIPLIER
- DELAYACKS
- NODELAYACKS

TCP uses these values in an algorithm called the TCP Retransmission Timeout Calculation, which is described in RFC 793. When you use this calculation, the following occurs:

- A smoothed round trip time (SRTT) and variance (VAR) is updated from the individual RTT derived from each packet acknowledgement.
- The retransmit time for a new packet is set to twice (approximately) the current SRTT value plus the VAR value.
- Each time a packet is retransmitted, the retransmit time value is doubled.
- The actual interval time used for the initial packet and each retransmission is the retransmit time calculated previously, but limited by the configured MINIMUMRETRANSMITTIME and MAXIMUMRETRANSMITTIME values.

DELAYACKS | NODELAYACKS

Controls transmission of acknowledgments when a packet is received with the PUSH bit on in the TCP header.

NODELAYACKS

Specifies that an acknowledgment is returned immediately when a packet is received with the PUSH bit on in the TCP header. The NODELAYACKS parameter on the BEGINROUTES, GATEWAY, and RouteTable statements affects only the connections that use this route. Specifying NODELAYACKS on the TCP/IP stack BEGINROUTES or GATEWAY profile statements, or on the Policy Agent RouteTable statement, overrides the specification of the DELAYACKS parameter on the TCP/IP stack PORT, PORTRANGE, and TCPCONFIG profile statements.

DELAYACKS

Delays transmission of acknowledgments when a packet is received with the PUSH bit on in the TCP header. The DELAYACKS parameter on the BEGINROUTES, GATEWAY, and RouteTable statements affects only the connections that use this route. This is the default, but you can override the default by specifying the NODELAYACKS parameter on the TCP/IP stack PORT, PORTRANGE, or TCPCONFIG profile statements.

MAXIMUMRETRANSMITTIME

Limits the TCP retransmission interval. Decreasing this value might decrease the total time it takes a connection to timeout. Specifying MAXIMUMRETRANSMITTIME assures that the interval time never exceeds the specified limit. The minimum value that can be specified for MAXIMUMRETRANSMITTIME is 0. The maximum is 999.990. The default is 120 seconds. This parameter does not affect initial connection retransmission.

MINIMUMRETRANSMITTIME

Sets a minimum retransmit interval. Increasing this value might increase the amount of time it takes for TCP to time out a connection. The minimum value that can be specified for MINIMUMRETRANSMITTIME is 0. The maximum is 99.990. The default is 0.5 (500 milliseconds).

ROUNDTRIPGAIN

This value is the percentage of the latest Round Trip Time (RTT) to be applied to the smoothed RTT average. The higher this value, the more influence the latest packet RTT has on the average. The minimum value that can be specified for ROUNDTRIPGAIN is 0. The maximum value is 1.0. The default is 0.125. This parameter does not affect initial connection retransmission.

VARIANCEGAIN

This value is the percentage of the latest RTT variance from the RTT average to be applied to the RTT variance average. The higher this value, the more influence the latest packet's RTT has on the variance average. The minimum value that can be specified for VARIANCEGAIN is 0. The maximum value is 1.0. The default is 0.25. This parameter does not affect initial connection retransmission.

VARIANCEMULTIPLIER

This value is multiplied against the RTT variance in calculating the retransmission interval. The higher this value, the more affect variation in RTT has on calculating the retransmission interval. The minimum value that can be specified for VARIANCEMULTIPLIER is 0. The maximum value is 99.990. The default is 2. This parameter does not affect initial connection retransmission.

Retransmission parameters

Use the ROUNDTRIPGAIN, VARIANCEGAIN, and VARIANCEMULTIPLIER parameters to instruct TCP how heavily to weigh the most recent behavior of the network versus the long term behavior for updating the SRTT and VAR values. If you specify smaller values for these parameters, TCP attempts to correct for congestion only if the congestion is sustained. With larger values, TCP corrects for congestion more quickly, and the system is more sensitive to variations in network performance. Use the default values (unless your retransmission rate is too high).

Use DELAYACKS to delay the acknowledgments so that they can be combined with data sent to the foreign host.

Results:

- If a HOME entry or INTERFACE is deleted from the TCP/IP profile, all routes for the associated interface become unusable. The routes remain in the route table and become usable again if the HOME entry or INTERFACE is added back to the profile.
- If an interface becomes inactive, then all routes that are associated with that interface are marked inactive by the stack.
- If an interface becomes active, then all static routes that are associated with that interface are marked active by the stack.

Rules:

- There is no limit to the number of equal-cost multipath routes that can be associated with a single destination.
- Multicast routes can be specified using a host specification. You can also specify multicast network routes or prefix routes.
- A valid host address must contain a nonzero value in the host portion of the address. The host portion of an IPv4 address cannot be all ones, which is considered the broadcast address.
- On an IPv4 route entry, the destination IP address can be either a network or a host IPv4 address, and the *gateway_addr* value must be a host IPv4 address.
- On an IPv6 route entry, the destination IP address can be either a prefix or host IPv6 address, and the *gateway_addr* value must be a host IPv6 address.

RoutingAction statement

Use the RoutingAction statement to provide an ordered list of RouteTable references and to specify whether the TCP/IP stack's main route table should be used if a usable route is not found in any of the referenced route tables. The stack's main route table is defined in the TCP/IP profile and updated

by dynamic routing protocols if configured to do so. A RoutingAction statement can be referenced by a RoutingRule statement.

►► RoutingAction — *name* — Put Braces and Parameters on Separate Lines ►►

Put Braces and Parameters on Separate Lines

RoutingAction Parameters

Parameters

name

A string 1 - 32 characters in length specifying the name of this RoutingAction statement.

UseMainRouteTable

Indicates the action taken by the stack when a usable route is not found in any of the referenced route tables.

Yes

When a usable route is not found in any of the referenced route tables, use the stack's main route table to look up a route. This is the default value.

No

When a usable route is not found in any of the referenced route tables, do not use the stack's main route table to look up a route. The packet is not routed.

RouteTableRef

The name of a globally defined RouteTable statement.

Restriction: Duplicate RouteTableRef parameters are not allowed in a RoutingAction statement.

Rules:

- If the UseMainRouteTable No value is specified, then at least one RouteTableRef parameter is required.
- A maximum of eight RouteTableRef parameters can be configured for a routing action. Route tables are searched in the order in which the RouteTableRef parameters are specified.

RoutingRule statement

Use the RoutingRule statement to specify characteristics of IP packets that are used to control the route over which the packets can be sent. The RoutingRule statement references a corresponding RoutingAction statement that indicates which route tables to search.

The information provided on the RoutingRule statement defines a routing rule. The routing rule can contain a source IP address, destination IP address, and traffic descriptor specification. The traffic descriptor specification identifies characteristics of IP packets in addition to the IP addresses (for example, source and destination ports). The routing rule can contain a priority and an IpTimeCondition statement specification. An IpTimeCondition statement specification identifies the time period during which the routing rule is in effect.

Restriction: Policy-based routing applies only to TCP and UDP traffic that originates at the TCP/IP stack. Traffic that uses protocols other than TCP and UDP and all traffic that the TCP/IP stack forwards are always routed by using the main route table, even when policy-based routing is in use.

Rules:

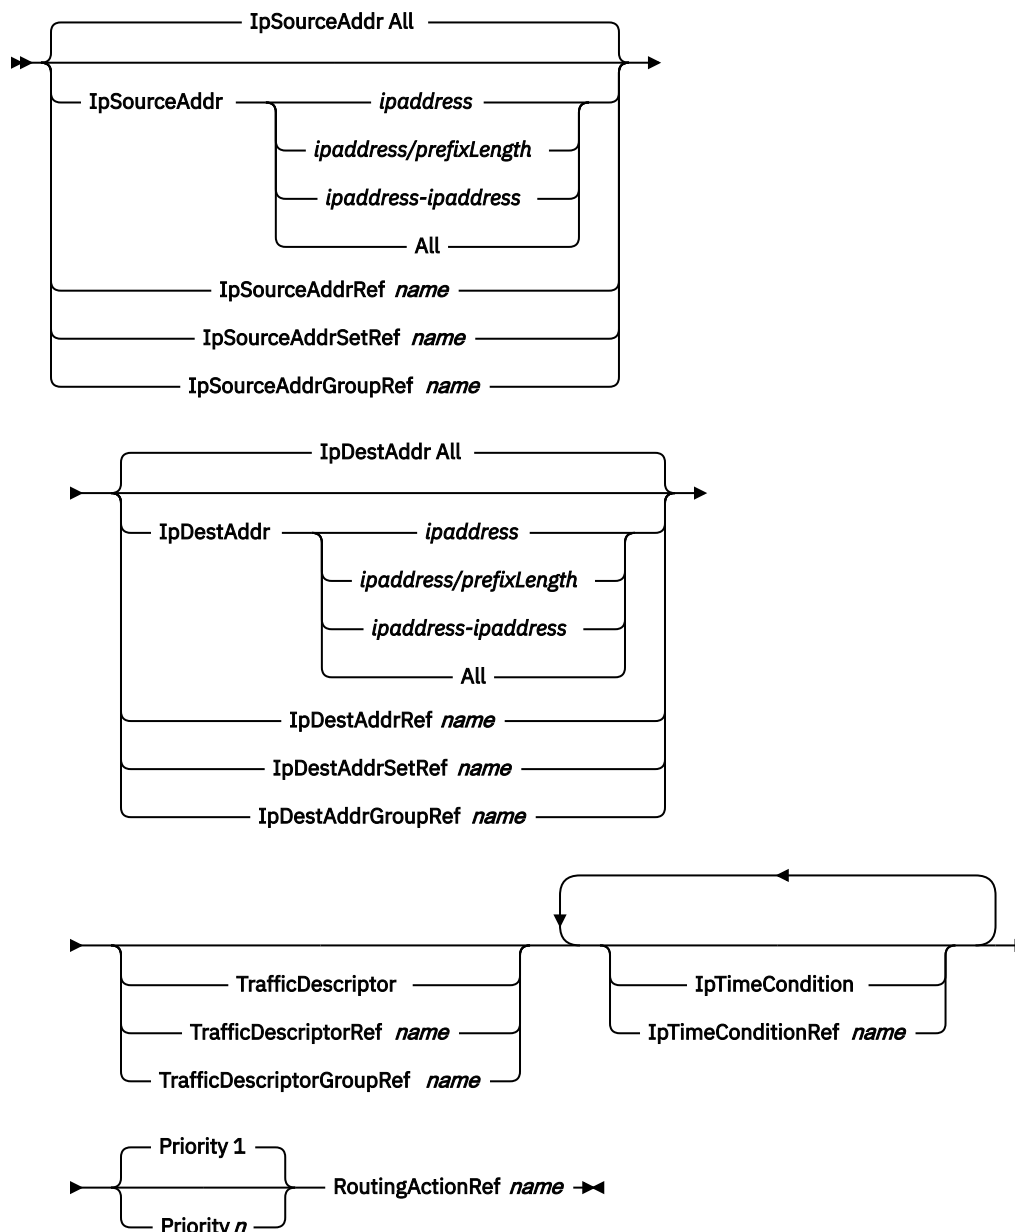

- A RoutingRule statement must contain a reference to a globally defined RoutingAction statement.
- If you use default values for the source IP address, destination IP address, and traffic descriptor specifications, the RoutingRule statement applies to all TCP and UDP traffic that originates from this TCP/IP stack.

►► RoutingRule — *name* — Put Braces and Parameters on Separate Lines ◄◄

Put Braces and Parameters on Separate Lines

RoutingRule Parameters

Parameters

name

A string 1 - 32 characters in length specifying the name of this RoutingRule statement.

IpSourceAddr

A source address in an outbound IP packet that matches this rule so that the action of the rule can be performed. The default value is All, which indicates that any source address matches this rule.

Guideline: The source IP address for a TCP outbound connection, or for a UDP outbound packet, can be influenced by a number of configuration and application options. See the [source IP selection](#) in *z/OS Communications Server: IP Configuration Guide* for the hierarchy of ways that the source IP address of an outbound packet is determined. For the following source IP address selection methods, a route lookup is needed to determine the source IP address:

- **SOURCEVIPA:** Static VIPA address from the HOME list (IPv4 interface defined with the LINK statement) or from the SOURCEVIPAINTERFACE parameter (IPv4 or IPv6 interface defined with the INTERFACE statement)

- HOME: IP address of the interface over which the packet is sent

Do not use the `IpSourceAddr` value to select traffic that relies on these methods to select its source IP address. At the time that route lookup is performed, the source IP address has not yet been selected.

All

Any source IP address matches this rule.

ipaddress

A single IP address.

ipaddress/prefixLength

A prefix address specification. The *prefixLength* value is the number of unmasked leading bits in the *ipaddress* value. The *prefixLength* value can be in the range 0 - 32 for IPv4 addresses and 0 - 128 for IPv6 addresses. An IP packet matches this condition if its unmasked bits are identical to the defined unmasked bits.

Results:

- 0.0.0.0/0 indicates that any IPv4 source address matches this rule.
- ::/0 indicates that any IPv6 source address matches this rule.

ipaddress-ipaddress

A range of IP addresses.

Restriction: If the IP address is an IPv6 address, it cannot be an IPv4-mapped IPv6 address in hexadecimal or dotted decimal format or an IP address with the reserved prefix `::/96`. If the IPv6 address is one of these types, an error message is logged.

IpSourceAddrRef

The name of a globally defined `IpAddr` statement that is used for the source IP address specification.

IpSourceAddrSetRef

The name of a globally defined `IpAddrSet` statement that is used for the source IP address prefix or range specification.

IpSourceAddrGroupRef

The name of a globally defined `IpAddrGroup` statement that is used for the source IP address specification.

IpDestAddr

A destination address in an outbound IP packet that matches this rule so that the action of the rule can be performed. The default is `All`, which indicates that any destination address matches this rule.

All

Any destination IP address matches this rule.

ipaddress

A destination IP address.

ipaddress/prefixLength

A prefix address specification. The *prefixLength* value is the number of unmasked leading bits in the *ipaddress* value. The *prefixLength* value can be in the range 0 - 32 for IPv4 addresses and 0 - 128 for IPv6 addresses. An IP packet matches this condition if its unmasked bits are identical to the defined unmasked bits.

Results:

- 0.0.0.0/0 indicates that any IPv4 destination address matches this rule.
- ::/0 indicates that any IPv6 destination address matches this rule.

ipaddress-ipaddress

A range of IP addresses.

Restriction: If the IP address is an IPv6 address, it cannot be an IPv4-mapped IPv6 address in hexadecimal or dotted decimal format or an IP address with the reserved prefix `::/96`. If the IPv6 address is one of these types, an error message is logged.

IpDestAddrRef

The name of a globally defined IpAddr statement that is used for the destination IP address specification.

IpDestAddrSetRef

The name of a globally defined IpAddrSet statement that is used for the destination IP address prefix or range specification.

IpDestAddrGroupRef

The name of a globally defined IpAddrGroup statement that is used for the destination IP address specification.

TrafficDescriptor

An inline specification of a TrafficDescriptor statement.

TrafficDescriptorRef

The name of a globally defined TrafficDescriptor statement.

TrafficDescriptorGroupRef

The name of a globally defined TrafficDescriptorGroup statement.

IpTimeCondition

An inline specification of an IpTimeCondition statement. There is a limit of 25 IpTimeCondition specifications in the RoutingRule statement.

IpTimeConditionRef

The name of a globally defined IpTimeCondition statement. There is a limit of 25 IpTimeCondition references in the RoutingRule statement.

Priority

This is an integer value in the range 1 - 2000000000 representing the priority associated with the rule.

Restriction: Only one rule is mapped to a route request. Rules are searched for a match starting at the highest priority, so if multiple rules could possibly be matched for a given route request, the rule with the highest priority gets matched first. If multiple rules of the same priority match, the rule mapped is difficult to predict. If this attribute is not specified, the default priority is 1.

Guideline: When setting the priority for multiple rules, do not set the priority as a sequential value, for example 2, 3, 4, and 5. Instead, set the priority to provide space to change the priority or to insert additional rules, such that the rule would be preferred before another rule, without duplicating a priority. For example, the priorities could be configured as 20, 30, 40, and 50.

RoutingActionRef

The name of a globally defined RoutingAction statement.

QoS policy statements

This topic contains information about the following QoS policy statements:

- [“PolicyAction statement” on page 1083](#)
- [“PolicyRule statement” on page 1090](#)
- [“ServiceCategories statement” on page 1097](#)
- [“ServicePolicyRules statement” on page 1101](#)

PolicyAction statement

Use the PolicyAction statement to specify the type of service a flow of IP packets (for example, from a TCP connection, or UDP data) should receive end-to-end as they traverse the network. PolicyAction can be repeated with each having a different name so that they can be referenced later.

This statement defines a Version 2 policy action.

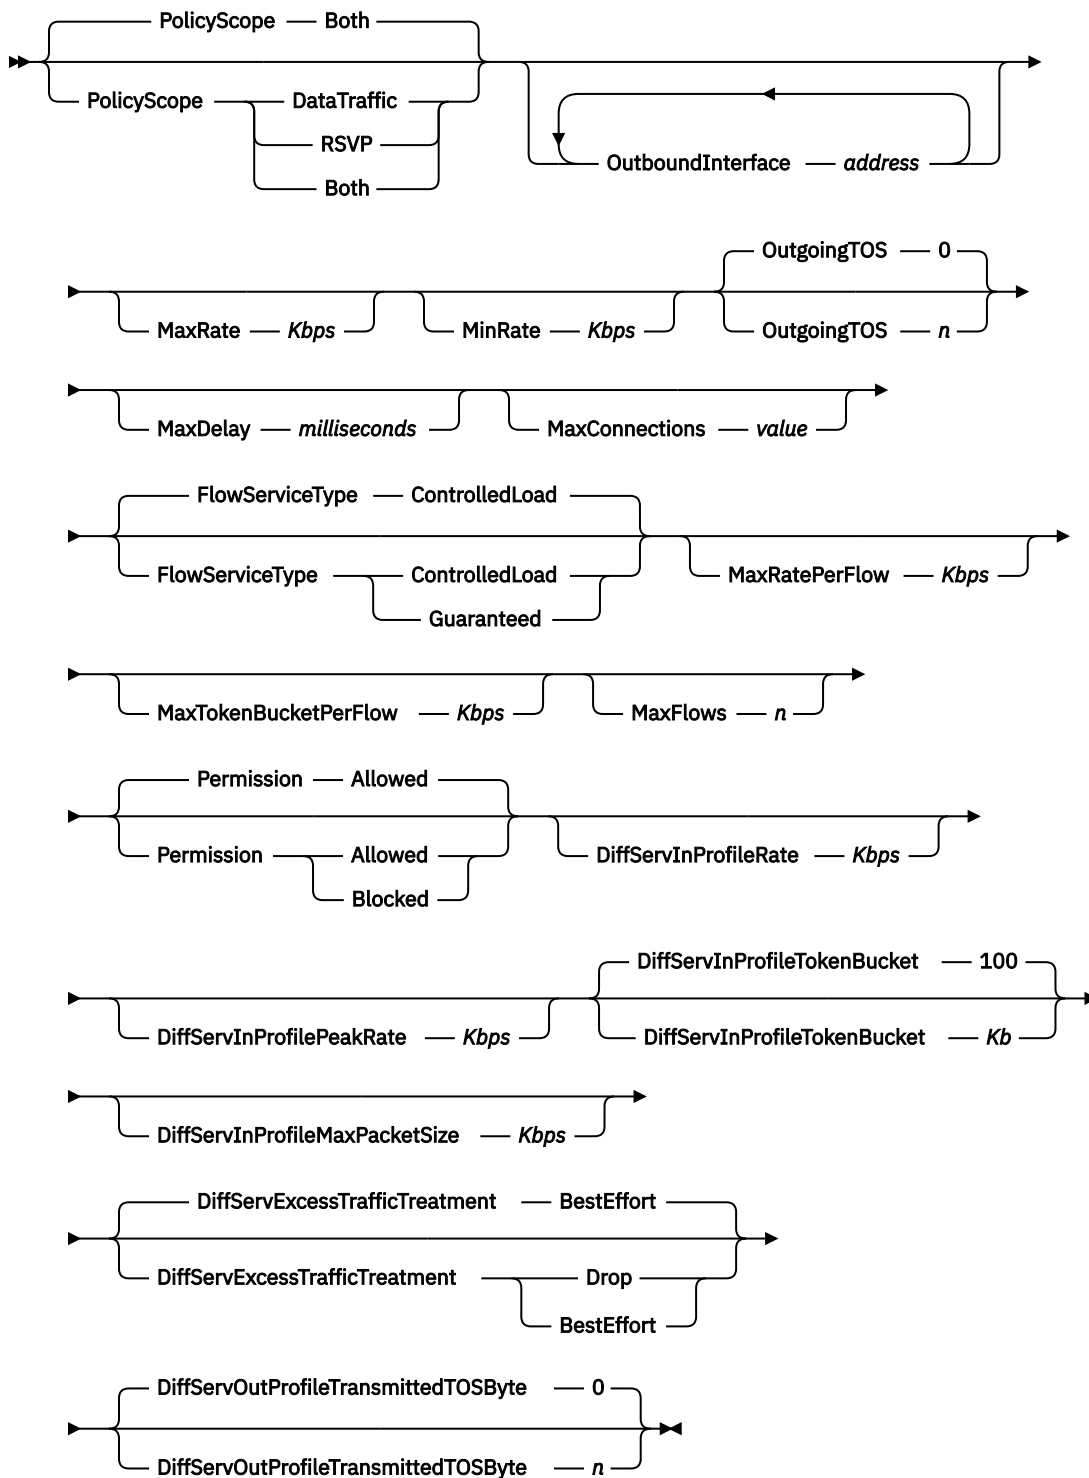

Syntax

► PolicyAction — *name* — Place Braces and Parameters on Separate Lines ◄

Place Braces and Parameters on Separate Lines

PolicyAction Parameters

Parameters

name

A string 1 - 32 characters in length specifying the name of this policy action.

PolicyScope

Indicates the scope of this PolicyAction. The following values are allowed:

- DataTraffic indicates the scope is Differentiated Services.
- RSVP indicates the scope is Integrated Services (for example, RSVP).
- Both indicates the scope is both DataTraffic + RSVP (this is the default).

Certain attributes of the policy action are used only with certain scope values, as follows:

RSVP

FlowServiceType, MaxRatePerFlow, MaxTokenBucketPerFlow, MaxFlows

DataTraffic

All other attributes (Permission applies to all scope values)

When the scope value is specified as Both, both RSVP and DataTraffic attributes can be specified, but the attributes are only applied to the appropriate scope.

OutboundInterface

Specifies an outbound interface used for sysplex distributor distributing stack. Incoming connection requests can be distributed to different target stacks within the sysplex by the sysplex distributor distributing stack based on VIPADIST statements (which define DXCF interfaces) defined for the corresponding distributing stack.

This attribute selects the DXCF interfaces that are available for the incoming connection request that maps to this policy. You can specify IPv4 and IPv6 addresses. You can specify up to 32 instances of this attribute. The value 0 for IPv4 or :: for IPv6 can be specified for the interface, which indicates to the sysplex distributor distributing stack that if it cannot distribute the request to a target stack on one of the other specified interfaces, then the request can be distributed to any of the other eligible target stacks.

For example, suppose 5 target stacks are defined by VIPADIST statements (1.1.1.1 - 5.5.5.5), and 3 interfaces are defined using the OutboundInterface attribute (1.1.1.1, 2.2.2.2, and 0.0.0.0). If an incoming request cannot be distributed to either 1.1.1.1 or 2.2.2.2, then the specification of the 0 interface indicates that the request should be distributed to any of the remaining stacks (3.3.3.3 - 5.5.5.5) that are eligible to service the request. The PolicyScope attribute must specify either DataTraffic or Both to define interfaces using this attribute.

Result: If OutboundInterface specifies only one type of address (IPv4 or IPv6), then inbound connections of the other type is distributed to all available targets. For example, if only IPv6 addresses are specified for OutboundInterface, then incoming connections to IPv4 DVIPAs are not restricted by OutboundInterface; instead, they are distributed to all available IPv4 targets.

Rules:

- If the IP address is IPv6, it cannot be an IPv4-mapped IPv6 address (in hexadecimal or dotted decimal format) or an IPv6 address with the reserved prefix ::/96. If the IPv6 address is one of these two types, an error message is logged.
- IPv6 policy is installed but is not enforceable in a stack that is not IPv6 enabled.

MaxRate

An integer value representing the maximum rate in kilobits per second (Kbps) allowed for traffic in this service class. This attribute is valid only for TCP. If not specified or specified as 0, there is no enforcement of the maximum rate of a connection by the local host. If a number other than 0 is specified, each TCP connection that is mapped to this PolicyAction has its rate limited to this MaxRate. Enforcement of the MaxRate is performed by the TCP/IP stack by adjusting the TCP congestion window based on the connection round-trip time (the rate is obtained by taking the congestion window and dividing it by the round-trip time; note the units, for example, byte versus bit, second versus millisecond). Because the minimum of the congestion window is one TCP segment size, the

minimum of the MaxRate that can be enforced is one TCP segment over the round-trip time. If a TCP connection has a very small round-trip delay and traverses over a very high bandwidth network (for example, Gbit Ethernet LAN), the minimum rate that this TCP connection can send (one segment per round-trip time) can be high. Therefore, users and network administrators need to know their network characteristics when setting this MaxRate; it might not be enforceable if the minimum TCP rate (for example, one segment over round-trip time) already exceeds this specified MaxRate. As noted, TCP segment size can play a role in this TCP minimum rate; for example, for a given round-trip delay, the larger the segment size, the higher the minimum TCP rate. There are different factors that can affect the TCP segment size, for example, the local MTU size definition, the Path MTU discovery flow (this mechanism is used to discover the maximum MTU size that can be sent into the network without resulting in IP fragmentation), the receivers maximum segment size, and so on.

MinRate

An integer value representing the minimum rate or throughput (Kbps) allowed for traffic in this service class. This attribute is valid only for TCP. If not specified or specified as 0, there is no enforcement on the minimum rate of a connection by the local host. If a number other than 0 is specified, the rate for any TCP connection that is mapped to this PolicyAction does not fall below this MinRate, unless the network is really congested and by maintaining the minimum rate the network throughput might collapse. Enforcement of the MinRate is performed by the TCP/IP stack by manipulating the congestion window over the connection round-trip time. Unlike the enforcement of MaxRate, if TCP minimum rate due to the segment size or the round-trip time, or both, is already high, and the specified MinRate is already below this rate, it is not necessary for the TCP/IP stack to enforce the MinRate.

OutgoingTOS

Eight bits, left-aligned, representing the ToS or Traffic Class value of outbound traffic belonging to this service class. The default is 0.

Tip: An outbound packet with a ToS or Traffic Class value that consists of zeros enables prioritizing outbound OSA data using the WorkLoad Manager service class importance level. This function is enabled with the WLMPriorityQ parameter. For more information about Workload Manager provided-priorities, see [prioritizing outbound OSA-Express data using the WorkLoad Manager service class importance level in z/OS Communications Server: IP Configuration Guide](#). When WLMPriorityQ is enabled, specify an OutgoingTOS value other than 0 if you want to prevent the assignment of write priority based on the WorkLoad Manager service class importance level.

MaxDelay

An integer value representing the maximum delay (in milliseconds) allowed for traffic in this service class. This attribute is valid only for TCP. The TCP/IP stack does not enforce this delay.

Result: This parameter is no longer supported and is ignored.

MaxConnections

An integer value representing the maximum number of end-to-end connections at any instant in time. This attribute is valid only with TCP. It places a limit on the number of TCP connections mapped to this PolicyAction that can be active at a time. If there is a request for a new TCP connection that maps to this PolicyAction and this limit is exceeded, the connection request is rejected. The default is that there is no policy limit. The MaxConnections attribute is enforced by the TCP/IP stack. If the connection request is sent by a remote client, a TCP RST segment is returned to notify the client that the connection is refused. The number of rejected connections is maintained and can be retrieved with the `netstat` command using the `-j` option. If the connection request is sent by an application in the local host (for example, using a connect socket call), a return code of permission denied is returned.

Restriction: This attribute only affects new connection requests, not already active connections. For example, if a policy is activated that limits the maximum number of connections to 10, but 15 connections already existed for traffic that maps to the policy rule, then only 10 of the existing connections are mapped to the policy and no new connections are accepted. However, the five other existing connections over the limit remain active and unmapped by the policy.

FlowServiceType

Limits the Type of Service being requested by RSVP applications. Valid values are ControlledLoad (the default) and Guaranteed. Guaranteed service is considered to be *greater than* ControlledLoad service. If ControlledLoad service is specified, and an application requests Guaranteed, the requested service is downgraded to ControlledLoad. To allow RSVP applications to request Guaranteed service, specify Guaranteed for this parameter. All RSVP parameters, FlowServiceType, MaxRatePerFlow, MaxTokenBucketPerFlow, and MaxFlows, are enforced by the RSVP daemon application and not by the TCP/IP stack. The TCP/IP stack, however, maintains traffic statistics of RSVP policies, which can be retrieved with the netstat command with option -j.

MaxRatePerFlow

Specifies the maximum rate in kilobits per second for RSVP flows. RSVP reservations are based on a traffic specification (Tspec) from the sending application. The Tspec consists of the following values:

- r is the token bucket rate in bytes per second.
- b is the token bucket depth in bytes.
- p is the peak rate in bytes per second.
- m is the minimum packet size in bytes.
- M is the maximum packet size (MTU) in bytes.

Use this parameter to limit the r value of the Tspec. If an RSVP sender application requests a Tspec r value larger than this parameter, the request is downgraded to this parameter value.

RSVP receiving applications also specify a resource specification (Rspec) when using Guaranteed service, as part of the reservation request. The Rspec consists of the following values:

- R is the rate in bytes per second.
- S is the slack term in microseconds.

This parameter is also used to limit the R value of the Rspec for reservation requests from RSVP receiver applications using Guaranteed service.

Guideline: This parameter is specified in kilobits per second, while the Tspec and Rspec use bytes per second. To arrive at a compatible specification, multiply the desired Tspec or Rspec value by 8, then divide by 1000. For example, to specify a Tspec r value of 500000 bytes per second, specify a MaxRatePerFlow value of 4000 ($500000 * 8 / 1000 = 4000$).

The default for this parameter is a system defined maximum.

MaxTokenBucketPerFlow

Specifies the maximum token bucket size in kilobits per second for RSVP flows. RSVP reservations are based on a traffic specification (Tspec) from the sending application. The Tspec consists of the following values:

- r is the token bucket rate in bytes per second.
- b is the token bucket depth in bytes.
- p is the peak rate in bytes per second.
- m is the minimum packet size in bytes.
- M is the maximum packet size (MTU) in bytes.

This parameter limits the b value of the Tspec. If an RSVP sender application requests a Tspec b value larger than this parameter, the request is downgraded to this parameter value.

Guideline: This parameter is specified in kilobits, while the Tspec uses bytes. To arrive at a compatible specification, multiply the desired Tspec value by 8, then divide by 1000. For example, to specify a Tspec b value of 75000 bytes, specify a MaxTokenBucketPerFlow value of 600 ($75000 * 8 / 1000 = 600$).

The default for this parameter is a system defined maximum.

MaxFlows

Specifies the maximum number of reserved flows allowed for RSVP applications. The default is no limit on the number of reserved flows.

Permission

Indicates whether packets belonging to this policy rule should be discarded or allowed to proceed. Valid values are Allowed and Blocked. The default is Allowed.

DiffServInProfileRate

Specifies the mean rate at which traffic belonging to the corresponding policy must be policed. It is a Kbps value and must be policed in kilobits per second (Kbps). The default value is 0, meaning no policing mechanism is enforced. The DiffServ parameters are enforced by the TCP/IP stack. Statistics regarding in-profile byte count can be retrieved using the `netstat` command with option `-j`. This in-profile count can be used to calculate the amount of traffic sent out of profile. The in-profile count should be equal to or less than the total transmitted byte count unless the count wraps.

Unlike MaxRate/MinRate, which applies on a per TCP connection basis, these DiffServ parameters apply to aggregated flows (multiple TCP connections can be mapped to a single policy action). Also, it is important to note that when DiffServ parameters are enforced against TCP traffic, the TCP minimum rate determines whether the DiffServ parameters are enforceable, as described in the attribute MaxRate. This is due to an optimization provision where TCP is forced to slow down when it attempts to send beyond the committed bandwidth specified with DiffServ parameters in the policy action with DiffServExcessTrafficTreatment specified as Drop. TCP cannot slow down beyond the TCP minimum rate, even if a violation occurs.

This rate that is used to generate tokens in the token bucket traffic policing mechanism, but it is not necessarily the user/application generated traffic rate.

If this attribute is a nonzero value, the DiffServInProfileTokenBucket value must also be nonzero.

Guideline: This parameter is used by a token bucket mechanism to control the outbound traffic.

DiffServInProfilePeakRate

Specifies the peak rate that traffic belonging to the corresponding policy must be policed. It is a Kbps value and must be policed in kilobits per second (Kbps). The default is 0, which means no policing mechanism is enforced against the peak rate if DiffServInProfileRate is nonzero. When nonzero, it must not be less than that of the DiffServInProfileRate. If this attribute is nonzero, DiffServInProfileRate and DiffServInProfileMaxPacketSize must also be nonzero.

A token bucket mechanism used this parameter to control the outbound traffic.

DiffServInProfileTokenBucket

Specifies the maximum burst size that traffic belonging to the corresponding policy must be policed. It is a kilobits value and must be policed in kilobits (Kb). The default is 100 if DiffServInProfileRate is not 0. The DiffServInProfileTokenBucket attribute is used only when the policy action also uses the DiffServInProfileRate attribute.

A token bucket mechanism used this parameter to control the outbound traffic.

DiffServInProfileMaxPacketSize

Specifies the maximum packet size of traffic belonging to the corresponding policy. Its value is used to police traffic against the peak rate. It is a kilobits value with corresponding policy, in kilobits (Kb). The default is 100 if DiffServInProfilePeakRate is not 0.

Guideline: Due to blocking in z/OS Communications Server, multiple packets tend to be sent back to back. If the maximum packet size is set to the size of one packet, traffic exceeds the peak rate, and those packets are sent as out of profile packets (either with a different ToS or Traffic Class value or dropped) if peak rate enforcement is in effect. To prevent this, the attribute must be set in multiples of the maximum packet size or equal to the token bucket size.

DiffServExcessTrafficTreatment

Specifies what action to take when traffic exceeds its profile. Two values can be specified with this attribute:

- Drop
- BestEffort

The default is BestEffort. These are described directly below.

When the DiffServExcessTrafficTreatment is Drop and the corresponding policy is defined for TCP traffic, z/OS Communications Server optimizes performance by simulating the TCP packet drop and reducing the TCP transmit rate in order to force the outbound traffic to conform to the policy defined bandwidth. This means that the TCP packets that result in excess traffic are transmitted, but the corresponding TCP connections are forced to slow down immediately (by half, which is the TCP behavior under packet loss). This helps avoid retransmissions and prevents further excess traffic. If the policy is defined for UDP, because there is no slowdown mechanism in UDP as in TCP, excess traffic is discarded as specified in the policy definition.

When the DiffServExcessTrafficTreatment is BestEffort, the excess packets are still sent; however, they are sent with the ToS or Traffic Class value specified on DiffServOutProfileTransmittedTOSByte.

DiffServOutProfileTransmittedTOSByte

Specifies the ToS/DS or Traffic Class value to send with the excess traffic (if action is to send excess traffic as best effort instead of dropping).

The normal in profile ToS or Traffic Class value comes from the current OutgoingTOS attribute. This value is specified as a string of eight 1s and 0s. The default is 00000000.

Tip: An outbound packet with a ToS or Traffic Class value that consists of zeros enables prioritizing outbound OSA data using the WorkLoad Manager service class importance level. This function is enabled with the WLMPriorityQ parameter. For more information about Workload Manager provided-priorities, see [prioritizing outbound OSA-Express data using the WorkLoad Manager service class importance level in z/OS Communications Server: IP Configuration Guide](#). When WLMPriorityQ is enabled, specify a DiffServOutProfileTransmittedTOSByte value other than 0 if you want to prevent the assignment of OSA priority based on the WorkLoad Manager service class importance level.

Table 84 on page 1089 provides a mapping of PolicyAction statement parameters to LDAP object classes and attributes.

<i>Table 84. PolicyAction mapping to LDAP</i>		
PolicyAction statement parameter	Object class	LDAP attribute

For an example of the PolicyAction statement, see /usr/lpp/tcpip/samples/pagent.conf.

PolicyRule statement

Use the PolicyRule statement to specify characteristics of IP packets that are used to map to a corresponding policy action. It defines a set of IP datagrams that should receive a particular service.

Restriction: This statement defines a Version 2 policy rule.

Syntax

►► PolicyRule — *name* — Place Braces and Parameters on Separate Lines ◄◄

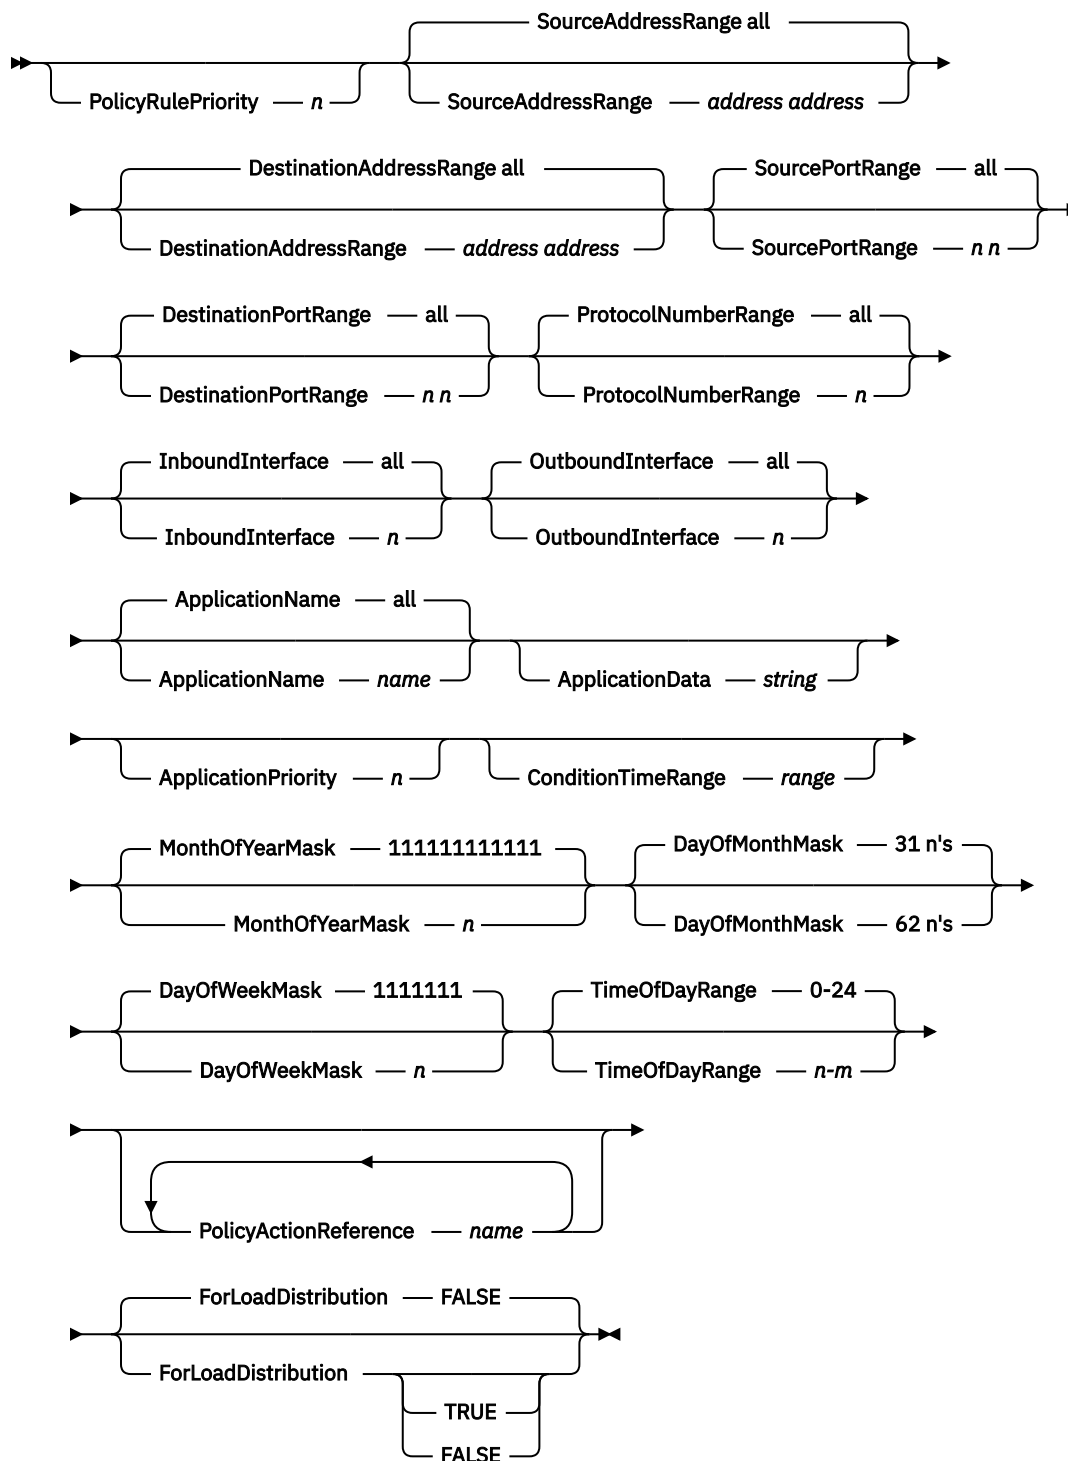

Place Braces and Parameters on Separate Lines

```

►► {
  PolicyRule Parameters
}
◄◄

```

PolicyRule Parameters

Parameters

name

A string 1 - 32 characters in length specifying the name of this policy rule.

PolicyRulePriority

PolicyRulePriority specifies the location of the PolicyRule entry in the PolicyRule list. This is an integer type field. Rules are searched for a match starting at the highest priority, so if multiple rules could possibly be matched for a given set of traffic, the rule with the highest priority gets matched first. If multiple rules have the same priority, then the rule with the greatest number of attributes specified gets matched first. If the match criteria is equal, the rule that gets mapped is unpredictable.

Only one policy is ever mapped, per PolicyScope attribute. The maximum value for this attribute is 2000000000. If this attribute is specified, the computed priority of the rule is the specified value plus 100. If this attribute is not specified, the computed priority of the rule is determined by the number of selection criteria specified, but is always less than 100. The higher the number defined, the higher the assigned priority.

SourceAddressRange

Specifies the source addresses of the sender of the traffic flow. The destination of the data can be the client or the server. For TCP connections, the destination of the connection is the client. For inbound connections or traffic, the source is the remote device. For outbound connections or traffic, the source is this host. Both IPv4 and IPv6 addresses can be specified.

Rules:

- Include a blank or a dash (-) as a delimiter.
- If the IP address is IPv6, it cannot be an IPv4-mapped IPv6 address (in hexadecimal or dotted decimal format) or an IPv6 address with the reserved prefix ::/96. If the IPv6 address is one of these two types, an error message is logged.
- IPv6 policy is installed but is not enforceable in a stack that is not IPv6 enabled.

When the source address range is specified on an LDAP server using the syntax that means *all local addresses*, loopback and loopback-like traffic (for example, otracert from and to a local address), are not mapped due to performance reasons. However, the interface attribute can be specified in addition to the source address to accomplish this mapping.

DestinationAddressRange

Specifies the destination addresses of the receiver of the traffic flow. The destination of the data might be the client or the server. For inbound connections or traffic, the destination of the connection is this host. For outbound connections or traffic, the destination of the connection is the remote device. Both IPv4 and IPv6 addresses can be specified.

Rules:

- Include a blank or a dash (-) as a delimiter.
- If the IP address is IPv6, it cannot be an IPv4-mapped IPv6 address (in hexadecimal or dotted decimal format) or an IPv6 address with the reserved prefix ::/96. If the IPv6 address is one of these two types, an error message is logged.
- IPv6 policy is installed but is not enforceable in a stack that is not IPv6 enabled.

When the destination address range is specified on an LDAP server using the syntax that means *all local addresses*, loopback and loopback-like traffic (for example, otracert from and to a local address), it are not mapped due to performance reasons. However, the interface attribute can be specified in addition to the destination address to accomplish this mapping.

SourcePortRange

The source port range. This field consists of two port numbers, separated by a space, where the first port number is less than or equal to the second port number. The default is 0, which is all inclusive. The source of the data can be the client or the server. For inbound connections or traffic, the source is the remote device. For outbound connections or traffic, the source is this host.

Rule: Include a blank, a colon (:), or a dash (-) as a delimiter.

DestinationPortRange

The destination port range. This field consists of two port numbers, separated by a space, where the first port number is less than or equal to the second port number. The default is 0, which is all inclusive. The destination of the data can be the client or the server. For inbound connections or traffic, the destination is this host. For outbound connections or traffic, the destination is the remote device.

Rule: Include a blank, a colon (:), or a dash (-) as a delimiter.

ProtocolNumberRange

This attribute specifies the protocol range for which this policy rule applies. The format is i1:i2, where i2 >= i1. The maximum value for this attribute is 255. The minimum value is 0, and the default is all protocols. The default and minimum value is 0 and designates all protocols.

Rule: Include a blank, a colon (:), or a dash (-) as a delimiter.

InboundInterface

This attribute specifies the inbound local IP subnet for which this policy rule applies. This can be an IPv4 address or an interface name. The default is all interfaces. If an interface name is specified, it must match a name specified on one of the following statements in the TCP/IP profile:

- LINK statement for an IPv4 interface
- INTERFACE statement for an IPv4 or IPv6 interface

Rules:

- InboundInterface and OutboundInterface attributes should not be specified for the same rule, because that would imply a function that is provided by a router.
- The IPv4 address or interface that is defined must be a physical IP address or a physical device, not a virtual device.

OutboundInterface

This attribute specifies the outbound local IP subnet for which this policy rule applies. This can be an IPv4 address or an interface name. The default is all interfaces. If an interface name is specified, it must match a name specified on one of the following statements in the TCP/IP profile:

- LINK statement for an IPv4 interface
- INTERFACE statement for an IPv4 or IPv6 interface

Rules:

- InboundInterface and OutboundInterface attributes should not be specified for the same rule, because that would imply a function that is provided by a router.
- The IPv4 address or interface that is defined must be a physical IP address or a physical device, not a virtual device.

ApplicationName

ApplicationName is a field of type string (up to eight characters) that specifies the job name of the application. Names longer than eight characters are truncated. A trailing asterisk indicates a wildcard specification. For example, if FTPD* is specified, job names of FTPD and FTPD1 match. The application name maps to the sending application for outbound data, and to the receiving application name for inbound data. The name specified here is not case sensitive, and is translated to uppercase before being compared to application names.

The default is all applications.

ApplicationData

This string field of up to 128 characters specifies the application selector data (for example, a URI for the Internet). Strings longer than 128 characters are truncated. Conceptually, this is a *virtual* URL or URL template that is used for selection; it is not necessarily the entire URL. The string specified here is case sensitive.

This parameter is matched against a token provided by application programs. This token might be implicitly provided by users of the Fast Response Cache Accelerator (FRCA) function, in which case the token is a web URI. It might also be explicitly provided by applications using the sendmsg() function with QoS classification ancillary data. See [z/OS Communications Server: IP Programmer's Guide and Reference](#) for more details on this support.

Tip: The specified character string can be a subset of the application-defined token. Specified URIs should begin with the first character of the path component of the URL.

For example, to select a URL of http://www.ibm.com:80/account/order.html, specify the following:

```
ibm-ApplicationData = /account/order.html
```

Granularity can be determined when defining policy rules based on application defined data. For example, if the installation wants to assign a service level for all URLs under the *account* path, specify:

```
ibm-ApplicationData = /account
```

This specification would match all URLs beginning with /account (for example, /account/order/info.html).

Note:

1. When URIs are specified for Web Server requests, they have an affect on both static and dynamic content (assuming that the corresponding Web Server support is installed).
2. This parameter provides the ability to specify rules that match the application-defined token specified by any applications that are providing QoS application classification data. For more information, see [z/OS Communications Server: IP Sockets Application Programming Interface Guide and Reference](#).

ApplicationPriority *n*

Specifies the QoS service level assigned for each application-specified priority and can have the following values:

0

Any application priority. This specification matches any application-specified priority value.

1

Specifies EXPIDITED priority.

2

Specifies HIGH priority.

3

Specifies MEDIUM priority.

4

Specifies LOW priority.

5

Specifies BESTEFFORT priority.

Restriction: ApplicationPriority is used to select traffic with a matching application-specified priority value. It does not assign a QoS service level to the traffic. That function is provided by the corresponding PolicyAction.

For more information about providing classification data for differentiated services policies from an application, see [z/OS Communications Server: IP Programmer's Guide and Reference](#).

ConditionTimeRange

This field specifies an overall range of calendar dates and times over which a policy rule is valid. It is a string consisting of a start date and time, then a colon (:) followed by an end date and time. The first date indicates the beginning of the range, and the second date indicates the end of the range. Thus, the second date and time must be later than the first. Dates are expressed as substrings of the form *yyyymmddhhmmss*. Seconds are rounded to the nearest minute. Because all dates and times are converted internally to the Posix time format, do not specify dates and times before the start of the Posix epoch, which is January 1, 1970, 00:00:00 UTC.

For example, 20010101080000:20010131120000 is January 1, 2001, 0800 through January 31, 2001, noon.

Note:

1. The internal Posix time format is expressed in terms of seconds since the epoch, which means the time wraps sometime early in the year 2038. Therefore, do not specify dates or times later than this.
2. All dates and times refer to local time.

MonthOfYearMask

This string field specifies which months of the year the policy rule is valid. This attribute is formatted as a string containing 12 0's and 1's, where the 1's identify the months (beginning with January) in which the policy rule is valid. The value 000010010000, for example, indicates that a policy rule is valid only in the months May and August. If this attribute is omitted, then the policy assumes that it is valid for all twelve months.

DayOfMonthMask

This string field specifies which days of the month the policy rule is valid. The day of month mask can be 31 or 62 bits. The second 31 bits specify the days of the month in reverse order. Bit 32 is the last day of the month, bit 33 is the second from last day of month, and so on. This attribute is formatted as a string containing 31 or 62 0's and 1's, where the 1's identify the days of the month in which the policy rule is valid. The value 11100000000000000000000000000000, for example, indicates that a policy rule is valid only on the first three days of each month. For months with less than 31 days, the digits corresponding to the *missing* days are ignored.

The default is every day of the month.

DayOfWeekMask

A mask of seven bits representing the days in a week (Sunday through Saturday) that this policy rule is active. For example, 0111110 represents weekdays. The default is all week.

TimeOfDayRange

A series of time intervals that indicate the time of day, expressed in local time, during which this policy rule is active. Separate intervals with a comma. You can specify hours and optional minutes, separated by a colon. The values 0 and 24 both indicate midnight. Each interval consists of two values separated by a dash. If the second value is smaller than or equal to the first value, then the interval spans midnight. For example, the following statement would result in this policy rule being active from 5:30 PM until 8:30 AM:

```
TimeOfDayRange 0-8:30, 17:30-24
```

You can also configure the same time interval as follows:

```
TimeOfDayRange 17:30-8:30
```

The default is 24 hours.

PolicyActionReference

Indicates the name of a policy action from a policy action statement (for example, interactive) that this policy rule uses.

A maximum of four action references can be specified.

ForLoadDistribution

Specifies whether or not the policy rule is intended for Sysplex Distribution. Valid values are TRUE and FALSE. The default is FALSE. When TRUE is specified, the policy rule is used on sysplex distributor distributing stacks to route connection requests inbound from the network to one or more target stacks.

Table 85 on page 1095 provides mapping of the PolicyRule statement parameters to LDAP object classes and attributes.

Table 85. PolicyRule mapping to LDAP		
PolicyRuleStatement parameter	LDAP object class	LDAP attribute

Also, for more information about policy schema definition files, see [Chapter 18, “Intrusion detection services policy,”](#) on page 1155.

Examples

For an example of the PolicyRule statement, see `/usr/lpp/tcpip/samples/pagent.conf`.

Usage notes

If PolicyRulePriority is specified, the weight of PolicyRule is equal to the specified priority plus 100. Otherwise, the weight is determined by the number of parameters that are specified in the PolicyRule. The parameters that affect this weight are:

- ApplicationName
- ApplicationData
- ApplicationPriority
- SourceAddressRange
- DestinationAddressRange
- SourcePortRange
- DestinationPortRange
- InboundInterface
- OutboundInterface
- Direction *not* equal to BOTH
- ProtocolNumberRange

ServiceCategories statement

Use the ServiceCategories statement to specify the Type of Service that a flow of IP packets (for example, from a TCP connection, or UDP data) should receive end to end as they traverse the network. ServiceCategories can be repeated, with each having a different name so that they can be referenced later.

Restriction: This statement defines a Version 1 policy action.

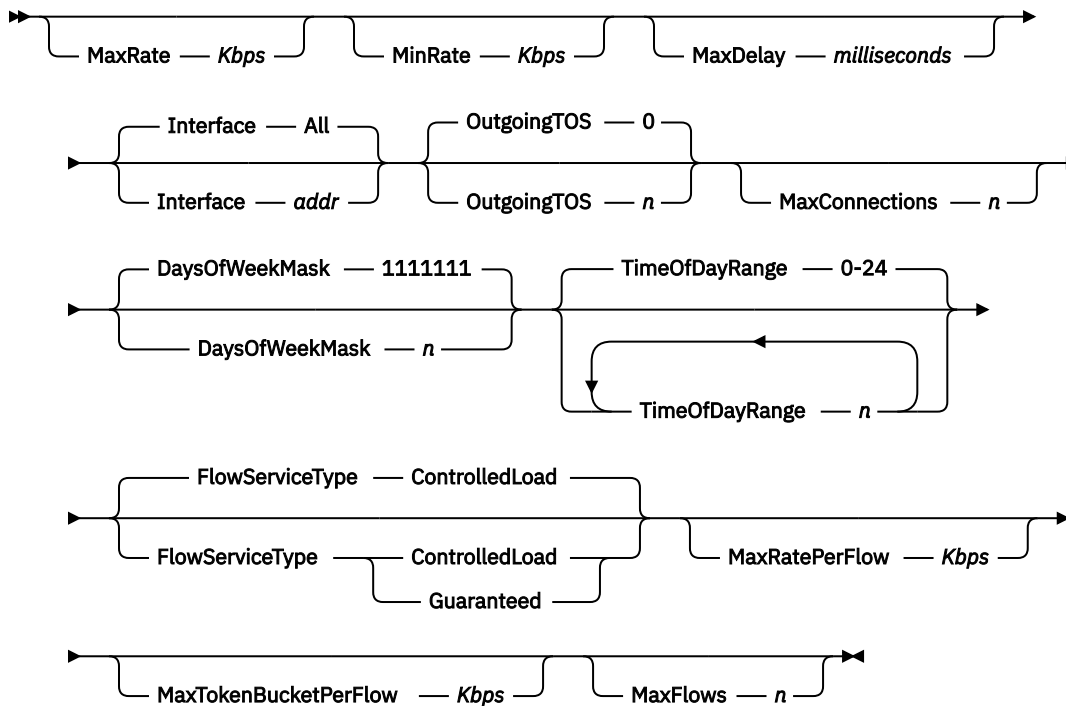

Syntax

►► ServiceCategories — *name* — Place Braces and Parameters on Separate Lines ◄◄

Place Braces and Parameters on Separate Lines

►► {
 ServiceCategories Parameters
 }
◄◄

ServiceCategories Parameters

Parameters

name

A string 1 - 32 characters in length specifying the name of this service category.

MaxRate

An integer value representing the maximum rate in kilobits per second (Kbps) allowed for traffic in this service class. This attribute is valid for only or TCP. If not specified or specified as 0, there is no enforcement of the maximum rate of a connection by the local host. If a number other than 0 is specified, each TCP connection that is mapped to this ServiceCategories has its rate limited to this MaxRate. Enforcement of the MaxRate is performed by the TCP/IP stack by adjusting the TCP congestion window based on the connection round-trip time (the rate is obtained by taking the congestion window and dividing it by the round-trip time; pay attention to the units, for example, byte versus bit, second versus millisecond). Because the minimum of the congestion window is one TCP segment size, the minimum of the MaxRate that can be enforced is one TCP segment over the round-trip time. If a TCP connection has a very small round-trip delay and traverses over a very high bandwidth network (for example, Gbit Ethernet LAN), the minimum rate that this TCP connection can send (one segment per round-trip time) can be high. Therefore, users and network administrators need to know their network characteristics when setting this MaxRate; it might not be enforceable if the minimum TCP rate (for example, one segment over round-trip time) already exceeds this specified MaxRate. As noted, TCP segment size can play a role in this TCP minimum rate; for example, for a given round-trip delay, the larger the segment size the higher the minimum TCP rate. There are different factors that can affect the TCP segment size, such as the local MTU size definition, the Path MTU discovery flow (for example, this mechanism is used to discover the maximum MTU size that can be sent into the network without resulting in IP fragmentation), the receivers maximum segment size, and so on.

MinRate

An integer value representing the minimum rate or throughput (Kbps) allowed for traffic in this service class. This attribute is valid only for TCP. If not specified or specified as 0, there is no enforcement on the minimum rate of a connection by the local host. If a number other than 0 is specified, the rate for any TCP connection that is mapped to this ServiceCategories does not fall below this MinRate, unless the network is really congested and by maintaining the minimum rate the network throughput might collapse. Enforcement of the MinRate is performed by the TCP/IP stack by manipulating the congestion window over the connection round-trip time. Unlike the enforcement of MaxRate, if TCP

minimum rate due to the segment size or the round-trip time, or both, is already high, and the specified MinRate is already below this rate, it is not necessary for the TCP/IP stack to enforce the MinRate.

MaxDelay

An integer value representing the maximum delay (in milliseconds) allowed for traffic in this service class. This attribute is valid only for TCP. The TCP/IP stack does not enforce this delay.

Result: This parameter is no longer supported and is ignored.

Interface

The local IP subnet (for example, HOME statements) for which this service category applies. The default is all interfaces.

OutgoingTOS

Eight bits, left-aligned, representing the ToS value of outbound traffic belonging to this service class. The default is 0.

MaxConnections

An integer value representing the maximum number of end to end connections at any instant in time. This attribute is valid only with TCP. It places a limit on the number of TCP connections mapped to this ServiceCategories that can be active at a time. If there is a request for a new TCP connection that maps to this ServiceCategories and this limit is exceeded, the connection request is rejected. The default is that there is no policy limit. The MaxConnections attribute is enforced by the TCP/IP stack. If the connection request comes from a remote client, a TCP RST segment is returned to notify the client that the connection is refused. The number of rejected connections is kept and can be retrieved by the netstat command with -j option. If the connection request comes from an application in the local host (for example, using a connect socket call), a return code of permission denied is returned.

DaysOfWeekMask

A mask of seven bits representing the days in a week (Sunday through Saturday) that this service policy is active. For example, 0111110 represents weekdays. The default is all week.

TimeOfDayRange

A series of time intervals that indicate the time, expressed in local time, during which this service policy is active. Separate intervals with a comma. You can specify hours and optional minutes, separated by a colon. The values 0 and 24 both indicate midnight. Each interval consists of two values separated by a dash. If the second value is smaller than or equal to the first value, then the interval spans midnight. For example, the following statement results in this service policy being active from 5:30 PM until 8:30 AM:

```
TimeOfDayRange 0-8:30, 17:30-24
```

You can also configure the same time interval as follows:

```
TimeOfDayRange 17:30-8:30
```

The default is 24 hours.

FlowServiceType

Limits the Type of Service being requested by RSVP applications. Valid values are ControlledLoad (the default) and Guaranteed. Guaranteed service is considered to be *greater than* ControlledLoad service. If ControlledLoad service is specified, and an application requests Guaranteed, the requested service is downgraded to ControlledLoad. To allow RSVP applications to request Guaranteed service, specify Guaranteed for this parameter. All RSVP parameters, FlowServiceType, MaxRatePerFlow, MaxTokenBucketPerFlow, and MaxFlows are enforced by the RSVP daemon application and not by the TCP/IP stack. The TCP/IP stack, however, keeps traffic statistics of RSVP policies, which can be retrieved by using netstat command with the option -j.

MaxRatePerFlow

Specifies the maximum rate in kilobits per second for RSVP flows. RSVP reservations are based on a traffic specification (Tspec) from the sending application. The Tspec consists of the following values:

- *r* is the token bucket rate in bytes per second.

- b is the token bucket depth in bytes.
- p is the peak rate in bytes per second.
- m is the minimum packet size in bytes.
- M is the maximum packet size (MTU) in bytes.

Use this parameter to limit the r value of the Tspec. If an RSVP sender application requests a Tspec r value larger than this parameter, the request is downgraded to this parameter value.

RSVP receiving applications also specify a resource specification (Rspec) when using Guaranteed service, as part of the reservation request. The Rspec consists of the following values:

- R is the rate in bytes per second.
- S is the slack term in microseconds.

This parameter is also used to limit the R value of the Rspec for reservation requests from RSVP receiver applications using Guaranteed service.

This parameter is specified in kilobits per second, while the Tspec and Rspec use bytes per second. To arrive at a compatible specification, multiply the desired Tspec or Rspec value by 8, then divide by 1 000. For example, to specify a Tspec r value of 500 000 bytes per second, specify a MaxRatePerFlow value of 4 000 ($500\,000 * 8 / 1\,000 = 4\,000$).

The default for this parameter is a system defined maximum.

MaxTokenBucketPerFlow

Specifies the maximum token bucket size in kilobits per second for RSVP flows. RSVP reservations are based on a traffic specification (Tspec) from the sending application. The Tspec consists of the following values:

- r is the token bucket rate in bytes per second.
- b is the token bucket depth in bytes.
- p is the peak rate in bytes per second.
- m is the minimum packet size in bytes.
- M is the maximum packet size (MTU) in bytes.

This parameter is used to limit the b value of the Tspec. If an RSVP sender application requests a Tspec b value larger than this parameter, the request is downgraded to this parameter value.

This parameter is specified in kilobits, while the Tspec uses bytes. To arrive at a compatible specification, multiply the desired Tspec value by 8, then divide by 1 000. For example, to specify a Tspec b value of 75 000 bytes, specify a MaxTokenBucketPerFlow value of 600 ($75\,000 * 8 / 1000 = 600$).

The default for this parameter is a system defined maximum.

MaxFlows

Specifies the maximum number of reserved flows allowed for RSVP applications. The default is no limit on the number of reserved flows.

Examples

Following is an example of the ServiceCategories Version 1 Action statement.

```

ServiceCategories V1Action
{
PolicyScope Both
MaxRate 10000
MinRate 2000
MaxTokenBucket 5000
Interface 9.67.116.98
OutgoingTOS 11100000
MaxDelay 50
MaxConnections 100
DaysOfWeekMask 1111111
TimeOfDayRange 08:00-13:45,13:50-24:00
FlowServiceType Guaranteed
MaxRatePerFlow 440# 55000 bytes/second
MaxTokenBucketPerFlow 48 # 6000 bytes
MaxFlows 10
}

```

Figure 26. Example of the ServiceCategories Version 1 Action statement

ServicePolicyRules statement

Use the ServicePolicyRules statement to specify characteristics of IP packets that are used to map to a corresponding service category; it defines a set of IP datagrams that should receive a particular service.

Restriction: This statement defines a Version 1 Service Policy Rule.

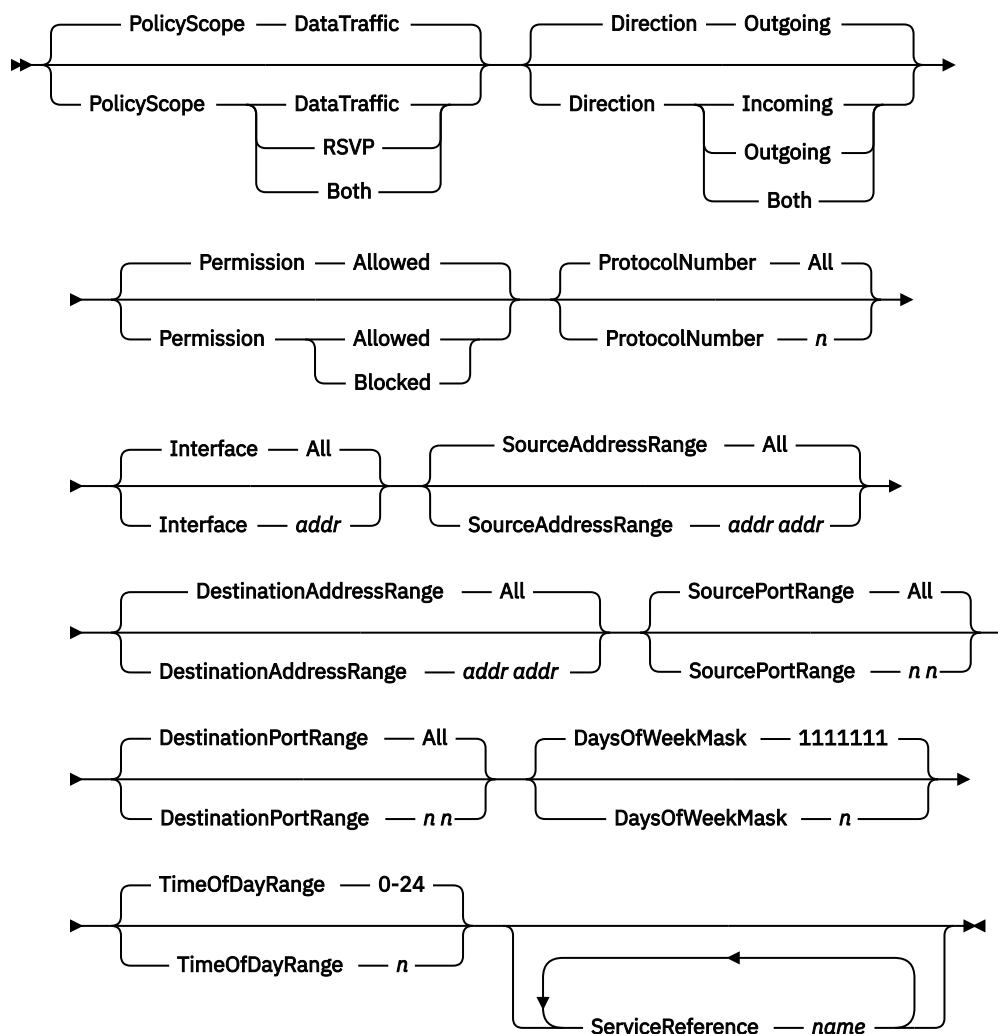

Syntax

►► ServicePolicyRules — *name* — Put Braces and Parameters on Separate Lines ◀◀

Put Braces and Parameters on Separate Lines

ServicePolicyRules Parameters

Parameters

name

A string 1 - 32 characters in length specifying the name of this policy rule.

PolicyScope

Indicates to what traffic this policy rule applies. Valid values are *DataTraffic*, *RSVP*, and *Both*. The default is *DataTraffic*. When RSVP (Resource reSerVation Protocol, a network protocol running on top of IP) is specified, this policy only applies to data that are specifically reserved by using RSVP. When *DataTraffic* is specified, the policy applies to all other non-RSVP data.

Direction

Indicates the direction of traffic for which this policy rule applies. Valid values are *Incoming*, *Outgoing*, and *Both*. The default is *Outgoing*.

Restriction: Policies are applied to TCP on a connection basis, whereas they are applied to UDP/RAW on a per-packet basis. Therefore, the Direction attribute is also mapped accordingly. More specifically, if a policy is defined for TCP, the Direction attribute applies to the direction of the connection (inbound if the local 390 host is to receive the connection request, such as incoming TCP SYN segments). If a policy is defined for UDP/RAW, Direction applies to individual packets.

Permission

Indicates whether packets belonging to this policy rule should be discarded or allowed to proceed. Valid values are *Allowed* and *Blocked*. The default is *Allowed*.

ProtocolNumber

This is a 1-byte field in the IP header to identify the protocol running on top of IP. Common protocols are UDP and TCP. For UDP, TCP, and RAW, this field can be specified with these names. For others, a number has to be specified (for example, 1 for ping). The default is all protocols.

Interface

The local IP subnet for which this policy rule applies. The default is all interfaces.

SourceAddressRange

The local IP address range. This field consists of two addresses, separated by a space, where the first address is less than or equal to the second address. The default is 0, which is all inclusive.

SourceAddressRange is the address range of addresses that are local to the 390 host (for example, defined by way of HOME statements in the TCP/IP configuration).

Rules:

- Include a blank or a dash (-) as a delimiter.
- If the IP address is IPv6, it cannot be an IPv4-mapped IPv6 address (in hexadecimal or dotted decimal format) or an IPv6 address with the reserved prefix ::/96. If the IPv6 address is one of these two types, an error message is logged.

DestinationAddressRange

The remote IP address range. This field consists of two addresses, separated by a space, where the first address is less than or equal to the second address. The default is 0, which is all inclusive.

DestinationAddressRange is the address range of the remote hosts that are communicating with the local 390 host.

Rules:

- Include a blank or a dash (-) as a delimiter.
- If the IP address is IPv6, it cannot be an IPv4-mapped IPv6 address (in hexadecimal or dotted decimal format) or an IPv6 address with the reserved prefix ::/96. If the IPv6 address is one of these two types, an error message is logged.

SourcePortRange

The local port range. This field consists of two port numbers, separated by a space, where the first port number is less than or equal to the second port number. The default is 0, which is all inclusive.

SourcePortRange contains the port range of the remote hosts that are communicating with the local 390 host.

Rule: Include a blank, a colon (:), or a dash (-) as a delimiter.

DestinationPortRange

The remote port range. This field consists of two port numbers, separated by a space, where the first port number is less than or equal to the second port number. The default is 0, which is all inclusive.

DestinationPortRange contains the address range of the remote hosts that are communicating with the local 390 host.

Rule: Include a blank, a colon (:), or a dash (-) as a delimiter.

DaysOfWeekMask

A mask of seven bits representing the days in a week (Sunday through Saturday) that this policy rule is active. For example, 0111110 represents weekdays. The default is all week.

TimeOfDayRange

A series of time intervals that indicate the time, expressed in local time, during which this policy rule is active. Separate intervals with a comma. You can specify hours and optional minutes, separated by a colon. The values 0 and 24 both indicate midnight. Each interval consists of two values separated by a dash. If the second value is smaller than or equal to the first value, then the interval spans midnight. For example, the following statement results in this policy being active from 5:30 PM until 8:30 AM:

```
TimeOfDayRange 0-8:30, 17:30-24
```

You can also configure the same time interval as follows:

```
TimeOfDayRange 17:30-8:30
```

The default is 24 hours.

ServiceReference

Indicates the name of a service category from a service category statement (for example, interactive) that this policy rule uses. One or more service category names can be specified to associate this policy rule with different interfaces or different service policies depending, for example, on the time when each of those service policies are active.

Examples

Following is an example of the ServicePolicyRules Version 1 statement.

```
ServicePolicyRules V1Rule
{
  PolicyScope Both
  Direction Both
  Permission Allowed
  ProtocolNumber TCP
  Interface 9.67.116.98
  SourceAddressRange 9.67.100.7.9.67.100.11
  DestinationPortRange 100-5000
  DaysOfWeekMask 1111111
  TimeOfDayRange 08:00-23:00
  ServiceReference V1Action
}
```

Figure 27. Example of the ServicePolicyRules Version 1 statement

Usage notes

The weight of ServicePolicyRules is determined by the number of parameters that are specified in the ServicePolicyRules. The parameters that affect this weight are:

- SourceAddressRange
- DestinationAddressRange
- SourcePortRange
- DestinationPortRange
- Interface
- ProtocolNumber
- Direction *not* equal to BOTH
- PolicyScope *not* equal to BOTH

zERT policy-based enforcement policy statements

This topic contains information about the following zERT policy-based enforcement (ZERT) policy statements:

- [“ConnectionDescriptor statement” on page 1105](#)
- [“ConnectionDescriptorGroup statement” on page 1106](#)
- [“ZERTAction statement” on page 1107](#)
- [“ZERTKeyExchange statement” on page 1110](#)
- [“ZERTMessageAuthentication statement” on page 1112](#)
- [“ZERTRule statement” on page 1114](#)
- [“ZERTSSHProtocol statement” on page 1118](#)
- [“ZERTSymmetricEncryption statement” on page 1119](#)

- “ZERTTLSProtocol statement” on page 1121

For an example of ZERT policy definitions see the pagent_ZERT.conf file in the /usr/lpp/tcpip/samples/ directory.

ConnectionDescriptor statement

Use the ConnectionDescriptor statement to describe a connection in terms of one or more of the following characteristics: IP protocol, local and remote port values, job name and the direction from which the connection was initiated. A connection must match each of the ConnectionDescriptor parameters for this rule to match and the action to be performed.

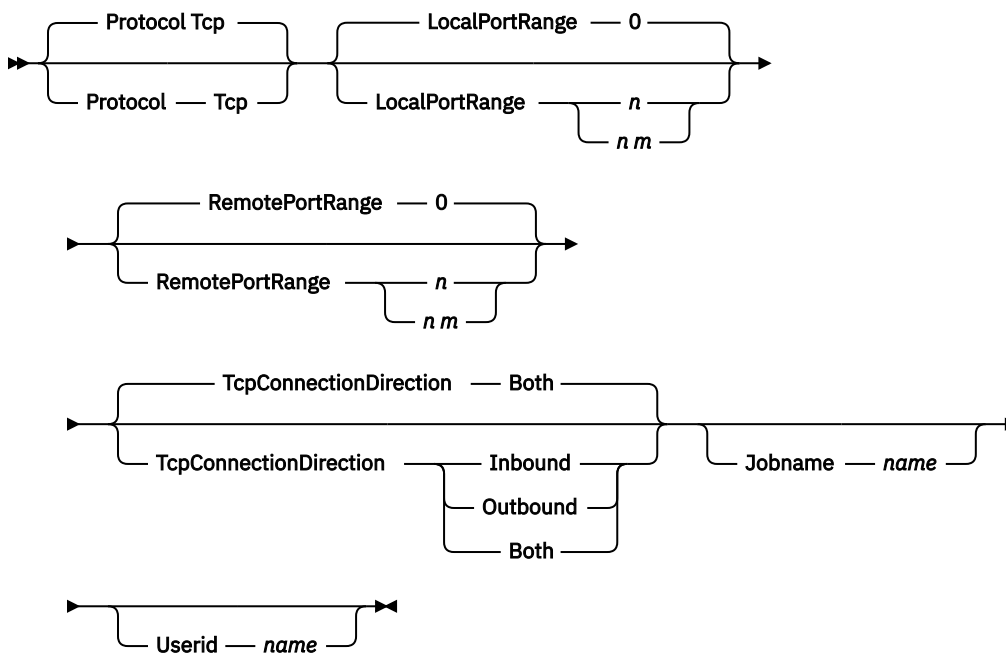

Syntax

Place Braces and Parameters on Separate Lines

ConnectionDescriptor Parameters

Parameters

name

A string 1 - 32 characters in length specifying the name of this ConnectionDescriptor statement.

Rule: If this ConnectionDescriptor statement is not specified inline within another statement, a name value must be provided.

If a name is not specified for an inline ConnectionDescriptor statement, a nonpersistent system name is created.

Protocol

The transport protocol of the connection that must match for the rule's action to be performed.

TCP

Indicates TCP protocol. This is the default.

LocalPortRange

Local port or port range. Valid values for *n* are in the range 0 - 65535. If 0 is specified for *n* then the rule applies to any local port. If *n* is specified as the beginning value for a range, then 0 is not a valid value.

If an *m* value is specified, it must be greater than or equal to *n* and less than 65536.

Rule: Include a blank, a colon (:), or a dash (-) as a delimiter.

RemotePortRange

Remote port or port range. Valid values for *n* are in the range 0 - 65535. If 0 is specified for *n*, then the rule applies to any remote port. If *n* is specified as the beginning value for a range, then 0 is not a valid value.

If an *m* value is specified, then it must be greater than or equal to *n* and less than 65536.

Rule: Include a blank, a colon (:), or a dash (-) as a delimiter.

Jobname

The name value specifies the job name of the application. The name value can be up to 8 characters in length. A trailing asterisk indicates a wildcard specification. The specified name is not case-sensitive, and is translated to uppercase before being compared.

Userid

The name value specifies the z/OS user ID that opened the local socket. The name value must be 1 to 8 characters in length. It cannot include blanks or the "#" characters. A trailing asterisk indicates a wildcard specification. The specified user ID is not case sensitive.

TcpConnectionDirection

Specifies the direction in which the TCP connection is initiated.

Inbound

A TCP connection request has arrived inbound to the local host.

Outbound

A TCP connection request is being initiated outbound from the local host.

Both

Inbound and Outbound TCP connection requests match this rule.

ConnectionDescriptorGroup statement

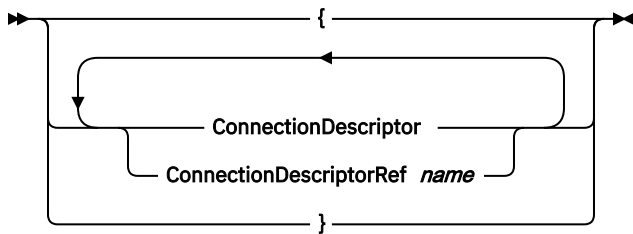

Use the ConnectionDescriptorGroup statement to define a connection descriptor group. A ConnectionDescriptorGroup statement identifies a set of ConnectionDescriptor statements that make up the connection descriptor group.

Restriction: The ConnectionDescriptorGroup statement is available for use only with ZERT policies.

Syntax

► ConnectionDescriptorGroup — — *name* — Place Braces and Parameters on Separate Lines ◄

Place Braces and Parameters on Separate Lines

Parameters

name

A string 1 - 32 characters in length specifying the name of this `ConnectionDescriptorGroup` statement.

ConnectionDescriptor

An inline specification of a `ConnectionDescriptor` statement to be included in this group.

ConnectionDescriptorRef

The name of a globally defined `ConnectionDescriptor` statement to be included in the group.

ZERTAction statement

Use the `ZERTAction` statement to define the actions to be taken for a connection that matches the conditions in a `ZERTRule`. The actions include writing a message to syslogd, writing a console message to the TCP/IP job log, writing a SMF audit record, and resetting a TCP connection. By default, none of these actions are taken and the connection is silently allowed.

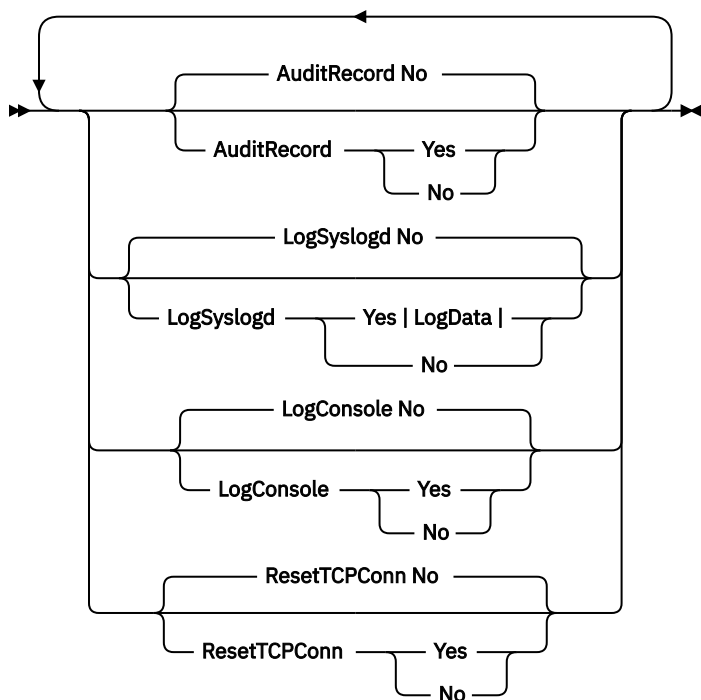

Syntax

➡ ZERTAction — *name* — Put Braces and Parameters on Separate Lines ➡

Place Braces and Parameters on Separate Lines

ZERTAction Parameters

LogData

Parameters

name

A string 1 - 32 characters in length specifying the name of this ZERTAction statement.

AuditRecord

Yes

Write SMF 119 subtype 11 record with event type 7 (zERT enforcement) to SMF and/or to NMI SYSTCPER service.

Restrictions:

- SMFCONFIG TYPE119 ZERTDETAILBYPOLICY must be configured in the TCP/IP profile for SMF records to be generated.
- NETMONITOR ZERTSERVICEBYPOLICY must be configured in the TCP/IP profile for the records to be written to the SYSTCPER NMI service.

No

Do not write SMF 119 subtype 11 record with event type 7.

LogSyslogd

Yes

Log ZERT message about the connection matching the associated ZERTRule to the syslog daemon. If ResetTCPConn is also specified for the action, message "EZZ8584I Connection reset by ZERT Policy Enforcement" is written. Otherwise, message "EZZ8583I Connection logged by ZERT Policy Enforcement" is written. The messages are logged to syslogd using syslogd facility LOCAL5. The syslogd priority is determined by the LogLevel parameter.

Restrictions:

- The syslog daemon must be started. See [Chapter 15, “Syslog daemon,”](#) on page 795 for more information.
- TRMD must be started for the affected TCP/IP stack. See [“Starting the traffic regulation manager daemon \(TRMD\) from the z/OS shell”](#) on page 1145 or [“Starting the traffic regulation manager daemon \(TRMD\) as a started task”](#) on page 1146 for more information.

Tip: To avoid flooding syslogd, zERT policy-based enforcement limits the number of messages that are written to syslogd during a 5-minute interval. For more information on syslogd message suppression, see [zERT enforcement syslogd message suppression in z/OS Communications Server: IP Configuration Guide](#). If a complete record of connections matching this ZERT rule is needed, AuditRecord action should be used.

No

Do not log connection information to syslog daemon.

LogLevel

Indicates the syslogd priority for logging ZERT messages to the syslog daemon.

Valid values are in the range 0 – 7 and map to syslog daemon priority levels:

0

Emerg/Panic

1

Alert

2

Crit

3

Error

4

Warning. This is the default.

5

Notice

6

Info

7

Debug

LogConsole

Yes

Log ZERT messages about the connection matching the associated ZERTRule to the TCP/IP job log. If ResetTCPConn is also specified for the action, message "EZZ8562I CONN RESET BY ZERT POLICY" is written. Otherwise, message "EZZ8551I CONN LOGGED BY ZERT POLICY" is written.

No

Do not log ZERT messages to the console.

Tips:

- To avoid flooding the TCP/IP joblog, zERT policy-based enforcement limits the number of messages that are written to the joblog during a 5-minute interval. For more information on console message suppression, see [zERT enforcement console message suppression in z/OS Communications Server: IP Configuration Guide](#). If a complete record of connections matching this ZERT rule is needed, AuditRecord action should be used.
- To prevent the TCP/IP job log from growing very large and filling up the spool space, ensure that the TCP/IP job log is being spun-off on a regular basis. See [Writing your own master scheduler JCL in z/OS MVS Initialization and Tuning Reference](#), [Determining the source JCL for the started task in z/OS MVS JCL Reference](#) and [JESLOG parameter in z/OS MVS JCL Reference](#) for more information.

ResetTCPConn

Yes

Reset the TCP connection matching the associated ZERTRule.

No

Do not reset the TCP connection.

Tip:

Consider enabling logging (LogConsole or LogSyslogd) for the action to provide awareness that TCP connections are being reset due to a ZERTRule.

ZERTKeyExchange statement

Use the ZERTKeyExchange statement to specify one or more key exchange algorithms for TLS and SSH connections. A connection must be protected using one of the specified key exchange algorithms for this rule to match and the action to be performed.

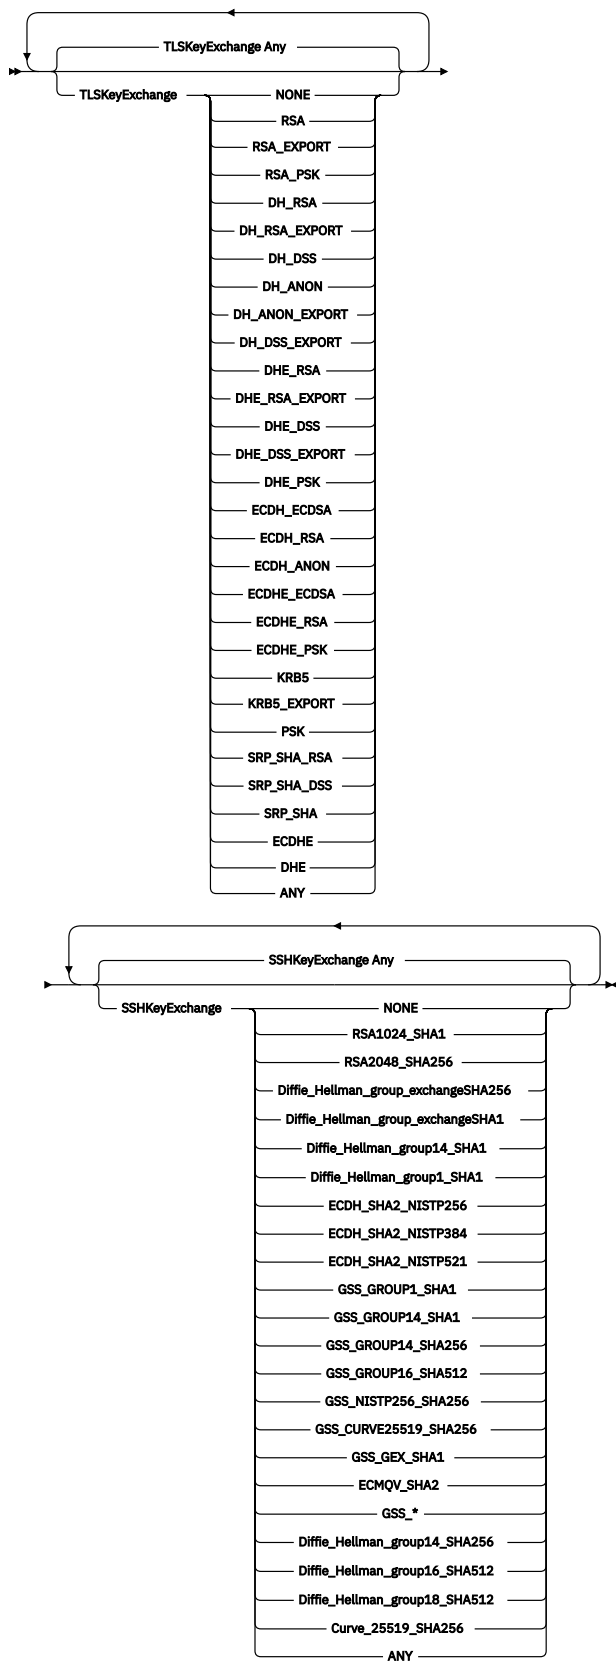

Syntax

Place Braces and Parameters on Separate Lines

ZERTKeyExchange Parameters

Parameters

name

A string 1 - 32 characters in length specifying the name of this ZERTKeyExchange statement.

Rule: If this ZERTKeyExchange statement is not specified inline within another statement, a name value must be provided. If a name is not specified for an inline ZERTKeyExchange statement, a nonpersistent system name is created.

TLSKeyExchange

Specify a TLS key exchange. The default is Any.

SSHKeyExchange

Specify a SSH key exchange. The default is Any.

Restrictions:

- This statement can be referenced by a ZERTRule with SecurityProtocol TLS or SSH.
- If TLSKeyExchange Any is configured for the ZERTKeyExchange statement, the statement cannot contain another TLSKeyExchange parameter for a specific TLS key exchange algorithm or None.
- If SSHKeyExchange Any is configured for the ZERTKeyExchange statement, the statement cannot contain another SSHKeyExchange parameter for a specific SSH key exchange algorithm or None.

ZERTMessageAuthentication statement

Use the ZERTMessageAuthentication statement to specify one or more message authentication algorithms. A connection must be protected using one of the specified message authentication algorithms for this rule to match and the action to be performed.

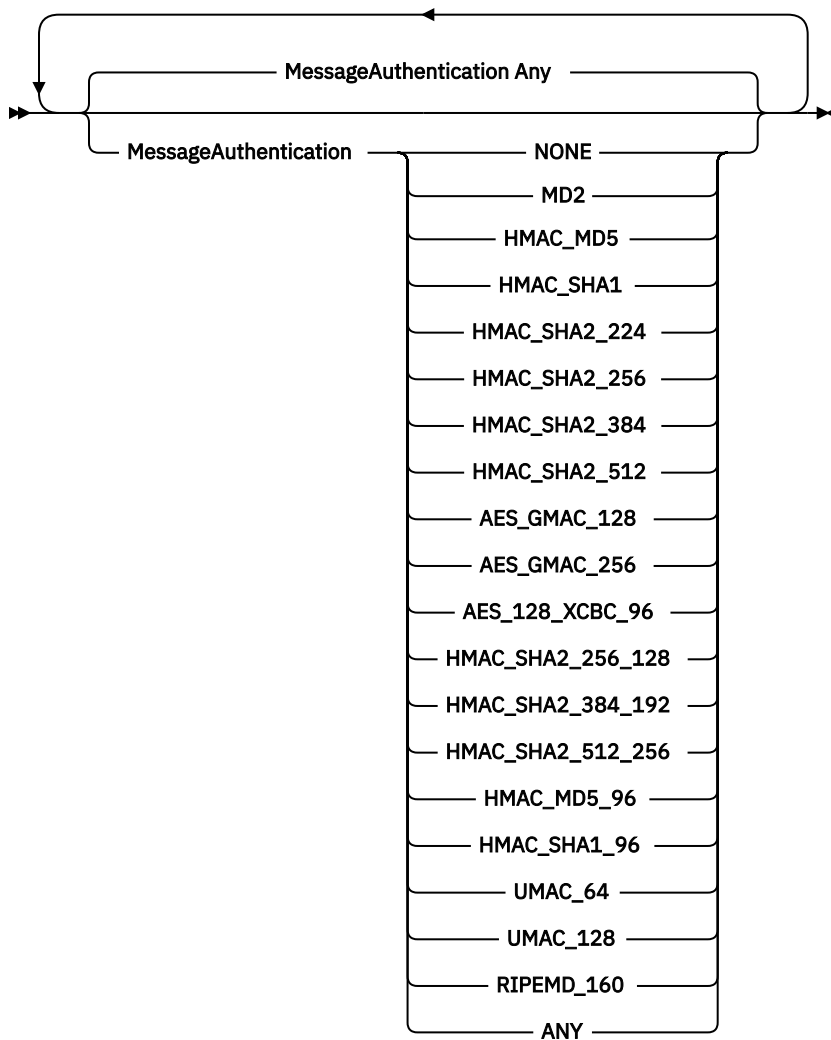

Syntax

Place Braces and Parameters on Separate Lines

ZERTMessageAuthentication Parameters

Parameters

name

A string 1 - 32 characters in length specifying the name of this ZERTMessageAuthentication statement.

Rule: If this ZERTMessageAuthentication statement is not specified inline within another statement, a name value must be provided. If a name is not specified for an inline ZERTMessageAuthentication statement, a nonpersistent system name is created.

MessageAuthentication

Specify a message authentication algorithm. The default is Any.

Tips: For a ZERTRule with SecurityProtocol IPsec:

- The list of message authentication algorithms describes phase 2 tunnel protection.
- AES-GCM is an authenticated encryption algorithm. The associated MessageAuthentication value would be NONE.

Restrictions:

- This statement can be referenced by a ZERTRule with SecurityProtocol TLS, SSH, or IPsec.
- If MessageAuthentication Any is configured for the ZERTMessageAuthentication statement, the statement cannot contain another MessageAuthentication parameter for a specific algorithm or None.

ZERTRule statement

Use the ZERTRule statement to enable zERT policy-based enforcement based on the condition parameters associated with the ZERTRule statement. The ZERTRule statement references a corresponding ZERTAction statement that indicates what actions to take when the rule is matched.

Each ZERTRule is associated with a specific security protocol and is enforced when the TCP/IP stack determines that a TCP connection is protected using that security protocol and matches the other conditions for the rule.

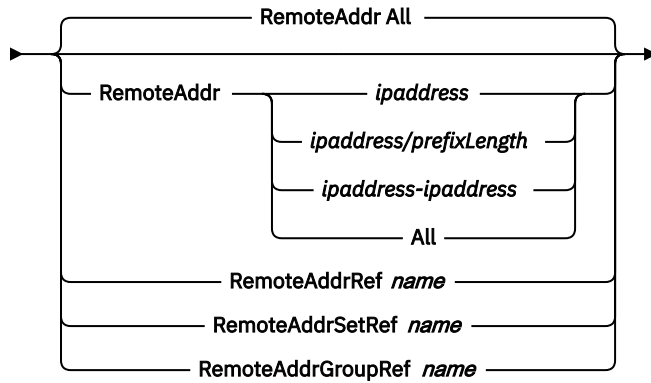

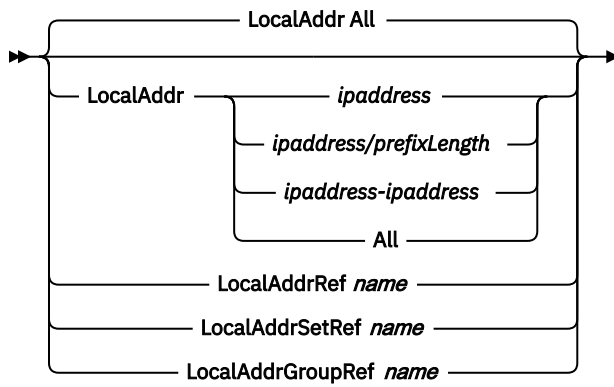

Syntax

➤ ZERTRule — *name* — Put Braces and Parameters on Separate Lines ➤

Place Braces and Parameters on Separate Lines

ZERTRule Parameters

➤ ZERTActionRef — *name* ➤

TLSVersions

SSHVersions

Parameters

name

A string 1 - 32 characters in length specifying the name of this ZERTRule statement.

LocalAddr

A local IP address the application is using for the connection that must match for this rule's action to be performed. The application can be explicitly bound to the IP address, or it can be chosen by the TCP/IP stack.

All

Any local IP address matches this rule.

ipaddress

A single IP address.

ipaddress/prefixLength

The number of unmasked leading bits in the ipaddress value. The prefixLength value can be in the range 0 - 32 for IPv4 addresses and 0 - 128 for IPv6 addresses. An IP address matches this condition if its unmasked bits are identical to the unmasked bits defined.

ipaddress-ipaddress

A range of IP addresses.

Tip: To create a rule that matches only on local IPv4 addresses, code 0.0.0.0/0. To create a rule that matches only on local IPv6 addresses, code ::/0.

LocalAddrRef

The name of a globally defined IpAddr statement to be used for the local IP address specification.

LocalAddrSetRef

The name of a globally defined IpAddrSet statement to be used for the local IP address prefix or range specification.

LocalAddrGroupRef

The name of a globally defined IpAddrGroup statement to be used for the local IP address specification.

RemoteAddr

A remote IP address specification that must match for this rule's action to be performed.

All

Any remote IP address matches this rule.

ipaddress

A single IP address.

ipaddress/prefixLength

The number of unmasked leading bits in the ipaddress value. The prefixLength value can be in the ranges of 0 - 32 for IPv4 addresses and 0 - 128 for IPv6 addresses. An IP packet matches this condition if its unmasked bits are identical to the unmasked bits defined.

ipaddress-ipaddress

A range of IP addresses.

Tip: To create a rule that matches only on remote IPv4 addresses, code 0.0.0.0/0. To create a rule that matches only on remote IPv6 addresses, code ::/0.

RemoteAddrRef

The name of a globally defined IpAddr statement to be used for the remote IP address specification.

RemoteAddrSetRef

The name of a globally defined IpAddrSet statement to be used for the remote IP address prefix or range specification.

RemoteAddrGroupRef

The name of a globally defined IpAddrGroup statement to be used for the remote IP address specification.

ConnectionDescriptor

An inline specification of a ConnectionDescriptor statement.

ConnectionDescriptorRef

The name of a globally defined ConnectionDescriptor statement.

ConnectionDescriptorGroupRef

The name of a globally defined ConnectionDescriptorGroup statement.

Priority

This is an integer value in the range 1 - 2000000000 representing the priority associated with the rule.

Restriction: Rules are searched for a match starting at the highest priority, so if multiple rules could possibly be matched for a connection, the rule with the highest priority gets matched first. If multiple rules of the same priority match, the rule mapped is difficult to predict. If this attribute is not specified, the default priority is 1.

Guideline: When setting the priority for multiple rules, do not set the priority as a sequential value, for example 2, 3, 4, and 5. Instead, set the priority to provide space to change the priority or to insert additional rules, such that the rule would be preferred before another rule, without duplicating a priority. For example, the priorities could be configured as 20, 30, 40, and 50.

SecurityProtocol

The security protocol that must match for a connection to match this rule. A value of IPsec, TLS, or SSH indicates a specific type of cryptographic protection. None indicates that there is no recognized cryptographic protection for the connection. This is a required field.

ZERTTLSProtocol

The inline specification of a ZERTTLSProtocol statement. The specification contains one or more TLS or SSL protocol versions.

ZERTTLSProtocolRef

The name of a globally defined ZERTTLSProtocol statement.

ZERTSSHProtocol

The inline specification of a ZERTSSHProtocol statement. The specification contains one or more SSH protocol versions.

ZERTSSHProtocolRef

The name of a globally defined ZERTSSHProtocol statement.

ZERTSymmetricEncryption

An inline specification of a ZERTSymmetricEncryption statement. The specification contains one or more symmetric encryption algorithms.

ZERTSymmetricEncryptionRef

The name of a globally defined ZERTSymmetricEncryption statement.

ZERTMessageAuthentication

An inline specification of a ZERTMessageAuthentication statement. The specification contains one or more message authentication algorithms.

ZERTMessageAuthenticationRef

The name of a globally defined ZERTMessageAuthentication statement.

ZERTKeyExchange

An inline specification of a ZERTKeyExchange statement. The specification contains one or more key exchange algorithms.

ZERTKeyExchangeRef

The name of a globally defined ZERTKeyExchange statement.

IpTimeCondition

An inline specification of an IpTimeCondition statement. There is a limit of 25 IpTimeCondition specifications in the ZERTRule statement.

IpTimeConditionRef

The name of a globally defined IpTimeCondition statement. There is a limit of 25 IpTimeCondition references in the ZERTRule statement.

ZERTActionRef

The name of a globally defined ZERTAction statement which contains the actions that should be taken for a connection that matches the conditions in the rule.

Restrictions:

- For a ZERTRule with SecurityProtocol TLS, ZERTSSHProtocol and ZERTSSHProtocolRef are not relevant and configuring either of them for the rule will be treated as an error.
- For a ZERTRule with SecurityProtocol SSH, ZERTTLSProtocol and ZERTTLSProtocolRef are not relevant and configuring either of them for the rule will be treated as an error.
- For a ZERTRule with SecurityProtocol IPsec, ZERTTLSProtocol, ZERTTLSProtocolRef, ZERTSSHProtocol, ZERTSSHProtocolRef, ZERTKeyExchange, and ZERTKeyExchangeRef are not relevant and configuring any of them for the rule will be treated as an error.
- For a ZERTRule with SecurityProtocol None, ZERTSymmetricEncryption, ZERTSymmetricEncryptionRef, ZERTMessageAuthentication, ZERTMessageAuthenticationRef, ZERTTLSProtocol, ZERTTLSProtocolRef, ZERTSSHProtocol, ZERTSSHProtocolRef, ZERTKeyExchange, and ZERTKeyExchangeRef are not relevant and configuring any of them for the rule will be treated as an error.

ZERTSSHProtocol statement

Use the ZERTSSHProtocol statement to specify one or more SSH protocol versions. A connection must be protected using one of the specified versions for this rule to match and the action to be performed.

Syntax

Place Braces and Parameters on Separate Lines

ZERTSSHProtocol Parameters

Parameters

name

A string 1 - 32 characters in length specifying the name of this ZERTSSHProtocol statement.

Rule: If this ZERTSSHProtocol statement is not specified inline within another statement, a name value must be provided. If a name is not specified for an inline ZERTSSHProtocol statement, a nonpersistent system name is created.

SSHProtocol

Specify a SSH version. The default is Any.

Restrictions:

- This statement can only be referenced by a ZERTRule with SecurityProtocol SSH.
- If SSHProtocol "Any" is configured for the ZERTSSHProtocol statement, the statement cannot contain another SSHProtocol parameter for a specific SSH version.

ZERTSymmetricEncryption statement

Use the ZERTSymmetricEncryption statement to specify one or more symmetric encryption algorithms. A connection must be protected using one of the specified symmetric encryption algorithms for this rule to match and the action to be performed.

Syntax

Place Braces and Parameters on Separate Lines

ZERTSymmetricEncryption Parameters

Parameters

name

A string 1 - 32 characters in length specifying the name of this ZERTSymmetriEncryption statement.

Rule: If this ZERTSymmetricEncryption statement is not specified inline within another statement, a name value must be provided. If a name is not specified for an inline ZERTSymmetricEncryption statement, a nonpersistent system name is created.

SymmetricEncryption

Specify a symmetric encryption algorithm. The default is Any.

Tip: For a ZERTRule with SecurityProtocol IPsec, the list of symmetric encryption algorithms describes phase 2 tunnel protection.

Restrictions:

- This statement can be referenced by a ZERTRule with SecurityProtocol TLS, SSH, or IPsec.
- If SymmetricEncryption Any is configured for the ZERTSymmetricEncryption statement, the statement cannot contain another SymmetricEncryption parameter for a specific algorithm or None.

ZERTTLSProtocol statement

Use ZERTTLSProtocol statement to specify one or more TLS protocol versions. A connection must be protected using one of the specified versions for this rule to match and the action to be performed.

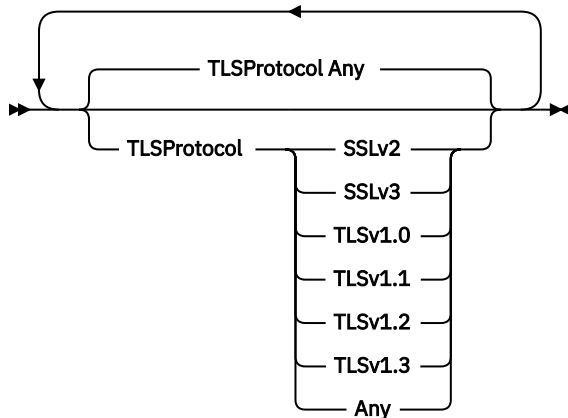

Syntax

Place Braces and Parameters on Separate Lines

ZERTTLSProtocol Parameters

Parameters

name

A string 1 - 32 characters in length specifying the name of this ZERTTLSProtocol statement.

Rule: If this ZERTTLSProtocol statement is not specified inline within another statement, a name value must be provided. If a name is not specified for an inline ZERTTLSProtocol statement, a nonpersistent system name is created.

TLSProtocol

Specify a TLS version. The default is Any.

Restrictions:

- This statement can only be referenced by a ZERTRule with SecurityProtocol TLS.
- If TLSProtocol "Any" is configured for the ZERTTLSProtocol statement, the statement cannot contain another TLSProtocol parameter for a specific TLS version.

Reusable policy statements

This topic contains information about the following reusable policy statements:

- [“IpAddr statement” on page 1122](#)
- [“IpAddrGroup statement” on page 1123](#)
- [“IpAddrSet statement” on page 1124](#)
- [“IpOptionGroup statement” on page 1125](#)
- [“IpOptionRange statement” on page 1126](#)
- [“IpProtocolGroup statement” on page 1127](#)
- [“IpProtocolRange statement” on page 1127](#)
- [“IpTimeCondition statement” on page 1128](#)
- [“Ipv6NextHdrGroup statement” on page 1130](#)
- [“Ipv6NextHdrRange statement” on page 1131](#)
- [“PortGroup statement” on page 1131](#)
- [“PortRange statement” on page 1132](#)
- [“TrafficDescriptor statement” on page 1133](#)
- [“TrafficDescriptorGroup statement” on page 1135](#)

IpAddr statement

Use the IpAddr statement to encapsulate a single IP address specification. It can be referenced from any statement that requires a single address specification. It can also be referenced from an IpAddrGroup statement.

Syntax

Put Braces and Parameters on Separate Lines

Parameters

name

A string 1 - 32 characters in length specifying the name of this IpAddr statement.

Rule: If this IpAddr statement is not specified inline within another statement, a *name* value must be provided. If a name is not specified for an inline IpAddr statement, a nonpersistent system name is created.

Addr

A single IP address.

Rules for AT-TLS policies:

- If the IP address is IPv6, it cannot be an IPv4-mapped IPv6 address (in hexadecimal or dotted decimal format) or an IPv6 address with the reserved prefix ::/96. If the IPv6 address is one of these two types, an error message is logged.
- IPv6 policy is installed but is not enforceable in a stack that is not IPv6 enabled.

Rules for IPSec policies:

- IPv4-mapped IPv6 addresses and IPv6 addresses with the reserved prefix ::/96 are valid only for IP filter rules and for the Identity parameter on local and remote security end points. If the IPv6 address is one of these types for any other IPSec policies, an error message is logged.
- IPv6 policy is installed but is not enforceable in a stack that is not IPv6 enabled.

Rules for IDS policies:

- If the IP address is an IPv6 address, it cannot be an IPv4-mapped IPv6 address (in hexadecimal or dotted decimal format) or an IPv6 address with the reserved prefix ::/96. If the IPv6 address is one of these types, an error message is logged.
- IPv6 policy is installed but is not enforceable in a stack that is not IPv6 enabled.

Rules for Routing policies:

- If the IP address is an IPv6 address, it cannot be an IPv4-mapped address in hexadecimal or dotted decimal format or an IP address with the reserved prefix ::/96. If the IPv6 address is one of these types, then an error message is logged.
- IPv6 policy is installed but is not enforceable in a stack that is not IPv6 enabled.

Rules for ZERT policies:

- If the IP address is IPv6, it cannot be an IPv4-mapped IPv6 address (in hexadecimal or dotted decimal format) or an IPv6 address with the reserved prefix ::/96. If the IPv6 address is one of these two types, an error message is logged.
- IPv6 policy is installed but is not enforceable in a stack that is not IPv6 enabled.

Restriction:

- This statement is not available for use with QoS policies.

IpAddrGroup statement

Use the IpAddrGroup statement to define an IP address group. An IpAddrGroup statement identifies a set of IP specifications that make up the IP address group.

Syntax

➤ IpAddrGroup — *name* — Put Braces and Parameters on Separate Lines ➤

Put Braces and Parameters on Separate Lines

Parameters

name

A string 1 - 32 characters in length specifying the name of this IP address group.

IpAddr

An inline specification of an IpAddr statement to be included in this group.

IpAddrRef

The name of a globally defined IpAddr statement.

IpAddrSet

An inline specification of an IpAddrSet statement to be included in this group.

IpAddrSetRef

The name of a globally defined IpAddrSet statement.

Result for AT-TLS policies:

When an IpAddrGroup statement contains non-continuous ranges of IP addresses, Policy Agent cannot merge these conditions into a single condition. The group's ranges are displayed by *pasearch*, as configured, with the summary condition equal to the lowest *from* value in the group to the highest *to* value in the group. If an IP address of 0.0.0.0 exists in an IpAddrGroup statement, the summary condition for this attribute is set to All. When an IpAddrGroup statement contains a mixture of IPv4 and IPv6 addresses, a summary condition cannot be created. The group's ranges are displayed by *pasearch*, as configured, with a summary condition for this attribute of All.

Result for Routing policies:

When an IpAddrGroup statement contains non-continuous ranges of IP addresses, Policy Agent cannot merge these conditions into a single condition. The ranges of the group are displayed by *pasearch*, as configured, with the summary condition equal to the lowest *from* value in the group to the highest *to* value in the group. If an IP address of 0.0.0.0 exists in an IpAddrGroup statement, the summary condition for this attribute is set to All. When an IpAddrGroup statement contains a mixture of IPv4 and IPv6 addresses, a summary condition cannot be created. The ranges of the group are displayed by *pasearch*, as configured, with a summary condition for this attribute of All.

Rules for ZERT policies:

- If the IP address is IPv6, it cannot be an IPv4-mapped IPv6 address (in hexadecimal or dotted decimal format) or an IPv6 address with the reserved prefix `::/96`. If the IPv6 address is one of these two types, an error message is logged.
- IPv6 policy is installed but is not enforceable in a stack that is not IPv6 enabled.

Rule: For IPsec, all addresses defined within this address group must be in the same address family (IPv4 or IPv6).

IpAddrSet statement

Use the IpAddrSet statement to encapsulate either a prefix or range of IP address specifications. It can be referenced from any statement that allows for a set specification of IP addresses.

Syntax

Put Braces and Parameters on Separate Lines

Parameters

name

A string 1 - 32 characters in length specifying the name of this IpAddrSet statement.

Rule: If this IpAddrSet statement is not specified inline within another statement, a *name* value must be provided. If a name is not specified for an inline IpAddrSet statement, a nonpersistent system name is created.

Prefix

A prefix IP address specification.

The *prefixLength* value is the number of unmasked leading bits in the *ipaddress* value. The *prefixLength* value can be in the range 0 - 32 for IPv4 addresses and from 0 - 128 for IPv6 addresses. A packet matches this condition if its unmasked bits are identical to the unmasked bits defined.

Range

A range of IP addresses.

Rules for AT-TLS policies:

- If the IP address is an IPv6 address, it cannot be an IPv4-mapped IPv6 address in hexadecimal or dotted decimal format or an IPv6 address with the reserved prefix `::/96`. If the IPv6 address is one of these types, an error message is logged.
- IPv6 policy is installed but is not enforceable in a stack that is not IPv6 enabled.

Rules for IPSec policies:

- IPv4-mapped IPv6 addresses and IPv6 addresses with the reserved prefix `::/96` are valid only for IP filter rules and for the Identity parameter on local and remote security end points. If the IPv6 address is one of these types for any other IPSec policies, an error message is logged.
- IPv6 policy is installed, but is not enforceable in a stack that is not IPv6 enabled.

Rules for IDS policies:

- If the IP address is an IPv6 address, it cannot be an IPv4-mapped IPv6 address in hexadecimal or dotted decimal format or an IPv6 address with the reserved prefix `::/96`. If the IPv6 address is one of these types, an error message is logged.
- IPv6 policy is installed but is not enforceable in a stack that is not IPv6 enabled.

Rules for Routing policies:

- If the IP address is an IPv6 address, it cannot be an IPv4-mapped address in hexadecimal or dotted decimal format or an IP address with the reserved prefix `::/96`. If the IPv6 address is one of these types, then an error message is logged.
- IPv6 policy is installed but is not enforceable in a stack that is not IPv6 enabled.

Rules for ZERT policies:

- If the IP address is IPv6, it cannot be an IPv4-mapped IPv6 address (in hexadecimal or dotted decimal format) or an IPv6 address with the reserved prefix `::/96`. If the IPv6 address is one of these two types, an error message is logged.
- IPv6 policy is installed but is not enforceable in a stack that is not IPv6 enabled.

Restriction:

- This statement is not available for use with QoS policies.

IpOptionGroup statement

Use the IpOptionGroup statement to define an IP option group. An IpOptionGroup statement identifies a set of IP option specifications that make up the IP option group.

Restriction: This statement is available for use only with IDS configuration policies.

Syntax

➤➤ IpOptionGroup — *name* — Put Braces and Parameters on Separate Lines ➤➤

Put Braces and Parameters on Separate Lines

IpOptionGroup Parameters

Parameters

name

A string 1 - 32 characters in length for the name of this `IpOptionGroup`.

IpOptionRange

An inline specification of an `IpOptionRange` statement to be included in this group.

IpOptionRangeRef

The name of a globally defined `IpOptionRange` statement.

IpOptionRange statement

Use the `IpOptionRange` statement to encapsulate a single IP option or range of IP options. It can be referenced from any statement that allows for a set specification of IP options.

Restriction: This statement is available for use only with IDS configuration policies.

Syntax

➤➤ IpOptionRange — *name* — Put Braces and Parameters on Separate Lines ➤➤

Put Braces and Parameters on Separate Lines

IpOptionRange Parameters

Parameters

name

A string 1 - 32 characters in length specifying the name of this `IpOptionRange` statement.

Rule: If this IPOptionRange statement is not specified inline within another statement, *name* must be provided. If a name is not specified for an inline IPOptionRange statement, a nonpersistent system name is created.

IpOption

A single IP option or range of options.

Valid values for *n* are 1 - 255. While there are 255 possible valid IP options, only a few are in common usage today. If an *m* value is specified, it must be greater than or equal to *n* and less than 256.

Restriction: For IDS policy attack types RESTRICTED_IPV6_DST_OPTIONS and RESTRICTED_IPV6_HOP_OPTIONS, you cannot restrict options 0 (Pad1) or 1 (PadN). They are always allowed.

IpProtocolGroup statement

Use the IpProtocolGroup statement to define a protocol group. An IpProtocolGroup statement identifies a set of protocol specifications that make up the protocol group.

Restriction: This statement is available for use only with IDS configuration policies.

Syntax

➤ IpProtocolGroup — *name* — Put Braces and Parameters on Separate Lines ➤

Put Braces and Parameters on Separate Lines

IpProtocolGroup Parameters

Parameters

name

A string 1 - 32 characters in length specifying the name of this IpProtocolGroup.

IpProtocolRange

An inline specification of an IpProtocolRange statement to be included in this group.

IpProtocolRangeRef

The name of a globally defined IpProtocolRange statement.

IpProtocolRange statement

Use the IpProtocolRange statement to encapsulate a single protocol or range of protocols. This statement can be referenced from any statement that allows for a set specification of protocols.

Restriction: This statement is available for use only with IDS configuration policies.

Syntax

➤ IpProtocolRange — Put Braces and Parameters on Separate Lines ➤

Parameters

name

A string 1 -32 characters in length specifying the name of this IpProtocolRange statement.

Rule: If this IpProtocolRange statement is not specified inline within another statement, a *name* value must be provided. If a name is not specified for an inline IpProtocolRange statement, a nonpersistent system name is created.

IpProtocol

A single protocol or range of protocols.

Valid values for *n* are in the range 0 - 255. A protocol range consists of one or more consecutive protocol numbers. If an *m* value is specified, it must be greater than or equal to *n* and less than 256.

Rule: You must include a blank, a colon (:), or a dash (-) as a delimiter.

IpTimeCondition statement

Use the IpTimeCondition statement to define when the associated rule or action is in effect. All conditions on the IpTimeCondition statement must be true for the associated rule or action to be in effect.

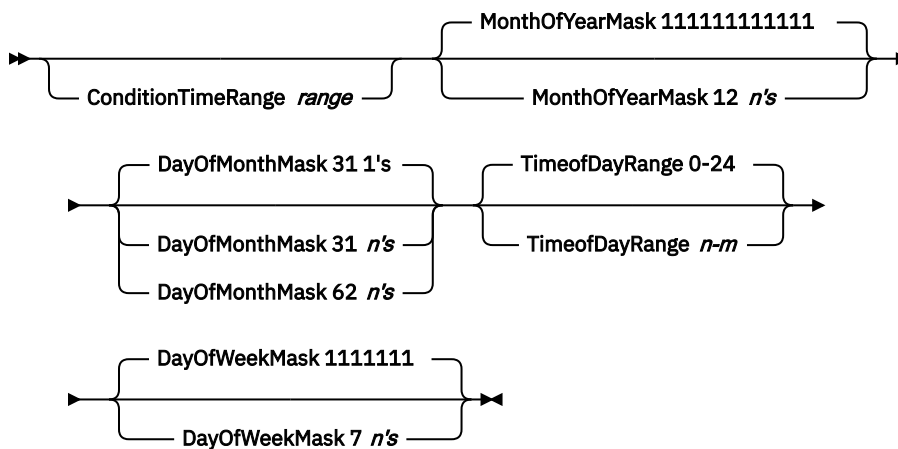

Syntax

Put Braces and Parameters on Separate Lines

IpTimeCondition Parameters

Parameters

name

A string 1 - 32 characters in length specifying the name of this IpTimeCondition statement.

Rule: If this IpTimeCondition statement is not specified inline within another statement, a *name* value must be provided. If a name is not specified for an inline IpTimeCondition, a nonpersistent system name is created.

ConditionTimeRange

This field specifies an overall range of calendar dates and times over which a policy rule or action is active. It is a string consisting of a start date and time, then a colon (:) followed by an end date and time. The first date indicates the beginning of the range, and the second date indicates the end of the range. Thus, the second date and time must be later than the first. Dates are expressed as substrings of the form `yyyymmddhhmmss`. Seconds are rounded to the nearest minute. Because all dates and times are converted internally to the Posix time format, do not specify dates and times before the start of the Posix epoch, which is January 1, 1970, 00:00:00 UTC.

For example, `20010101080000:20010131120000` is January 1, 2001, 0800 through January 31, 2001, noon.

Tips:

- The internal Posix time format is expressed in terms of seconds since the epoch, which means the time wraps sometime early in the year 2038. Therefore, do not specify dates or times later than this.
- All dates and times refer to local time.

MonthOfYearMask

This string field specifies which months of the year the policy rule or action is valid. This attribute is formatted as a string containing 12 0's and 1's, where the 1's identify the months (beginning with January) in which the policy rule or action is valid. The value `000010010000`, for example, indicates that a policy rule or action is valid only in the months May and August. The default is that the policy assumes that it is valid for all twelve months.

DayOfMonthMask

This string field specifies which days of the month the policy rule or action is valid. The day of month mask can be 31 or 62 bits. The second 31 bits specify the days of the month in reverse order. Bit 32 is the last day of the month, bit 33 is the second from last day of month, and so on. This attribute is formatted as a string containing 31 or 62 0's and 1's, where the 1's identify the days of the month in which the policy rule or action is valid. The value `11100000000000000000000000000000`, for example, indicates that a policy rule or action is valid only on the first three days of each month. For months with less than 31 days, the digits corresponding to the missing days are ignored.

The default is every day of the month.

DayOfWeekMask

A mask of seven bits representing the days in a week (Sunday through Saturday) that this policy rule or action is active. For example, 0111110 represents weekdays. The default is every day of the week.

TimeOfDayRange

A time interval that indicates the time of day, expressed in local time, during which this policy rule or action is active. You can specify hours and optional minutes, separated by a colon. The values 0 and 24 both indicate midnight. The interval consists of two values separated by a dash. If the second value is smaller than or equal to the first value, then the interval spans midnight. For example, the following statement results in this policy rule or action being active from midnight until 8:30 AM:

```
TimeOfDayRange 0-8:30
```

The following statement results in this policy rule or action being active from 5:30 PM until 8:30 AM:

```
TimeOfDayRange 17:30-8:30
```

Ipv6NextHdrGroup statement

Use the Ipv6NextHdrGroup statement to define an IPv6 next-header group. An Ipv6NextHdrGroup statement identifies a set of IPv6 next-header specifications that make up the IPv6 next-header group.

Restrictions:

- This statement is available for use only with IDS configuration policies.
- This statement is valid only for V1R13 and later releases. See [“General syntax rules for Policy Agent” on page 820](#) for details.

Syntax

➤ Ipv6NextHdrGroup — *name* — Put Braces and Parameters on Separate Lines ➤

Put Braces and Parameters on Separate Lines

Ipv6NextHdrGroup Parameters

Parameters

name

A string 1 - 32 characters in length that specifies the name of this Ipv6NextHdrGroup statement.

Ipv6NextHdrRange

An inline specification of an Ipv6NextHdrRange statement to be included in this group.

Ipv6NextHdrRangeRef

The name of a globally defined Ipv6NextHdrRange statement.

Ipv6NextHdrRange statement

Use the Ipv6NextHdrRange statement to encapsulate a single IPv6 next-header value or a range of IPv6 next-header values. This statement can be referenced from any statement that allows for a set specification of IPv6 next-header values.

Restrictions:

- This statement is available for use only with IDS configuration policies.
- This statement is valid only for V1R13 and later releases. See [“General syntax rules for Policy Agent”](#) on page 820 for details.

Syntax

Put Braces and Parameters on Separate Lines

Ipv6NextHdrRange Parameters

Parameters

name

A string 1 - 32 characters in length that specifies the name of this Ipv6NextHdrRange statement.

Rule: If you do not specify this Ipv6NextHdrRange statement inline within another statement, you must provide a *name*. If you do not specify a name for an inline Ipv6NextHdrRange statement, a nonpersistent system name is created.

Ipv6NextHdr

A single IPv6 next-header value or a range of IPv6 next-header values. The value in the next-header field of an IPv6 header or extension header identifies the next-header in the packet, either an upper layer protocol header (such as a TCP or UDP header) or an extension header (such as a fragmentation or routing header).

Valid values for *n* are in the range 0 - 255. If you specify an *m* value, it must be greater than or equal to *n* and less than 256.

Rule: You must include a blank, a colon (:), or a dash (-) as a delimiter.

PortGroup statement

Use the PortGroup statement to define a port group. A PortGroup statement identifies a set of port specifications that make up the port group.

Syntax

Put Braces and Parameters on Separate Lines

Parameters

name

A string 1 - 32 characters in length specifying the name of this Port group.

PortRange

An inline specification of a PortRange statement to be included in this group.

PortRangeRef

The name of a globally defined PortRange.

Restriction: This statement is available for use only with IDS configuration and AT-TLS policies.

Tip: When a PortGroup contains non-continuous ranges of port numbers, Policy Agent cannot merge these conditions into a single condition. The group's ranges are displayed by pasearch, as configured, with the summary condition for each of these respective attributes equal to the lowest *from* value in the group to the highest *to* value in the group. If a Port of value 0 exists in a PortGroup, the summary condition for this attribute is set to the range 0 - 0.

PortRange statement

Use the PortRange statement to encapsulate a single port or range of ports. It can be referenced from any statement that allows for a set specification of ports.

Syntax

Put Braces and Parameters on Separate Lines

Parameters

name

A string 1 - 32 characters in length specifying the name of this PortRange statement.

Rule: If this PortRange statement is not specified inline within another statement, a *name* value must be provided. If a name is not specified for an inline PortRange statement, a nonpersistent system name is created.

Port

A single port or range of ports.

Valid values for *n* are in the range 0 - 65 535. If 0 is specified for *n*, then any port can be used. If *n* is specified as the beginning value for a range, then 0 is not a valid value.

If an *m* value is specified, it must be greater than or equal to *n* and less than 65 536.

Rule: Include a blank, a colon (:), or a dash (-) as a delimiter.

Restrictions:

- For IDSAttackCondition the only valid port values for *n* are 1 - 65 535.
- PortRange is available for use only with IDS configuration and AT-TLS policies.

TrafficDescriptor statement

Use the TrafficDescriptor statement to describe IP traffic in terms of one or more of the following characteristics: IP protocol, source and destination port values, job name, NetAccess security zone, and multilevel-security (MLS) label.

Restriction: The TrafficDescriptor statement is available for use only with Routing policies.

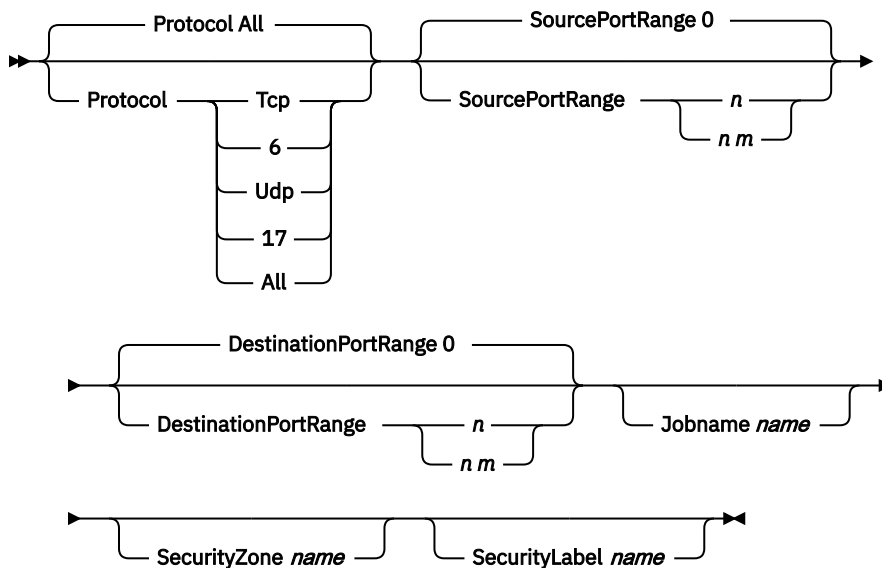

Syntax

Put Braces and Parameters on Separate Lines

TrafficDescriptor Parameters

Parameters

name

A string 1 - 32 characters in length specifying the name of this TrafficDescriptor statement.

Rule: If this TrafficDescriptor statement is not specified inline within another statement, a *name* value must be provided.

If a name is not specified for an inline TrafficDescriptor statement, a nonpersistent system name is created.

Protocol

A protocol that must be contained in an IP packet for the rule's action to be performed.

TCP or 6

Indicates TCP protocol.

UDP or 17

Indicates that the UDP protocol must be in the packet.

All

Indicates that all protocols that are relevant to the policy type that references the TrafficDescriptor statement must be in the packet. This is the default value.

Rule: For the Routing policy type, the relevant protocols are TCP and UDP.

SourcePortRange

A source port that must be contained in a TCP or UDP packet for the rule's action to be performed.

Valid values for *n* are in the range 0 - 65 535. If 0 is specified for *n*, the rule applies to any source port. If *n* is specified as the beginning value for a range, then 0 is not a valid value.

If an *m* value is specified, it must be greater than or equal to the *n* value and less than 65 536.

Rule: Include a blank, a colon (:), or a dash (-) as a delimiter.

Restrictions:

- The SourcePortRange value is used only as a selector for a TCP or UDP packet. If the value TCP or UDP is specified for the Protocol parameter, the SourcePortRange parameter is further restricted to the protocol specified.
- For Routing policies, the value specified for the SourcePortRange parameter is the source port that must be contained in an outbound TCP or UDP packet.

DestinationPortRange

A destination port that must be contained in a TCP or UDP packet for the rule's action to be performed.

Valid values for *n* are in the range 0 - 65 535. If 0 is specified for *n*, then the rule applies to any destination port. If *n* is specified as the beginning value for a range, then 0 is not a valid value.

If an *m* value is specified, it must be greater than or equal to the *n* value and less than 65 536.

Rule: Include a blank, a colon (:), or a dash (-) as a delimiter.

Restrictions:

- The DestinationPortRange value is used only as a selector for a TCP or UDP packet. If the value TCP or UDP is specified for the Protocol parameter, the DestinationPortRange is further restricted to the protocol specified.
- For Routing policies, the value specified for the DestinationPortRange parameter is the destination port that must be contained in an outbound TCP or UDP packet.

Jobname

The *name* value specifies the job name of the application. The *name* value can be up to 8 characters in length. A trailing asterisk indicates a wildcard specification. The specified name is not case sensitive, and is translated to uppercase before being compared.

SecurityZone

The *name* value specifies the NetAccess security zone that an IP packet must match for the rule's action to be performed. The *name* value can be up to 8 characters in length. The specified name is not case sensitive.

For Routing policies, the *name* value specifies the NetAccess security zone that an outbound IP packet must match. The outbound packet's destination IP address is used to determine the packet's NetAccess security zone in the NetAccess table defined in the TCP/IP profile. For more information about network access control, see [“NETACCESS statement” on page 181](#).

SecurityLabel

The *name* value specifies the MLS security label that an IP packet must match for the rule's action to be performed. The *name* value can be up to 8 characters in length. The specified name is not case sensitive.

For Routing policies, the *name* value specifies the MLS security label that an outbound IP packet must match. The outbound packet's destination IP address is used to determine the packet's NetAccess security zone in the NetAccess table defined in the TCP/IP profile. The MLS security label is the label associated with the NetAccess zone. For more information, see the [TCP/IP networking in a multilevel-secure environment](#) information in [z/OS Communications Server: IP Configuration Guide](#).

TrafficDescriptorGroup statement

Use the TrafficDescriptorGroup statement to define a traffic descriptor group. A TrafficDescriptorGroup statement identifies a set of TrafficDescriptor statements that make up the traffic descriptor group

Restriction: The TrafficDescriptorGroup statement is available for use only with Routing policies.

Syntax

➤ TrafficDescriptorGroup — *name* — Put Braces and Parameters on Separate Lines ➤

Put Braces and Parameters on Separate Lines

Parameters

name

A string 1 - 32 characters in length specifying the name of this TrafficDescriptorGroup statement.

TrafficDescriptor

An inline specification of a TrafficDescriptor statement to be included in this group.

TrafficDescriptorRef

The name of a globally defined TrafficDescriptor statement to be included in the group.

Policy Agent search order

The search order for accessing PAGENT.CONF information is as follows. The first file found in the search order is used.

1. File or data set specified with the -c startup option
2. File or data set specified with the PAGENT_CONFIG_FILE environment variable
3. /etc/pagent.conf

Starting Policy Agent from the z/OS shell

The Policy Agent executable program resides in /usr/lpp/tcpip/sbin. There is also a link from /usr/sbin. Make sure the PATH statement contains either /usr/sbin or /usr/lpp/tcpip/sbin.

The Policy Agent requires access to one or more DLLs at runtime. The LIBPATH environment variable must be set to include the /usr/lib directory, which normally includes all the required DLLs.

In order for policy time specifications to be properly acted upon, the TZ environment variable needs to be set to local time.

Set the LIBPATH and TZ environment variables as follows:

Export the LIBPATH and TZ environment variables before starting the Policy Agent. Use /etc/profile or in .profile in the HOME directory. For example, in the Eastern time zone in the United States:

```
export LIBPATH=/usr/lib
export TZ=EST5EDT4
```

See [z/OS Language Environment Programming Guide](#) for more information about specifying run time options and environment variables. Also, see [z/OS UNIX System Services Command Reference](#) for details about setting the LIBPATH and TZ environment variables.

►► pagent ►►

Guideline: The options can be in either upper- or lowercase (for example, C or c).

Rule: To avoid interfering with the shell session, run Policy Agent in the background. To run Policy Agent in the background, add a trailing & to the command line used to start Policy Agent.

Parameters

-c/C

The -c/C option allows a policy configuration file name to be specified. If it is not specified, the configuration file is located using the search order.

This value can be an z/OS UNIX or MVS data set.

The z/OS UNIX file or MVS data set is specified by the -c startup option. The syntax for a z/OS UNIX file is '/dir/file' and the syntax for an MVS data set is "'/MVS.DATASET.NAME'".

Tip: Note the differences in the single and double quotation marks.

-d/D

When -d is specified, all debug messages are logged in the Policy Agent log file. If -d is not used, log messages are written to the Policy Agent log file as specified by the LogLevel configuration statement. The log file should be the first place checked for error messages.

n is an integer that specifies the level of debugging. Specify a desired debug level or a combination of levels. If this start option is absent, the default level is 0. To combine debug levels, add debug level numbers. For example, to request base messages (level 1) and sysplex summary messages (Level 4), request a debug level of 5 (for example, -d 5).

0

None. No debug messages are logged. This is the default.

1

Base. The Policy Agent logs internal debug information.

When this level is selected, the Policy Agent also uses the maximum LogLevel value, regardless of what is configured.

2

LDAP. The Policy Agent logs information about each LDAP object attribute that is processed.

4

Sysplex summary. The Policy Agent logs summary information about performance monitor QoS fraction calculations at target stacks.

8

Sysplex detail. The Policy Agent logs detailed information about performance monitor QoS fraction calculations at target stacks, and additional sysplex distributor information.

16

Memory trace. The Policy Agent logs inline details of all memory allocation and free requests. This debug level is independent of the `-m` startup option.

32

Policy install trace. The Policy Agent logs details of all policies as the policies are installed in the TCP/IP stack.

64

Lock trace. The Policy Agent logs information about locks.

128

Remote connection trace. The Policy Agent logs details about remote PAPI connections on the policy server and about connections to the policy server on the policy client.

256

Discovery connection trace. The Policy Agent logs details about requests to discover TCP/IP profile information from import requestors.

-i/I

When specified, the Policy Agent monitors its local files (all configuration files) in real time for changes. The time interval configured on the `TcpImage` statement is also used to monitor configuration files and the LDAP server for updates. Use of the `-i/I` option provides more timely updating of policy statements when a configuration file is changed. Change the configuration file to cause an immediate refresh of policy from the LDAP server, which causes the file to be reread. If the file is configured to read policy from the LDAP server, Policy Agent does so at that time.

Restrictions:

- Dynamic monitoring for file updates using the `-i` startup option is not supported for files configured with the `DynamicConfigPolicyLoad` statement.
- Dynamic monitoring for file updates using the `-i` startup option is supported only for z/OS UNIX files; MVS data sets are not monitored for changes (these files are reread at each refresh interval).
- Dynamic monitoring for file updates using the `-i` startup option is not supported for ZERT policies.

-t/T

The `-t/T` options specify whether to turn on LDAP client debugging. The following levels are supported:

0

No LDAP client debugging. This is the default.

1

This level turns on LDAP client debugging.

Tip: The destination of LDAP client debug messages is `stderr`.

This is controlled by the LDAP client library, not the Policy Agent. This turns on the following LDAP DEBUG Options:

- `LDAP_DEBUG_TRACE`
- `LDAP_DEBUG_PACKETS`
- `LDAP_DEBUG_ARGS`
- `LDAP_DEBUG_CONNS`
- `LDAP_DEBUG_BER`
- `LDAP_DEBUG_FILTER`
- `LDAP_DEBUG_MESSAGE`
- `LDAP_DEBUG_STATS`

- LDAP_DEBUG_THREAD
- LDAP_DEBUG_PARSE
- LDAP_DEBUG_PERFORMANCE
- LDAP_DEBUG_REFERRAL
- LDAP_DEBUG_ERROR

For details about debug options, see *z/OS Security Server LDAP Client Application Development Guide and Reference*.

Restriction: If Policy Agent was started with the trace option disabled, then the output destination of stderr is closed. This option cannot later be enabled by using the MODIFY command.

-l/L logfile

The `-l/L` option can be used to specify the destination of the log output file. Either SYSLOGD or a z/OS UNIX file can be specified. If you specify SYSLOGD, you can take advantage of a centralized logging mechanism. The environment variable PAGENT_LOG_FILE also specifies the destination of the log file, using the same format as this option. The `-l/-L` option overrides the PAGENT_LOG_FILE environment variable. Another environment variable, PAGENT_LOG_FILE_CONTROL, specifies the number and size of log files (if SYSLOGD is not specified). The format is: PAGENT_LOG_FILE_CONTROL=x,y where x is the log file size (kilobytes). A maximum value of 1 000 000 can be specified. y is the number of log files. The default is 3 log files, each 300 kilobytes in size.

The default is /tmp/pagent.log.

Result: If for some reason Policy Agent cannot read the start options, then it does not have a log file destination and Policy Agent might fail to open a z/OS UNIX log file. In these situations, Policy Agent logs error messages to the syslog daemon and exits abnormally.

If you run Policy Agent with a nonzero UID and you are using a z/OS UNIX log file, be sure to perform the following tasks:

- Specify the file permissions as either 776 or 766.
- Ensure that the syslog daemon is not configured to log the same z/OS UNIX file. The syslog daemon runs with UID 0 so Policy Agent might not be able to access its log file if syslogd creates the file before Policy Agent starts.

-m/M n

When specified, the Policy Agent records all memory allocation and free requests in a buffer. The number of entries in this buffer is specified on the `-m` option. The minimum value is 1 000 and the maximum value is 25 000. Values specified outside of this range are rounded up or down as needed. The number of entries in the buffer determines how many concurrent memory allocations can be recorded.

The memory request buffer can be used in two ways:

- To provide a snapshot of Policy Agent memory allocations, by using the MODIFY MEMTRC command. See [z/OS Communications Server: IP System Administrator's Commands](#) and [z/OS Communications Server: IP Diagnosis Guide](#) for more information about this command.
- To detect memory leakage by the Policy Agent. Memory leakage can only be determined when Policy Agent terminates. At the end of termination, after all memory free requests have been processed, any entries left in the memory request buffer are by definition memory leaks. If the `-m` option was specified, Policy Agent logs the contents of the memory request buffer at the end of Policy Agent termination.

If the number of entries specified on the `-m` option is too small to contain the total number of concurrent memory allocations at any point in time, Policy Agent turns off the memory trace function and stops recording in the buffer. If this occurs, the contents of the buffer are not usable, and Policy Agent logs this fact along with the high water mark number of entries at termination. Increase the number of entries the next time Policy Agent is started.

If the Policy Agent cannot successfully parse the start options, log output is written to the syslog daemon (SYSLOGD).

Starting Policy Agent as a started task

Use the S PAGENT command on an MVS console or SDSF to start Policy Agent. A sample procedure is included in member EZAPAGSP in SEZAINST. All of the information regarding default locations for the configuration and log files is the same as for starting from the z/OS shell.

The Policy Agent requires access to one or more DLLs at runtime. The LIBPATH environment variable must be set to include the /usr/lib directory, which normally includes all the required DLLs.

In order for policy time specifications to be properly acted upon, the TZ environment variable needs to be set to local time.

Set the LIBPATH and TZ environment variables as follows:

- Specify LIBPATH and TZ using the ENVAR parameter on the PARM statement in the started procedure. For example:

```
// PARM=('POSIX(ON) ALL31(ON)',  
// 'ENVAR("LIBPATH=/usr/lib",  
// '"TZ=EST5EDT4")/')
```

- Export the LIBPATH and TZ environment variables in a file specified with the STDENV DD statement. For example:

```
//STDENV DD PATH='/etc/pagent.env',PATHOPTS=(ORDONLY)
```

In the /etc/pagent.env file:

```
LIBPATH=/usr/lib  
TZ=EST5EDT4
```

See [z/OS Language Environment Programming Guide](#) for more information about specifying runtime options and environment variables. See [z/OS UNIX System Services Command Reference](#) for details about setting the LIBPATH and TZ environment variables.

Below is a copy of the sample procedure:

```
//PAGENT PROC  
//*  
//* IBM Communications Server for z/OS  
//* SMP/E distribution name: EZAPAGSP  
//*  
//* 5650-ZOS Copyright IBM Corp. 1998, 2013  
//* Licensed Materials - Property of IBM  
//* "Restricted Materials of IBM"  
//* Status = CSV2R1  
//*  
//PAGENT EXEC PGM=PAGENT,REGION=0K,TIME=NOLIMIT,  
// PARM='ENVAR("_CEE_ENVFILE_S=DD:STDENV")/'  
//*  
//*** Policy Agent parameters:  
//*  
//* -c filename  
//*  
//* Specifies the MVS data set or z/OS UNIX main configuration file.  
//* The syntax for an MVS data set is "'MVS.DATASET.NAME'" and the  
//* syntax for a z/OS UNIX file is /dir/file. This start option  
//* overrides the environment variable PAGENT_CONFIG_FILE if it is  
//* specified. The default value is /etc/pagent.conf.  
//*  
//* -d n  
//*  
//* Specifies a debug level. See Communications Server IP  
//* Diagnosis for a description of the debug levels.  
//*  
//* -i  
//*  
//* Specifies that Policy Agent should read configuration files
```

```

/** immediately if they are changed.
/**
/** -t n
/**
/** Specifies the LDAP client trace level. The only supported values
/** are 1 to turn on tracing or 0 to turn off tracing.
/**
/** -l filename | SYSLOGD
/**
/** Specifies the destination of the Policy Agent log file. You
/** can specify a z/OS UNIX file name or the value SYSLOGD in
/** uppercase. SYSLOGD is recommended because it routes log output
/** to the syslog daemon. This start option overrides the environment
/** variable PAGENT_LOG_FILE if it is specified. The default value
/** is /tmp/pagent.log.
/**
/** -m n
/**
/** Specifies that Policy Agent should enable memory tracing. See
/** Communications Server IP Diagnosis for more information on
/** memory tracing.
/**
/***** Examples for specifying environment variables and parameters
/***** (parameters must extend to column 71 and be continued in
/***** column 16):
/**
/** Example 1: Environment variables inline, MVS config data set
/**
/**      PARM=('ENVAR("LIBPATH=/usr/lib","TZ=EST5EDT")/-c //' 'USER.TCIP
/**          ARMS(PAGENT)' ' -l SYSLOGD')
/**
/** Example 2: Environment variables inline, UNIX config file
/**
/**      PARM=('ENVAR("LIBPATH=/usr/lib","TZ=EST5EDT")/-c /etc/pagent3.
/**          conf -l SYSLOGD')
/**
/** Example 3: Environment variables in STDENV DD
/**
/**      PARM='ENVAR("_CEE_ENVFILE_S=DD:STDENV")/'
/**
/** For this method, the STDENV DD statement below must be
/** changed to point to a MVS data set or UNIX file containing
/** settings for any environment variables. For example, it should
/** contain at least LIBPATH and TZ (unless you choose to specify TZ
/** in a different fashion), but can contain other environment
/** variables as in this example:
/**
/**      PAGENT_CONFIG_FILE=/etc/pagent2.conf
/**      PAGENT_LOG_FILE=SYSLOGD
/**      LIBPATH=/usr/lib
/**      TZ=EST5EDT
/**
/** If you want to include comments in the data set or
/** z/OS UNIX file, specify the _CEE_ENVFILE_COMMENT
/** environment variable as the first environment variable
/** in the data set or file. The value specified for
/** the _CEE_ENVFILE_COMMENT variable is the comment character.
/** For example, if you want to use the pound sign, #, as
/** the comment character, specify this as the first
/** statement:
/**      _CEE_ENVFILE_COMMENT=#
/**
/** The use of the STDENV DD statement works well when more than
/** one environment variable is specified, as there is a JCL limit
/** of 100 characters on the PARM statement.
/**
/** Note: Language Environment recommends a variable record format
/** for the STDENV file.
/**
/** You can also set the TZ environment variable for all applications
/** in the CEEPRMxx PARMLIB member. You should define the TZ
/** environment variable for all three LE option sets (CEEDOPT,
/** CEECOPT, and CELQDOPT). For example:
/**
/**      CEECOPT(ALL31(ON), ENVAR('TZ=EST5EDT')) )
/**      CEEDOPT(ALL31(ON), ENVAR('TZ=EST5EDT')) )
/**      CELQDOPT(ALL31(ON), ENVAR('TZ=EST5EDT')) )
/**
/** For more information on specifying run-time options, see z/OS
/** Language Environment Programming Guide. For details on setting
/** the LIBPATH and TZ environment variables, see z/OS UNIX System
/** Services Command Reference.

```

```

/*
//STDENV DD DUMMY
/* Sample MVS data set containing environment variables:
//STDENV DD DSN=TCPIP.PAGENT.ENV(PAGENT),DISP=SHR
/* Sample UNIX file containing environment variables:
//STDENV DD PATH='/etc/pagent.env',PATHOPTS=(ORDONLY)
/*
/* Output written to stdout and stderr goes to the data set or
/* file specified with SYSPRINT or SYSOUT, respectively. But
/* normally, PAGENT doesn't write output to stdout or stderr.
/* Instead, output is written to the log file, which is specified
/* by the -c startup option, the PAGENT_LOG_FILE environment
/* variable, or the default of /tmp/pagent.log. For severe
/* startup errors, such as incorrect startup options specified,
/* or being unable to open the log file, log output is instead
/* written to the syslog daemon, and help text is written to
/* stdout.
/*
//SYSPRINT DD SYSOUT=*
//SYSOUT DD SYSOUT=*
/*
//CEEDUMP DD SYSOUT=*,DCB=(RECFM=FB,LRECL=132,BLKSIZE=132)

```

Figure 28. PAGENT sample procedure

Restriction: When you use the environment variable _CEE_ENVFILE with an MVS data set, allocate the data set with the value RECFM=V. You should not use RECFM=F because RECFM=F causes the environment variable values to be padded with blanks.

Policy Agent environment variables

Table 86 on page 1141 provides a list of environment variables used by Policy Agent that can be tailored to a particular installation:

Table 86. Policy Agent environment variables			
Environment variable	Server, Client or Command-type application	Description	Any specific coding rules (or a link to syntax)
PAGENT_CONFIG_FILE	PAGENT	This variable points to the location of the Policy Agent configuration file or data set.	None
PAGENT_LOG_FILE	PAGENT	Policy agent should log messages to either the syslog daemon (recommended) or a z/OS UNIX file.	Default is /tmp/pagent.log
PAGENT_LOG_FILE_CONTROL	PAGENT	Control the number and size of Policy Agent log files.	

Starting the network SLAPM2 subagent from the z/OS shell

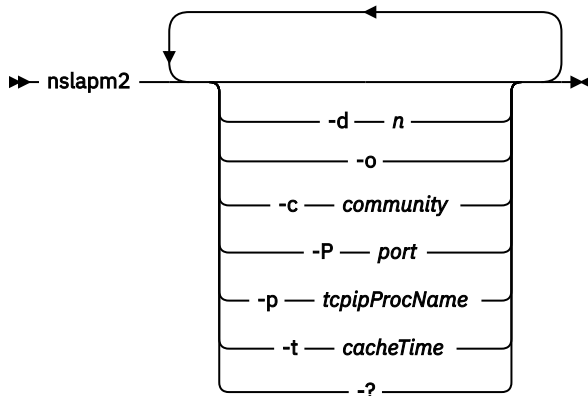

The Network SLAPM2 Subagent executable program resides in /usr/lpp/tcpip/bin. There is also a link from /bin. Ensure that the path statement (in the profile) contains either /bin or /usr/lpp/tcpip/bin.

The Network SLAPM2 subagent requires access to one or more DLLs at runtime. The LIBPATH environment variable must be set to include the /usr/lib directory, which normally includes all the required DLLs.

Export the LIBPATH environment variable before starting the subagent. Use /etc/profile or .profile in the HOME directory. For example:

```
export LIBPATH=/usr/lib
```

For more information about specifying runtime options and environment variables, see [z/OS Language Environment Programming Guide](#). For details about setting the LIBPATH environment variable, see [z/OS UNIX System Services Command Reference](#).

Parameters

-d n

Specifies the level of tracing to be started. The valid values for level are in the range 0 - 511. If the -d parameter is not specified, then a level of 3 is used, meaning all Network SLAPM2 Subagent Error, System Console and Warning Messages are traced. There are nine levels of tracing provided. Each level selected has a corresponding number. The sum of the numbers associated with each level of tracing selected is the value which should be specified as level. After the Network SLAPM2 Subagent is started, tracing options can be dynamically changed using the MVS MODIFY command. For more information about agent tracing, see [z/OS Communications Server: IP Diagnosis Guide](#).

The numbers for the trace levels are:

0

No tracing

1

Trace Network SLAPM2 Subagent Error and System Console Messages

2

Trace Network SLAPM2 Subagent Warning Message

4

Trace Network SLAPM2 Subagent Informational Message

8

Trace Network SLAPM2 Subagent Internal statistics table

16

Trace Network SLAPM2 Subagent Internal monitor table

32

Trace Network SLAPM2 Subagent Internal traps

64

Trace Network SLAPM2 Subagent Internal monitoring

128

Trace Network SLAPM2 Subagent Internal Policy Agent API

256

Trace DPIDebug()level 2

Output from the -d parameter is written to syslogd or stdout depending on the -o parameter. The debug level can be dynamically changed using a MODIFY command.

-o

Specifies that debug output is written to stdout. The default is to write to syslogd.

-c community

A string 1 - 32 characters in length used as the SNMP community name (or password) in establishing contact with the SNMP Agent. For nslapm2 to communicate with the z/OS CS SNMP Agent, the community name specified on the -c startup option must match one that is defined in a data set configured to the SNMP Agent on the -c parameter when the SNMP Agent is started.

For more information about how the community name is used to permit access to the SNMP agent, see [Step 1: Configure the SNMP agent \(OSNMPD\)](#), in [z/OS Communications Server: IP Configuration Guide](#). The default value is public.

Tip: The community name is case sensitive.

-P port

A port number in the range 1 - 65 535 used in establishing communication with the SNMP Agent. For nslapm2 to communicate with the z/OS CS SNMP Agent, the port number specified must match the port number specified on the -p parameter when the SNMP Agent is started. The default value is 161.

-p tcpipProcName

The tcpipProcName is an 8-byte procedure name that is used to start TCP/IP. If this parameter is not specified, nslapm2 uses the standard resolver configuration search order to determine this parameter.

-t cacheTime

Amount of time in seconds to elapse before rebuilding the MIB object tables. Default value is 30 seconds.

The MinimumSamplingInterval value on the Policy Agent configuration statement PolicyPerformanceCollection is used to rebuild the MIB object tables, if the cacheTime is smaller than the MinimumSamplingInterval value.

If the MinimumSamplingInterval is updated in Pagent, then the Network SLAPM2 Subagent becomes aware of the updated time the next time it rebuilds the MIB objects.

The cache Time can be dynamically changed using a MODIFY command.

The MODIFY,QUERY command can be issued to determine the value for the MinimumSamplingInterval and this cacheTime value.

-?

Display nslapm2 options help information.

Starting the network SLAPM2 subagent as a started task

Use the S NSLAPM2 command on an MVS console or SDSF to start the Network SLAPM2 subagent. A sample procedure is included in member EZAPAGSB in SEZAINST.

- Specify LIBPATH using the ENVAR parameter on the PARM statement in the started procedure. For example:

```
// PARM=('POSIX(ON) ALL31(ON)',
// 'ENVAR("LIBPATH=/usr/lib")/')
```

- Export the LIBPATH environment variable in a file specified with the STDENV DD statement. For example:

```
//STDENV DD PATH='/etc/nslapm2.env',PATHOPTS=(ORDONLY)
```

In the /etc/nslapm2.env file:

```
LIBPATH=/usr/lib
```

For more information about specifying runtime options and environment variables, see [z/OS Language Environment Programming Guide](#). For details about setting the LIBPATH environment variable, also see [z/OS UNIX System Services Command Reference](#).

Following is a copy of the sample procedure:

```
//NSLAPM2 PROC
//*
//* z/OS Communications Server IP
//* SMP/E distribution name: EZAPAGSB
//*
//* 5650-ZOS Copyright IBM Corp. 2006, 2013
//* Licensed Materials - Property of IBM
//*
//NSLAPM2 EXEC PGM=NSLAPM2,REGION=0K,TIME=NOLIMIT,
//      PARM='ENVAR("_CEE_ENVFILE_S=DD:STDENV")/'
//*
//* Example of passing parameters to the program (parameters must
//* extend to column 71 and be continued in column 16):
//*      PARM='ENVAR("_CEE_ENVFILE_S=DD:STDENV")/-c public -P 1234 -p TCP
//*      IP'
//*
//* Provide environment variables to run with the desired stack. As
//* an example, the data set or file specified by STDENV could
//* contain:
//*
//*      RESOLVER_CONFIG=//SYS1.TCPPARMS(TCPDATA)'
//*      LIBPATH=/usr/lib
//*
//* If you want to include comments in the data set or
//* z/OS UNIX file, specify the _CEE_ENVFILE_COMMENT
//* environment variable as the first environment variable
//* in the data set or file. The value specified for
//* the _CEE_ENVFILE_COMMENT variable is the comment character.
//* For example, if you want to use the pound sign, #, as
//* the comment character, specify this as the first
//* statement:
//*      _CEE_ENVFILE_COMMENT=#
//*
//* For information on the above environment variable, refer to the
//* IP Configuration Guide. Other environment variables can also be
//* specified via STDENV.
//*
//STDENV DD DUMMY
//* Sample MVS data set containing environment variables:
//*STDENV DD DSN=TCPIP.NSLAPM2.ENV(NSLAPM2),DISP=SHR
//* Sample HFS file containing environment variables:
//*STDENV DD PATH='/etc/nslapm2.env',PATHOPTS=(ORDONLY)
//*
//* Output written to stdout and stderr goes to the data set or
//* file specified with SYSPRINT or SYSOUT, respectively. But
//* normally, NSLAPM2 doesn't write output to stdout or stderr.
//* Instead, output is written to syslogd. When the -o parameter
//* is specified, however, output is written to stdout instead of
//* syslogd.
//*
//SYSPRINT DD SYSOUT=*
//SYSOUT DD SYSOUT=*
//*
//CEEDUMP DD SYSOUT=*,DCB=(RECFM=FB,LRECL=132,BLKSIZE=132)
```

Figure 29. NSLAPM2 sample procedure

Restriction: When you use the environment variable _CEE_ENVFILE with an MVS data set, allocate the data set with the value RECFM=V. You should not use RECFM=F because RECFM=F causes the environment variable values to be padded with blanks.

Network SLAPM2 subagent environment variables

Table 87 on page 1145 provides a list of environment variables used by Network SLAPM2 subagent that can be tailored to a particular installation:

Table 87. Network SLAPM2 subagent environment variables			
Environment variable	Server, Client or Command-type application	Description	Any specific coding rules (or a link to syntax)
SNMP_PORT	nslapm2	Specifies the port to which a DPI subagent directs a connection query. The default is 161 (the default port on which the SNMP agent listens for queries).	None

Starting the traffic regulation manager daemon (TRMD) from the z/OS shell

TRMD is used with intrusion detection services (IDS), IP Security, and ZERT to write event messages and statistics to the syslog daemon (syslogd).

The offset from Coordinated Universal Time (UTC) of the syslog time in the timestamp of TRMD messages is determined by the TZ environment variable described in [z/OS UNIX System Services User's Guide](#).

To cause the timestamp to appear in Coordinated Universal Time (UTC), change the TZ specification in /etc/profile or export TZ="0" before starting TRMD.

The -p start option or the resolver configuration file is used to determine the stack that TRMD uses.

Syntax

```
➔ trmd -dn -pstackname ➔
```

Parameters

-d n

Specifies that the TRMD should run in debugging mode. The following modes are supported:

- 1 Internal debugging messages are written.
- 2 Internal and API debugging messages are written.
- 3 Internal debugging messages and output from the ioctl's issued to the stack are written.

-p stackname

Specifies the TCP/IP stack name that TRMD uses. If this parameter is not specified, TRMD uses the resolver configuration file to determine the stack name.

Output is written to syslogd.

Starting the traffic regulation manager daemon (TRMD) as a started task

The offset from Coordinated Universal Time (UTC) of the syslog time in the timestamp of TRMD messages is determined by the TZ environment variable described in [z/OS UNIX System Services User's Guide](#).

To cause the timestamp to appear in coordinated universal time (UTC), specify the TZ environment variable in the start TRMD procedure. For example:

```
// PARM=('POSIX(ON) ALL31(ON) ',
// 'ENVAR("LIBPATH=/usr/lib"',
// '"TZ=0")/-d 1')
```

Use the S TRMD command on an MVS console or SDSF to start the TRM daemon. A sample procedure is included in member EZATRMD in SEZAINST.

```
//TRMD      PROC
//*
//*  IBM Communications Server for z/OS
//*  SMP/E distribution name: EZATRMDP
//*
//*  5650-ZOS Copyright IBM Corp. 1996, 2013
//*  Licensed Materials - Property of IBM
//*  "Restricted Materials of IBM"
//*
//*  Status = CSV2R1
//*
//*  Function: Sample procedure for running the Traffic
//*            Regulator Management Daemon (TRMD)
//*
//TRMD      EXEC PGM=EZATRMD,REGION=4096K,TIME=NOLIMIT,
//          PARM=('POSIX(ON) ALL31(ON) ',
//          'ENVAR("LIBPATH=/usr/lib")/')
//*
//*** Notes:
//*
//* - TRMD can also be invoked from the Unix System Services shell
//*   as a shell command: trmd
//*
//* - The system link list concatenation must contain the TCP/IP
//*   runtime libraries and the C runtime libraries. If they are
//*   not in the link list concatenation, this procedure will need
//*   to be changed to STEPLIB to them.
//*
//* - To pass parameters to TRMD, specify them after the final slash
//*   on the PARM statement. For example:
//*       // PARM=('POSIX(ON) ALL31(ON)/-d 1')
//*
//* - TRMD must find the TCP/IP job name with which it should be
//*   associated. It uses the -p start option or the TCPIPJOBNAME value
//*   from the TCPIP.DATA file. The TCPIP.DATA file used can be
//*   controlled by setting the RESOLVER_CONFIG environment variable.
//*   See examples below.
//*
//*** Examples for specifying environment variables and parameters
//*** (parameters must extend to column 71 and be continued in
//*** column 16):
//*
//* Example 1: Environment variables inline, MVS resolver data set
//*
//* PARM=('POSIX(ON) ALL31(ON) ',
//* 'ENVAR("RESOLVER_CONFIG=//'"SYS1.TCPPARMS(TCPDATA)'"', "TZ=EST5EDT
//*        ")/')
//*
//* Example 2: Environment variables inline, UNIX resolver file
//*
//* PARM=('POSIX(ON) ALL31(ON) ',
//* 'ENVAR("RESOLVER_CONFIG=/etc/resolv.conf", "TZ=EST5EDT")/')
//*
//* Example 3: Environment variables in STDENV DD
//*
//* PARM=('POSIX(ON) ALL31(ON) ',
//* 'ENVAR("_CEE_ENVFILE_S=DD:STDENV")/')
//*
//* For this method, the STDENV DD statement below must be
```

```

/** changed to point to a MVS data set or UNIX file containing
/** settings for any environment variables. For example, it should
/** contain at least TZ (unless you choose to specify TZ in a
/** different fashion), but can contain other environment variables
/** as in this example:
/**
/**     RESOLVER_CONFIG=/'SYS1.TCPPARMS(TCPDATA)'
/**     TZ=EST5EDT
/**
/** If you want to include comments in the data set or
/** z/OS UNIX file, specify the _CEE_ENVFILE_COMMENT
/** environment variable as the first environment variable
/** in the data set or file. The value specified for
/** the _CEE_ENVFILE_COMMENT variable is the comment character.
/** For example, if you want to use the pound sign, #, as
/** the comment character, specify this as the first
/** statement:
/**     _CEE_ENVFILE_COMMENT=#
/**
/** The use of the STDENV DD statement works well when more than
/** one environment variable is specified, as there is a JCL limit
/** of 100 characters on the PARM statement.
/**
/** Note: Language Environment recommends a variable record format
/** for the STDENV file.
/**
/** You can also set the TZ environment variable for all applications
/** in the CEEPRMxx PARMLIB member. You should define the TZ
/** environment variable for all three LE option sets (CEEDOPT,
/** CEECOPT, and CELQDOPT). For example:
/**
/**     CEECOPT(ALL31(ON), ENVAR('TZ=EST5EDT')) )
/**     CEEDOPT(ALL31(ON), ENVAR('TZ=EST5EDT')) )
/**     CELQDOPT(ALL31(ON), ENVAR('TZ=EST5EDT')) )
/**
/** For more information on specifying run-time options, see z/OS
/** Language Environment Programming Guide. For details on setting
/** the LIBPATH and TZ environment variables, see z/OS UNIX System
/** Services Command Reference.
/**
/**STDENV DD DUMMY
/** Sample MVS data set containing environment variables:
/**STDENV DD DSN=TCPIP.TRMD.ENV(TRMD),DISP=SHR
/** Sample UNIX file containing environment variables:
/**STDENV DD PATH='/etc/trmd.env',PATHOPTS=(ORDONLY)
/**SYSPRINT DD SYSOUT=*,DCB=(RECFM=F,LRECL=80,BLKSIZE=80)
/**SYSIN DD DUMMY
/**SYSERR DD SYSOUT=*
/**SYSOUT DD SYSOUT=*,DCB=(RECFM=F,LRECL=80,BLKSIZE=80)
/**CEEDUMP DD SYSOUT=*,DCB=(RECFM=FB,LRECL=132,BLKSIZE=132)

```

Figure 30. TRMD sample procedure

Chapter 17. RSVP Agent

Restriction: IPv6 support is not provided for RSVP agent at this time.

For related information about RSVP Agent, see the policy based networking information in [z/OS Communications Server: IP Configuration Guide](#).

RSVP Agent configuration file

The RSVP Agent uses the following search order to locate the configuration file (highest priority is listed first):

- z/OS UNIX file or MVS data set specified by the -c startup option. The syntax for a z/OS UNIX file is '/dir/file' and the syntax for an MVS data set is "'MVS.DATASET.NAME'".
- z/OS UNIX file or MVS data set specified with the RSVPD_CONFIG_FILE environment variable.
- /etc/rsvpd.conf z/OS UNIX file.
- 'hlq.RSVPD.CONF' MVS data set.

Restriction: If this file is not present, RSVP is enabled on all network interfaces with default parameters.

LogLevel statement

Use the LogLevel statement to specify the level of tracing.

Syntax

➤ LogLevel — *i* ➤

Parameters

i

An integer that specifies the level of logging/tracing. The supported levels are:

- 1 - SYSERR - System error messages
- 2 - OBJERR - Object error messages
- 4 - PROTERR - Protocol error messages
- 8 - WARNING - Warning messages
- 16 - EVENT - Event messages
- 32 - ACTION - Action messages
- 64 - INFO - Informational messages
- 128 - ACNTING - Accounting messages
- 256 - TRACE - Trace messages

Usage notes

Specify a desired log level or a combination of levels. If this statement is absent, the default level is 15.

To combine log levels, add log level numbers. For example, to request SYSERR messages (level 1) and EVENT messages (level 16), you would request log level 17.

Examples

The following example turns on all trace levels for RSVP.

```
LogLevel 511
```

TcpImage statement

Use the TcpImage statement to identify the name of the stack to which the RSVP agent should establish affinity.

Rule: If the TcpImage statement is absent, the RSVP agent establishes affinity with the default stack.

Syntax

►► TcpImage — *name* ◄◄

Parameters

name

The name of the TCP/IP image. The name must be one to eight characters.

Examples

```
TcpImage TCPCS2
```

Interface statement

Use the Interface statement to make available to the RSVP agent one or more of the network interfaces of the local host.

Rule: If the Interface statement is absent, none of the network interfaces are available to the RSVP agent.

Syntax

Note 1: Place braces and parameters on separate lines

Interface Parameters

Parameters

IP_address

The IP address (dotted decimal format) of the interface. You can choose a specific interface IP address such as *all*, which means all configured interfaces (currently configured on the HOME statement or dynamically added in the future), or *others*, which means all interfaces except those previously configured.

In the following example, all interfaces except 9.10.11.12 would be enabled.

```
Interface 9.10.11.12 Disabled
Interface others Enabled
```

Enabled

Specifies that RSVP should use this interface.

Disabled

Specifies that RSVP should not use this interface.

Off

Specifies to ignore this statement.

TrafficControl

Specifies whether or not traffic control is in effect. When traffic control is disabled, the RSVP agent does not install any filters (resource reservations). If *off* is specified, the traffic control specification portion of the Interface statement is ignored.

Examples

```
Interface 9.23.78.13
{
  trafficcontrol enabled
}
```

```
interface others disabled
```

```
interface all
```

RSVP statement

Use the RSVP statement to enable RSVP processing on one or more of the network interfaces of the local host.

Rule: If this statement is absent, RSVP processing is disabled on all network interfaces.

Syntax

Put Braces and Parameters on Separate Lines

RSVP Parameters

Parameters

IP_address

The IP address (dotted decimal format) of the interface. You can choose a specific interface IP address such as *all*, which means all configured interfaces (currently configured on the HOME statement or dynamically added in the future), or *others* which means all interfaces except those previously configured.

In the following example, all interfaces except 9.10.11.12 would be enabled.

```
Interface 9.10.11.12 Disabled
Interface others Enabled
```

Enabled

Specifies that RSVP processing should use this interface.

Disabled

Specifies that RSVP processing should not use this interface.

Off

Specifies to ignore this statement.

MaxFlows

Specifies the maximum number of data flows.

i

An integer defining the maximum number of data flows to be allowed using this interface. The default is 32.

Examples

```
rsvp 87.13.112.6
```

```
{
maxflows 100
}
```

```
rsvp others
```

```
rsvp all
```

RSVPD.CONF search order

The search order for accessing RSVPD.CONF information is as follows. The first file found in the search order is used.

1. z/OS UNIX file or MVS data set specified by the -c startup option. The syntax for a z/OS UNIX file is '/dir/file' and the syntax for an MVS data set is "'MVS.DATASET.NAME'".
2. z/OS UNIX file or MVS data set specified with the RSVPD_CONFIG_FILE environment variable.
3. /etc/rsvpd.conf z/OS UNIX file.
4. 'hlq.RSVPD.CONF' MVS data set.

Restriction: If this file is not present, RSVP is enabled on all network interfaces with default parameters.

Starting RSVP from the z/OS shell

The rsvp executable program resides in /usr/lpp/tcpip/sbin. There is also a link from /usr/sbin.

Requirement: Make sure your path statement (in the profile) contains either /usr/sbin or /usr/lpp/tcpip/sbin.

➤ rsvpd ————— ➤
 └─ -c — filename ─┘

-c

The -c option allows an RSVP Agent configuration file to be specified. If it is not specified, the configuration file is located using the search order.

Starting RSVP as a started task

Use the S RSVPD command on an MVS console or SDSF to start RSVP. A sample procedure is shipped in member EZARSVPP in SEZAINST. All of the information regarding default locations for the configuration and log files is the same as for starting from the z/OS shell. Following is a copy of the sample procedure:

```

//RSVPD    PROC
//*
//* SecureWay Communications Server IP
//* SMP/E distribution name: EZARSVPP
//*
//* 5650-ZOS (C) Copyright IBM Corp. 1999, 2013
//* Licensed Materials - Property of IBM
//*
//RSVPD    EXEC PGM=RSVPD,REGION=0K,TIME=NOLIMIT,
//          PARM='POSIX(ON) ALL31(ON) ENVAR("_CEE_ENVFILE_S=DD:STDENV")/'
//*
//* Example of passing parameters to the program (parameters must
//* extend to column 71 and be continued in column 16):
//*          PARM='POSIX(ON) ALL31(ON) ENVAR("_CEE_ENVFILE_S=DD:STDENV")/-c /
//*          etc/rsvpd25.conf'
//*
//* Provide environment variables to run with the desired stack and
//* configuration. As an example, the data set or file specified by
//* STDENV could contain:
//*
//*          RESOLVER_CONFIG=// 'SYS1.TCPPARMS(TCPDATA2)'
//*          RSVPD_CONFIG_FILE=/etc/rsvpd2.conf
//*          RSVPD_LOG_FILE=/tmp/rsvpd2.log
//*
//* If you want to include comments in the data set or
//* z/OS UNIX file, specify the _CEE_ENVFILE_COMMENT
//* environment variable as the first environment variable
//* in the data set or file. The value specified for
//* the _CEE_ENVFILE_COMMENT variable is the comment character.
//* For example, if you want to use the pound sign, #, as
//* the comment character, specify this as the first
//* statement:
//*          _CEE_ENVFILE_COMMENT=#
//*
//* For information on the above environment variables, refer to the
//* IP CONFIGURATION GUIDE. Other environment variables can also be
//* specified via STDENV.
//*
//STDENV   DD DUMMY
//* Sample MVS data set containing environment variables:
//*STDENV   DD DSN=TCPIP.RSVPD.ENV(RSVPD2),DISP=SHR
//* Sample HFS file containing environment variables:
//*STDENV   DD PATH='/etc/rsvpd2.env',PATHOPTS=(ORDONLY)
//*
//* Output written to stdout and stderr goes to the data set or
//* file specified with SYSPRINT or SYSOUT, respectively. But
//* normally, RSVPD doesn't write output to stdout or stderr.
//* Instead, output is written to the log file, which is specified
//* by the RSVPD_LOG_FILE environment variable, and defaults to
//* /tmp/rsvpd.log.
//*
//SYSPRINT DD SYSOUT=*
//SYSOUT   DD SYSOUT=*
//*
//CEEDUMP  DD SYSOUT=*,DCB=(RECFM=FB,LRECL=132,BLKSIZE=132)

```

Figure 31. RSVP sample procedure

Restriction: When you use the environment variable `_CEE_ENVFILE` with an MVS data set, allocate the data set with the value `RECFM=V`. To use a `RECFM=F` data set, `_CEE_ENVFILE_S` should be used to prevent the environment variable values from being padded with blanks.

Chapter 18. Intrusion detection services policy

This topic contains the following information about the intrusion detection services (IDS) policy:

- [“IDS policies defined in IDS configuration files” on page 1155](#)
- [“IDS Policies defined in LDAP” on page 1155](#)

IDS policies defined in IDS configuration files

For information about configuring the intrusion detection services (IDS) rules and actions in the IDS configuration files, see [Chapter 16, “Policy Agent and policy applications,” on page 819](#).

If you are migrating your IDS policy from Lightweight Directory Access Protocol (LDAP) to IDS configuration files, be aware that the IDS configuration file policy rule and action parameters are consistent with the IDS LDAP policy rule and action parameters, except for the following parameters:

- IDSAttackCondition
 - IfcFloodPercentage
 - IfcFloodMinDiscard
- IDSScanEventCondition
 - Sensitivity
 - IDSScanExclusion
 - IDSScanExclusionRef
- IDSScanGlobalCondition
 - FSInterval
 - FSThreshold
 - SSInterval
 - SSThreshold
- IDSTRCondition
 - TRtcpTotalConnections
 - TRudpQueueSize
 - TRtcpPercentage
 - TRtcpLimitScope

IDS Policies defined in LDAP

This topic lists the LDAP object classes and attributes used to define IDS policy objects. The default and allowable values for IDS-specific attributes are included, as well as information showing the allowable combinations of attributes in various types of IDS policies. See [Appendix B, “LDAP definition files,” on page 1319](#) for more information about object classes and their attributes. See [z/OS Communications Server: IP Configuration Guide](#) for additional guidance about defining IDS policies.

Restriction: Not all IDS policy options are available in Lightweight Directory Access Protocol (LDAP) configuration file. You cannot use LDAP to do the following tasks:

- Specify that ICMPv6 traffic should be monitored for scan events
- Exclude IPv6 addresses from the scan exclusion list
- Define rules for the following attack types:
 - DATA_HIDING

- EE_LDLC_CHECK
- EE_MALFORMED_PACKET
- EE_PORT_CHECK
- EE_XID_FLOOD
- GLOBAL_TCP_STALL
- OUTBOUND_RAW_IPV6
- RESTRICTED_IPV6_DST_OPTIONS
- RESTRICTED_IPV6_HOP_OPTIONS
- RESTRICTED_IPV6_NEXT_HDR
- TCP_QUEUE_SIZE
- Define TCP traffic regulation policy that specifies IPv6 addresses
- Define UDP traffic regulation policy that specifies IPv6 addresses

The following Object classes are useful in building an LDAP tree structure of policy groups of rules and policy repositories of reusable conditions and actions.

- objectclass ibm-policy
- objectclass ibm-policyGroup
- objectclass ibm-policyRepository
- objectclass ibm-policyGroupContainmentAuxClass
- objectclass ibm-policyRuleContainmentAuxClass

The following Object classes are useful in building IDS rule, condition association, rule-specific condition, reusable condition, action association, rule-specific action and reusable action objects.

- objectclass ibm-policyRule
- objectclass ibm-policyRuleConditionAssociation
- objectclass ibm-policyRuleActionAssociation
- objectclass ibm-policyInstance
- objectclass ibm-policyConditionInstance
- objectclass ibm-policyActionInstance
- objectclass ibm-policyConditionAuxClass
- objectclass ibm-policyActionAuxClass
- objectclass ibm-policyTimePeriodConditionAuxClass

The following Object classes are required for IDS-specific condition objects. These classes are not permitted in QoS specific policies.

- objectclass ibm-idsConditionAuxClass
- objectclass ibm-idsAttackConditionAuxClass
- objectclass ibm-idsIPAttackConditionAuxClass
- objectclass ibm-idsFloodAttackActionsAuxClass
- objectclass ibm-idsTrafficRegulationConditionAuxClass
- objectclass ibm-idsScanConditionAuxClass
- objectclass ibm-idsScanEventConditionAuxClass
- objectclass ibm-idsTransportConditionAuxClass
- objectclass ibm-idsHostConditionAuxClass

The following Object classes are required for IDS-specific action objects. These classes are not permitted in QoS specific policies.

- objectclass ibm-idsActionAuxClass
- objectclass ibm-idsNotificationAuxClass
- objectclass ibm-idsAttackActionsAuxClass
- objectclass ibm-idsTrafficRegulationActionAuxClass
- objectclass ibm-idsTRtcpActionAuxClass
- objectclass ibm-idsTRudpActionAuxClass
- objectclass ibm-idsScanActionAuxClass
- objectclass ibm-idsScanSensitivityActionAuxClass
- objectclass ibm-idsScanExclusionActionAuxClass

The following Object classes are not permitted in IDS specific objects either because they are only valid for Version 2 policies or because they are only permitted in QoS specific objects.

- objectclass ibm-policyCondition
- objectclass ibm-policyTimePeriodCondition
- objectclass ibm-networkingPolicyCondition
- objectclass ibm-policyAction
- objectclass ibm-serviceCategories
- objectclass ibm-networkingPolicyConditionAuxClass
- objectclass ibm-routeConditionAuxClass
- objectclass ibm-hostConditionAuxClass
- objectclass ibm-applicationConditionAuxClass
- objectclass ibm-serviceCategoriesAuxClass
- objectclass ibm-policyGroupLoadDistributionAuxClass
- objectclass SetSubnetPrioTosMask

IDS-specific condition attributes, their object class, as well as allowed and default values are listed in [Table 88 on page 1157](#).

<i>Table 88. IDS-specific condition attributes</i>		
Attribute	Class	Allowed and default values
ibm-idsConditionType	ibm-idsConditionAuxClass	<ul style="list-style-type: none"> • ATTACK • TR • SCAN_GLOBAL • SCAN_EVENT No default

Table 88. IDS-specific condition attributes (continued)

Attribute	Class	Allowed and default values
ibm-idsAttackType	ibm-idsAttackConditionAuxClass	<ul style="list-style-type: none"> • MALFORMED_PACKET • FLOOD • OUTBOUND_RAW • PERPETUAL_ECHO • IP_FRAGMENT • RESTRICTED_IP_OPTIONS • RESTRICTED_IP_PROTOCOL • ICMP_REDIRECT No default
ibm-idsIPOptionRange	ibm-idsIPAttackConditionAuxClass	1 - 255 Default is 0 (all)
ibm-idsLocalPortRange	ibm-idsTransportConditionAuxClass	0–65535 Default is 0 (all)
ibm-idsRemotePortRange	ibm-idsTransportConditionAuxClass	0 - 65535 Default is 0 (all)
ibm-idsProtocolRange	ibm-idsTransportConditionAuxClass	0 - 255 Default is Protocol 0
ibm-idsLocalHostIPAddress	ibm-idsHostConditionAuxClass	Any valid IP address Default is 0 (all)
ibm-idsRemoteHostIPAddress	ibm-idsHostConditionAuxClass	Any valid IP address Default is 0 (all)

IDS-specific action attributes, their object class, and allowed and default values are shown in [Table 89](#) on [page 1158](#).

Table 89. IDS-specific action attributes

Attribute	Class	Allowed values
ibm-idsIfcFloodPercentage	ibm-idsFloodAttackActionsAuxClass	5 - 100 Default is 10.

Table 89. IDS-specific action attributes (continued)

Attribute	Class	Allowed values
ibm-idsIfcFloodMinDiscard	ibm-idsFloodAttackActionsAuxClass	100 - 4 294 967 295 Minimum number of discards that must occur in a one minute interval for an interface flood condition to exist. Default is 1 000.
ibm-idsActionType	ibm-idsActionAuxClass	<ul style="list-style-type: none"> • ATTACK • TR • SCAN_GLOBAL • SCAN_EVENT No default
ibm-idsNotification	ibm-idsNotificationAuxClass	<ul style="list-style-type: none"> • NONE • SYSLOG • SYSLOGDETAIL • CONSOLE No default
ibm-idsStatInterval	ibm-idsNotificationAuxClass	0 - 4 294 967 295 Default is 60
ibm-idsLoggingLevel	ibm-idsNotificationAuxClass	0 - 7 These values map to syslogd priority levels as follows: 0 Emerg/panic 1 Alert 2 Crit 3 Error 4 Warning 5 Notice 6 Info 7 Debug Default is 0

Table 89. IDS-specific action attributes (continued)

Attribute	Class	Allowed values
ibm-idsTypeActions	ibm-idsNotificationAuxClass	<ul style="list-style-type: none"> • STATISTICS • EXCEPTSTATS • LOG • LIMIT No default
ibm-idsTraceData	ibm-idsNotificationAuxClass	<ul style="list-style-type: none"> • NONE • HEADER • FULL • RECORDSIZE Default is HEADER
ibm-idsTraceRecordSize	ibm-idsNotificationAuxClass	0 - 4 294 967 295 Default is 100
ibm-idsMaxEventMessage	ibm-idsAttackActionsAuxClass	0 - 4 294 967 295 Default is 0
ibm-idsTRtcpTotalConnections	ibm-idsTRtcpActionAuxClass	0 - 65 535 Default is 65535
ibm-idsTRtcpPercentage	ibm-idsTRtcpActionAuxClass	0 - 100 Default is 100
ibm-idsTRtcpLimitScope	ibm-idsTRtcpActionAuxClass	<ul style="list-style-type: none"> • PORT • PORT_INSTANCE Default is PORT_INSTANCE
ibm-idsTRudpQueueSize	ibm-idsTRudpActionAuxClass	<ul style="list-style-type: none"> • VERY_LONG • LONG • SHORT • VERY_SHORT Default is VERY_LONG
ibm-idsFSInterval	ibm-idsScanActionAuxClass	1 - 1440 Default is 1
ibm-idsFSThreshold	ibm-idsScanActionAuxClass	1 - 64 Default is 5
ibm-idsSSInterval	ibm-idsScanActionAuxClass	0 - 1 440 Default is 120
ibm-idsSSThreshold	ibm-idsScanActionAuxClass	0 - 64 Default is 10

Table 89. IDS-specific action attributes (continued)		
Attribute	Class	Allowed values
ibm-idsSensitivity	ibm-idsScanSensitivityActionAuxClass	<ul style="list-style-type: none"> • NONE • HIGH • MEDIUM • LOW No default
ibm-idsScanExclusion	ibm-idsScanExclusionActionAuxClass	Any valid IP address, 0 - 65 535 for ports Default is 0 (none)

The tables in this topic list the combinations of attributes that are used for different types of IDS policy. Mapping conditions are the attributes used by the code when searching for rules.

Use the following guidelines for interpreting the following tables:

- Quoted strings are literal attribute values.
- X indicates *not* supported; the containing policy is not mapped.
- I indicates ignored.
- A indicates allowed.
- R indicates required.

Table 90 on page 1161 lists the IDS scan global policies.

Chapter 19. Simple Network Management Protocol

This topic provides information about configuring and starting the following SNMP functions:

- “SNMP agent (OSNMPD)” on page 1173
- “SNMP query engine (SNMPQE)” on page 1205
- “z/OS UNIX snmp command” on page 1209
- “TRAPFWD daemon” on page 1214

SNMP agent (OSNMPD)

This topic includes information about the SNMP agent (OSNMPD).

Starting OSNMPD from MVS

If you want to start the SNMP agent by using an MVS cataloged procedure, you can use the sample cataloged procedure, OSNMPDPR. Copy member OSNMPDPR from SEZAINST to your system or recognized PROCLIB. The default name for the SNMP agent is OSNMPD. Specify the SNMP agent parameters that you need and change the data set or file names to suit your local configuration.

Sample SNMP agent cataloged procedure

Following is the sample SNMP agent cataloged procedure, OSNMPDPR. See the comments after the JCL EXEC statement for examples of how to specify configuration files, environment variables, and parameters to the SNMP agent.

```
//OSNMPD    PROC
//*
//* Sample procedure for running the z/OS UNIX SNMP agent
//*
//* z/OS Communications Server Version 2 Release 1
//* SMP/E Distribution Name: SEZAINST(EZASNDPR)
//*
//*
//* Copyright:    Licensed Materials - Property of IBM
//*              5650-ZOS
//*              Copyright IBM Corp. 1997, 2013
//*
//* Status:      CSV2R1
//*
//OSNMPD EXEC PGM=EZASNDPR,REGION=4096K,TIME=NOLIMIT,
//  PARM='-d 0'
//*
//*** Notes:
//*
//* - The C runtime libraries should be in the system's link list
//*   or this sample procedure will need to STEPLIB to them.
//*
//* - TCP/IP runtime libraries should also be in the system's link
//*   list.
//*
//* - OSNMPD must find the name (TCPIPJOBNAME in TCPIP.DATA) that
//*   it should be associated with. The OE function __iptcpn() is
//*   used to find this name. It is suggested that the parmlist
//*   be modified to set the environment variable
//*   RESOLVER_CONFIG to point to the correct resolver file when
//*   multiple INET Physical File Systems are started. See the
//*   examples below.
//*
//*   If only one INET PFS will be started then /etc/resolv.conf
//*   may be used.
//*
//* - The OSNMPD agent can also be invoked from the OMVS shell as
//*   a shell command.
//*
```

```

//*** Examples for specifying configuration data sets
//*
//* Example 1: TCPIP.DATA in partitioned data set on the
//* RESOLVER_CONFIG environment variable
//*
//* // PARM=(,
//* // 'ENVAR("RESOLVER_CONFIG=/'TCPA.MYFILE(TCPDATA)')')/-d 0')
//*
//* Example 2: TCPIP.DATA on a SYSTCPD DD statement
//*
//* As an alternative to setting the RESOLVER_CONFIG environment
//* variable, the SYSTCPD DD card may be specified.
//* SYSTCPD explicitly identifies which data set is to be
//* used to obtain the parameters defined by TCPIP.DATA
//* when no GLOBALTCPIPDATA statement is configured.
//* See the IP Configuration Guide for information on
//* the TCPIP.DATA search order.
//* The data set can be any sequential data set or a member of
//* a partitioned data set (PDS).
//*
//* //SYSTCPD DD DSN=TCPIP.SEZAINST(TCPDATA),DISP=SHR
//*
//* Example 3: TCPIP.DATA and SNMPD.CONF in HFS files
//*
//* // PARM=('ENVAR("RESOLVER_CONFIG=/etc/tcpa.data"',
//* // '"SNMPD_CONF=/etc/snmpd.conf.tcpa")',
//* // '/-d 0')
//*
//* Example 4: Specification of data sets via STDENV DD statement
//*
//* // PARM=('ENVAR("_CEE_ENVFILE_S=DD:STDENV")/-d 0')
//*
//* For this method, the STDENV DD statement below must be
//* uncommented and set to point to a data set containing
//* settings for any environment variables. For example, it
//* can contain
//*
//* RESOLVER_CONFIG=/'TCPIVP.TCPPARMS(TCPDATA)'
//* SNMPD_CONF=/'TCPIVP.TCPPARMS(SNMPDIVP)'
//*
//* If you want to include comments in the data set or
//* z/OS UNIX file, specify the _CEE_ENVFILE_COMMENT
//* environment variable as the first environment variable
//* in the data set or file. The value specified for
//* the _CEE_ENVFILE_COMMENT variable is the comment character.
//* For example, if you want to use the pound sign, #, as
//* the comment character, specify this as the first
//* statement:
//* _CEE_ENVFILE_COMMENT=#
//*
//* The use of the STDENV DD statement works well when more than
//* one environment variable is specified, as there is a JCL limit
//* of 100 characters on the PARM= statement.
//*
//*** Example for specifying z/OS UNIX pathname
//*
//* If you have configured a common INET (CINET) environment, and
//* you want to start an SNMP agent for more than one TCP/IP stack,
//* and you are going to enable SNMP subagents that connect to
//* the agent using a z/OS UNIX connection, you will need to
//* define unique z/OS UNIX pathnames for each agent. You do
//* this by specifying the -s parameter:
//*
//* // PARM='-d 0 -s /var/tcpip1_dpi_socket'
//*
//*** See the SNMP chapters in the IP Configuration Guide and the
//* IP Configuration Reference for details on the configuration
//* files used by the SNMP agent, the search orders associated
//* with them, and the SNMP agent start parameters.
//*
//*
//*
//*SYSTCPD DD DSN=TCPIP.SEZAINST(TCPDATA),DISP=SHR
//*STDENV DD DSN=TCPIVP.TCPPARMS(SNMPENV),DISP=SHR
//*SYSPRINT DD SYSOUT=*,DCB=(RECFM=F,LRECL=80,BLKSIZE=80)
//*SYSIN DD DUMMY
//*SYSERR DD SYSOUT=*
//*SYSOUT DD SYSOUT=*,DCB=(RECFM=F,LRECL=80,BLKSIZE=80)
//*CEEDUMP DD SYSOUT=*

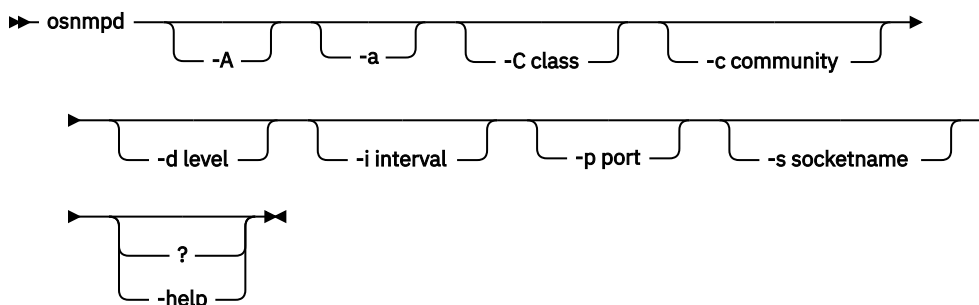

```

Figure 32. OSNMPD MVS started procedure

Restriction: When you use the environment variable `_CEE_ENVFILE` with an MVS data set, allocate the data set with the value `RECFM=V`. You should not use `RECFM=F` because `RECFM=F` causes the environment variable values to be padded with blanks.

Starting OSNMPD from the z/OS UNIX System Services shell

To start OSNMPD from the z/OS UNIX System Services shell, use the following syntax:

OSNMPD parameters

The SNMP agent (OSNMPD) runs in a separate address space that executes load module EZASNMPD. OSNMPD can be started without parameters or you can add any of the parameters in this topic.

When starting OSNMPD from MVS, add the parameters to the `PARMS=` keyword on the `EXEC` statement of the OSNMPD cataloged procedure. When starting OSNMPD from z/OS UNIX System Services, specify the desired parameters on the `osnmpd` command.

Rule: The parameters must be entered in lowercase because they are case sensitive.

Parameter Description

-A

Forces the SNMP Agent to obtain an IPv4 address for itself when it initializes. If no IPv4 addresses are available, then the IPv4 loopback address (127.0.0.1) is used. If this parameter is not specified, the SNMP Agent uses an IP address that might be IPv6 or IPv4.

-a

Specifies that the packets sent by the SNMP Agent for responses and notifications should be sent using the physical interface address, rather than a VIPA address (if `SOURCEVIPA` is configured).

-C class

Permits you to control SNMP subagent connections to the SNMP agent via a z/OS UNIX connection. For z/OS UNIX connections, a z/OS UNIX path name is used. This path name can be specified on the agent's `-s` parameter. See the description of the `-s` parameter in this topic for more information. All of the z/OS Communications Server SNMP subagents use a z/OS UNIX connection to connect to the agent.

In order for subagents to successfully connect to the agent, either the subagents must be defined with superuser authority or the path name's read and write file access permission bits must be set for the class associated with the subagent's user ID. For more detailed information about file access permission bits, see the information about handling security for your files in [z/OS UNIX System Services User's Guide](#).

This parameter's *class* value specifies the class or classes of the subagent user IDs, for those subagents that you want to permit to connect to the SNMP agent using a z/OS UNIX connection. This parameter causes the path name's read and write file access permission bits to be set for the specified classes.

The valid values for the *class* variable are 1 - 4 and are defined as follows:

1 Group class

Specify this value if you want only those subagents whose user IDs are associated with the same security product group as the agent to be able to connect. The resulting file access permission bit value in octal is 660.

2 Other class

Specify this value if you want only those subagents whose user IDs are not associated with the same security product group as the agent to be able to connect. The resulting file access permission bit value in octal is 606.

3 Both Group and Other class

Specify this value if you want all subagents to be able to connect to the agent. The resulting file access permission bit value in octal is 666.

4 Only User class

Specify this value if you do not want any subagents to be able to connect to the agent using a z/OS UNIX connection.

If the `-C` parameter is not specified, default level 1 is used. This means that the group read and write permission bits for the path name are set and that subagents whose user IDs are associated with the same security product group as the SNMP agent are able to connect.

-c community

This parameter can be used to dynamically configure a community name to the agent instead of defining it in the SNMP agent configuration file. A community name is a password that can accompany an SNMP request that the agent receives. Use community names with community-based security to restrict access to SNMP management data. See [Configure the SNMP agent](#) and [Step 1: Configure the SNMP agent \(OSNMPD\)](#) in [z/OS Communications Server: IP Configuration Guide](#) for more information about community-based security.

Restriction: This parameter should only be specified when the community names are defined in a PW.SRC file. Authentication errors can occur if this parameter is specified and the community names are defined in a SNMPD.CONF configuration file.

The value that you specify for *community* is configured as both an ASCII and an EBCDIC community name. This parameter should be specified only if you are using community-based security with the SNMP agent, and you want to dynamically define a community name that any requestor can use to retrieve SNMP management data. Specifying a community name on this parameter when starting the agent causes the community to be defined to the agent with a mask and an IP address of zeros. Therefore, any request received with this *community* value would be authenticated (for example, the request would be accepted from any IP address). If the specified community name is also defined in the SNMP agent configuration file, the definition for this community name in the configuration file is overridden by specifying the community name on the `-c` parameter. This parameter is case sensitive.

The default value for this parameter is the community name *public*, but this default community name is dynamically defined to the agent only if no agent configuration file is found.

Guideline: Because the community name of *public* is a well-known name, it should not be configured to the agent due to security considerations. IBM Health Checker for z/OS can be used to check whether the community name of *public* has been configured to the SNMP agent. For more details about IBM Health Checker, see [IBM Health Checker for z/OS User's Guide](#).

-d level

Specifies the level of tracing to be started. The valid values for *level* are 0–255. If the `-d` parameter is not specified, then the default level of 0 is used, meaning no tracing is done. If the `-d` parameter is specified without a *level*, then a level of 31 is used, meaning all SNMP requests/responses/traps and DPI activity is traced.

There are eight levels of tracing provided. Each level selected has a corresponding number. The sum of the numbers associated with each level of tracing selected is the value which should be specified as *level*. If the agent is started, tracing options can be dynamically changed using the MVS MODIFY command. For more information about agent tracing, see the [z/OS Communications Server: IP Diagnosis Guide](#).

The numbers for the trace levels are:

- 0** No tracing (default)
- 1** Trace SNMP requests
- 2** Trace SNMP responses
- 4** Trace SNMP traps
- 8** Trace DPI packets
- 16** Trace DPI internals (currently, no specific traces are recorded for this trace level)
- 32** Agent internal trace
- 64** Agent internal trace plus extended storage dump traces
- 128** Agent internal trace plus extended storage dump traces and additional information

-i interval

Specifies the interval (in minutes) at which dynamic configuration changes to the SNMP agent should be written out to the SNMPD.CONF configuration file. Valid values are 0–10. The default value is 5. This parameter is only relevant when the SNMPD.CONF file is used for SNMPv3 configuration.

Guideline: Configuration updates made dynamically (by SNMP SET requests) cause the SNMPD.CONF file to be overwritten by the SNMP agent.

-p port

Listens for SNMP packets on this port. The default is port 161. If you change the port to something other than 161, you must also configure any subagents and managers, such as osnmp, to use the new port.

-s socketname

Specifies the path name of the z/OS UNIX file to be used in accepting requests from subagents that communicate with the agent by way of z/OS UNIX connections. This value can be configured either by specifying it on the -s parameter or by specifying it as the value of the dpiPathNameForUnixStream MIB object in OSNMPD.DATA. The default is /var/dpi_socket. All of the z/OS Communications Server SNMP subagents use a z/OS UNIX connection to connect to the agent.

The SNMP agent creates this path name every time it initializes. In order for subagents to successfully connect to the agent using this path name, either the subagents must be defined with superuser authority or, the file access permission bits for this path name must be set to read and write.

- If the subagent's user ID is associated with the same security product group as the SNMP agent, the Group read and write permission bits must be set.
- If the subagent's user ID is not associated with the same security product group as the SNMP agent, the Other read and write permission bits must be set.

You can use the agent's -C parameter to ensure that the agent sets the appropriate permission bits when the agent creates the path name.

For more detailed information about file access permission bits, see information about handling security for your files in [z/OS UNIX System Services User's Guide](#). If you need to change the path name's file access permission bits after the agent has initialized, you can use the z/OS UNIX chmod command. For more information about the chmod command, see [z/OS UNIX System Services Command Reference](#).

? | -help

Displays the usage statement for the command. If this parameter is specified, all other parameters are ignored. If OSNMPD was started from MVS, the usage information is written to syslogd. If OSNMPD was started from z/OS UNIX System Services, the usage information is displayed to the invoker of the command.

OSNMPD environment variables

Table 100 on page 1178 provides a list of environment variables used by OSNMPD that can be tailored to a particular installation:

Table 100. OSNMPD environment variables			
Environment variable	Server, Client or Command-type application	Description	Any specific coding rules (or a link to syntax)
OSNMPD_DATA	SNMP agent	Specifies the location of the OSNMPD.DATA configuration file.	None
PW_SRC	SNMP agent	Specifies the location of the PW.SRC configuration file.	None
SNMPD_BOOTS	SNMP agent	Specifies the location of the SNMPD.BOOTS configuration file.	None
SNMPD_CONF	SNMP agent	Specifies the location of the SNMPD.CONF configuration file.	None
SNMPTRAP_DEST	SNMP agent	Specifies the location of the SNMPTRAP.DEST configuration file.	None

OSNMPD.DATA statement syntax

The OSNMPD.DATA statements specify MIB objects and their values. The format of each statement is:

```
object_name value
```

Note:

1. There can only be one *object_name* and associated *value* per statement.
2. The *value* (if the *value* is a display or octet string) is case sensitive and is saved in mixed case.
3. Any display or octet string *value* that has imbedded white space must be enclosed in double quotation marks. For an example, see the sysDescr setting in the sample OSNMPD.DATA shipped as /usr/lpp/tcpip/samples/osnmpd.data.
4. An entry must be contained on one line.
5. Sequence numbers are not allowed on the statements.
6. Comments begin with either an asterisk (*) or a # character.

Guideline: If an error is detected in processing an entry and no appropriate default value can be assumed, the entry is discarded and an error message is written to the syslog daemon.

OSNMPD.DATA search order

The search order for accessing OSNMPD.DATA information is as follows. The first file found in the search order is used.

1. The name of a z/OS UNIX file or MVS data set specified by the OSNMPD_DATA environment variable
2. /etc/osnmpd.data z/OS UNIX file
3. The data set specified on the OSNMPD DD statement in the agent procedure
4. *jobname*.OSNMPD.DATA, where *jobname* is the name of the job used to start the SNMP agent
5. SYS1.TCPPARMS(OSNMPD)
6. *hlq*.OSNMPD.DATA, where *hlq* either defaults to TCPIP or is specified on the DATASETPREFIX statement in the TCPIP.DATA file being used

If creating a data set, you can specify a sequential data set with the following attributes: RECFM=FB, LRECL=80, and BLKSZ=3120. Other data set attributes might also work, depending on your installation parameters.

OSNMPD.DATA example

A sample of OSNMPD.DATA is installed as z/OS UNIX file /usr/lpp/tcpip/samples/osnmpd.data. This sample can be modified for your installation.

```
#

```

Figure 35. OSNMPD.DATA example

PW.SRC statement syntax

The PW.SRC statements specify community names and hosts that can use each community name. The format of a statement is:

```
community_name desired_network snmp_mask
```

The *community_name* can be up to 32 characters in length. This value can contain both uppercase and lowercase letters; however, it is case sensitive. In any requests received by the SNMP agent, the *community_name* must match the *community_name* specified in PW.SRC exactly, including the correct case.

Guideline: Because the community name of public is a well-known name, it should not be configured to the agent due to security considerations. IBM Health Checker for z/OS can be used to check whether the community name of public has been configured to the SNMP agent. For more details about IBM Health Checker, see [IBM Health Checker for z/OS User's Guide](#).

The *desired_network* is the IPv4 address in dotted decimal notation or IPv6 address in colon hexadecimal notation representing the range of addresses for which this *community_name* can be used. The *desired_network* must be specified; there is no default value.

If *desired_network* is an IPv6 address, then *snmp_mask* is either an IPv6 address mask in colon hexadecimal notation or an integer from 0 to 128 specifying the number of IPv6 address prefix bits used to construct an IPv6 address mask. The IP address mask is logically ANDed with the origin address of the incoming SNMP message.

If *desired_network* is an IPv4 address, then *snmp_mask* is either an IPv4 address mask (for example, 255.255.255.0) or an integer from 0 to 32 specifying the number of IPv4 address prefix bits used to construct an IPv4 address mask. The IP address mask is logically ANDed with the origin address of the incoming SNMP message.

Restriction: Scope information cannot be specified as part of the *desired_network* value.

If the value resulting from this logical ANDing equals the value of *desired_network*, the incoming message is accepted. *snmp_mask* must be specified; there is no default value.

- All parameters for each community must be on the same statement.
- Sequence numbers are not allowed on the statements.
- Comments begin with either an asterisk (*) or a # character.

Guidelines:

- If an error is detected in processing an entry and no appropriate default value can be assumed, the entry is discarded and an error message is written to the syslog daemon.

PW.SRC search order

The search order for accessing PW.SRC information is as follows. The first file found in the search order is used.

1. The name of a z/OS UNIX file or an MVS data set specified by the PW_SRC environment variable
2. /etc/pw.src z/OS UNIX file
3. The data set specified on SYSPWSRC DD statement in the agent procedure
4. *jobname*.PW.SRC, where *jobname* is the name of the job used to start the SNMP agent
5. SYS1.TCPPARMS(PWSRC)
6. *hlq*.PW.SRC, where *hlq* either defaults to TCPIP or is specified on the DATASETPREFIX statement in the TCPIP.DATA file being used

Because this file can only be used with SNMPv3, you should verify that there is no SNMPD.CONF file. If an SNMPD.CONF file is found, the PW.SRC file is not used.

SNMPTRAP.DEST statement syntax

The SNMPTRAP.DEST statements list managers who are to receive the traps, and the protocol used to send traps. The format of a statement is:

```
manager UDP
```

The *manager* is the host to which the trap is to be sent. This can be a host name, or it can be the IP address of the host in IPv4 dotted decimal or IPv6 colon hexadecimal notation. If a host name is specified, the value can contain both uppercase and lowercase letters and it is not case sensitive. The protocol must be UDP. There should be one entry in the data set for each host to which you want to send traps.

- All parameters for each host must be on the same statement.
- Sequence numbers are not allowed on the statements.
- Comments begin with an asterisk (*) or a # character.

Restriction: Scope information cannot be specified as part of the *manager* value.

Guidelines:

- If an error is detected in processing an entry and no appropriate default value can be assumed, the entry is discarded and an error message is written to the syslog daemon.
- If you use SNMPTRAP.DEST to configure trap information, the agent uses the hardcoded community name of public in the outbound traps. Because the community name of public is a well-known name, it should not be used in SNMP traps due to security considerations. To configure specific community names for trap destinations, you must convert your SNMPTRAP.DEST information to a SNMPD.CONF configuration file format. For more information about how to accomplish this conversion, see [“Migrating the PW.SRC file and SNMPTRAP.DEST file to the SNMPD.CONF file” on page 1203](#).

SNMPTRAP.DEST search order

The search order for accessing SNMPTRAP.DEST is as follows. The first file found in the search order is used.

1. The name of a z/OS UNIX file or an MVS data set specified by the SNMPTRAP_DEST environment variable
2. /etc/snmptrap.dest z/OS UNIX file
3. The data set specified on SNMPTRAP DD statement in the agent procedure
4. *jobname*.SNMPTRAP.DEST, where *jobname* is the name of the job used to start the SNMP agent
5. SYS1.TCPPARMS(SNMPTRAP)
6. *hlq*.SNMPTRAP.DEST, where *hlq* either defaults to TCPIP or is specified on the DATASETPREFIX statement in the TCPIP.DATA file being used

Verify that there is no SNMPD.CONF file. If an SNMPD.CONF file is found, the SNMPTRAP.DEST file is not used.

SNMPD.CONF search order

The search order for accessing SNMPD.CONF information is as follows. The first file found in the search order is used.

1. The name of a z/OS UNIX file or an MVS file specified by the SNMPD_CONF environment variable.
2. /etc/snmpd.conf

If the SNMPD.CONF file is found, the PW.SRC file and the SNMPTRAP.DEST file are not used.

SNMPD.CONF statements

If you want to migrate your community-based configuration information from the PW.SRC and SNMPTRAP.DEST files to the SNMPD.CONF file, see [“Migrating the PW.SRC file and SNMPTRAP.DEST file to the SNMPD.CONF file” on page 1203](#) for help with coding the SNMPD.CONF statements.

The SNMPD.CONF file supports the following types of entries:

USM_USER

Defines a user for the user-based security model (USM).

VACM_GROUP

Defines a security group (made up of users or communities) for the view-based access control model (VACM).

VACM_VIEW

Defines a particular set of MIB objects, called a view, for the VACM.

VACM_ACCESS

Identifies the access permitted to different security groups for the VACM.

NOTIFY

Identifies management targets to receive notifications.

NOTIFY_FILTER_PROFILE

Associates a notify filter with a particular set of target parameters.

NOTIFY_FILTER

Defines a filter profile used to filter notifications (for example, traps or informs).

TARGET_ADDRESS

Defines a management application's address and identifies parameters to be used in sending notifications or in processing requests when using community-based security.

TARGET_PARAMETERS

Defines the message processing and identifies security parameters to be used in sending notifications to a particular management target or when processing requests when using community-based security.

COMMUNITY

Defines a community for community-based security. Communities defined with this syntax are supported for compatibility purposes with the statements from the PW.SRC file, but they cannot be changed dynamically by way of SNMP SET commands. If you are defining community-based security for the first time, you should use the SNMP_COMMUNITY statement.

SNMP_COMMUNITY

Defines a community for community-based security. Communities defined with this statement can be dynamically changed by way of SNMP SET commands to the snmpCommunityTable.

The following statements must also be configured to complete the definition of a community:

- VACM_GROUP specifies the group associated with the community.
- VACM_ACCESS specifies the access allowed for the community group.
- TARGET_ADDRESS defines the address range permitted to use a particular community name and the maximum size of a response from the SNMP agent. The *transportTag* field of the SNMP_COMMUNITY statement specifies the name of the associated TARGET_ADDRESS statement.
- TARGET_PARAMETERS defines the SNMP protocol to be used with this community name.

DEFAULT_SECURITY

Identifies the default security posture configured for the SNMP agent. Additional security definitions defined by the use of the preceding eight entry definition types augment any default security configurations defined as a result of the DEFAULT_SECURITY statement.

Steps for configuring the SNMP agent for community-based security and SNMPv3 user-based security

This topic provides steps for coding the SNMPD.CONF statements required for configuring community-based security and SNMPv3 user-based security.

Steps for configuring community-based security

This topic describes the steps of configuring the SNMP agent for community-based security.

Procedure

To configure the SNMP agent for community-based security, perform the following steps:

1. For each community name, create an SNMP_COMMUNITY statement in the SNMPD.CONF file. This identifies the community names defined to the agent. For the security name field on the statement, you can use the community name, or you can define a different security name value. The value in the security name field is used to correlate the community with its associated VACM_GROUP and TARGET_PARAMETERS entries. The SNMP_COMMUNITY statement also refers to the associated TARGET_ADDRESS entry.

2. Create TARGET_ADDRESS entries to identify the address range permitted to use a particular community name. For each SNMP_COMMUNITY entry and for each range of addresses for which it is used, create a TARGET_ADDRESS entry. The TARGET_ADDRESS entries refer to related TARGET_PARAMETERS entries.

3. Create TARGET_PARAMETERS entries to identify the message processing and security models (SNMPv1 or SNMPv2c) to be used with the address on the corresponding TARGET_ADDRESS entry.

4. Define the following entries to determine which SNMP communities get access to which pieces of data and the type of access that they are allowed:

VACM_GROUP

Specify one entry for each community per security model (SNMPv1 or SNMPv2c). The security name field associates this group with its SNMP_COMMUNITY entry.

VACM_VIEW

Specify one entry for each set of MIB object identifiers that you want to protect.

VACM_ACCESS

Specify one entry that ties together the VACM_GROUP and VACM_VIEW entries and defines each group or view permission. You can define the group's permission to read, write, and receive notifications for the defined views.

5. To configure the managers to which traps or notifications should be sent, create the following entries:
 - Add one NOTIFY entry for each manager for each security model (SNMPv1 and SNMPv2c).
 - Add one TARGET_ADDRESS statement for each manager for each security model (SNMPv1 and SNMPv2c) to define the IP addresses to which traps or notification should be sent. The TARGET_ADDRESS entry references the TARGET_PARAMETERS entry where the security model is defined.
 - Add one TARGET_PARAMETERS entry to identify the security model (SNMPv1 or SNMPv2c) used in sending notifications to particular destination.
 - If you want to send the trap or notification with a community name, add an SNMP_COMMUNITY statement.

Example

Figure 36 on page 1186 shows how to define the SNMPD.CONF statements for community-based security.

```
#-----
# SNMPD.CONF file for SNMP community-based security
#-----
# VACM_GROUP entries
# Format is:
#      grpName  secModel  secName      storType
#-----
# VACM_GROUP statements for SNMP community-based security requests
VACM_GROUP group1  SNMPv1    reqsnv1    -
VACM_GROUP group1  SNMPv2c  reqsnv2c   -
# VACM_GROUP statements for traps
VACM_GROUP group2  SNMPv1    trapsnv1   -
VACM_GROUP group2  SNMPv2c  trapsnv2c  -
#-----
# VACM_VIEW entries
# Format is:
#      viewName viewSubtree viewMask viewType storType
#-----
VACM_VIEW bigView  internet  -          included -
#-----
# VACM_ACCESS entries
# Format is:

Figure 36. Example of SNMPD.CONF statements for community-based security

Steps for configuring SNMPv3 user-based security

This topic describes the steps of configuring the SNMP agent for SNMPv3 user-based security.

Procedure

To configure the SNMP agent for SNMPv3, perform the following steps to determine which SNMPD.CONF statements you need to specify:

1. Determine which SNMP users (typically managers) communicate SNMP requests to the agent. Define the USM_USER statement to define the name, the protocol, and key to authenticate messages for the user, and the protocol and key to encrypt messages for the user. The command can be used to generate the keys.

2. Determine which SNMP users get access to which pieces of data, and the type of access they are allowed. Define the following VACM_* statements:

VACM_GROUP

To identify members of a group with the same access privileges. The security model for SNMPv3 is USM.

VACM_VIEW

To identify the MIB object identifiers to which access is permitted or denied.

VACM_ACCESS

To tie together the VACM_GROUP and VACM_VIEW statements by defining the group's permission to read, write, and receive notifications for the defined views.

3. To send notifications, define the following configuration statements:

- Add one NOTIFY statement for each type of notification, such as TRAP or INFORM notifications.
- Add one TARGET_ADDRESS entry for each manager that receives a notification.
- Optionally, configure a TARGET_PARAMETERS entry to define the security parameters, such as encryption and authentication, used when sending notifications

Coding the SNMPD.CONF entries

This topic describes how to code the SNMPD.CONF entries.

Defining the USM_USER entry

```

➤➤ USM_USER — userName — engineID — authProto — authKey — privProto — privKey ➤➤
      ➤➤ keyType — storageType ➤➤

```

Defining the VACM_GROUP entry

```

➤➤ VACM_GROUP — groupName — securityModel — securityName — storageType ➤➤

```

Defining the VACM_VIEW entry

```

➤➤ VACM_VIEW — viewName — viewSubtree — viewMask — viewType — storageType ➤➤

```

Defining the VACM_ACCESS entry

➤➤ VACM_ACCESS — *groupName* — *contextPrefix* — *contextMatch* — *securityLevel* — *securityModel* →
 ➤ — *readView* — *writeView* — *notifyView* — *storageType* ➤➤

Defining the NOTIFY entry

➤➤ NOTIFY — *notifyName* — *tag* — *type* — *storageType* ➤➤

Defining the NOTIFY_FILTER_PROFILE entry

➤➤ NOTIFY_FILTER_PROFILE — *targetParamsName* — *profileName* — *storageType* ➤➤

Defining the NOTIFY_FILTER entry

➤➤ NOTIFY_FILTER — *profileName* — *filterSubtree* — *filterMask* — *filterType* — *storageType* ➤➤

Defining the TARGET_ADDRESS entry

➤➤ TARGET_ADDRESS — *targetAddrName* — *tDomain* — *tAddress* — *tagList* — *targetParams* →
 ➤ — *timeout* — *retryCount* — *storageType* — *tMask* — *tMMS* ➤➤

Defining the TARGET_PARAMETERS entry

➤➤ TARGET_PARAMETERS — *paramsName* — *mpModel* — *securityModel* — *securityName* →
 ➤ — *securityLevel* — *storageType* ➤➤

Defining the COMMUNITY entry

➤➤ COMMUNITY — *communityName* — *securityName* — *securityLevel* — *netAddr* — *netMask* →
 ➤ — *storageType* ➤➤

Defining the SNMP_COMMUNITY entry

➤➤ SNMP_COMMUNITY — *communityIndex* — *communityName* — *securityName* — *contextEngineID* →
 ➤ — *contextName* — *transportTag* — *storageType* ➤➤

Defining the DEFAULT_SECURITY entry

➤➤ DEFAULT_SECURITY — *securityPosture* — *password* — *privacy* ➤➤

Parameters

USM_USER entry

USM_USER *userName* *engineID* *authProto* *authKey* *privProto* *privKey* *keyType* *storageType*

Field definitions

userName

Indicates the name of the user for the User-Based Security Model (USM). The userName must be unique to the SNMP agent. The userName is used as the security name for the User-based Security Model; the contents of this field are used as the securityName value for other entries (such as the VACM_GROUP entry) when the securityModel is USM. The userName field is a 1–32 character string. There is no default value.

engineID

Indicates the engineID of the authoritative side of the message. The engineID for the z/OS Communications Server SNMP agent is determined at agent initialization; it is either read in from the SNMPD.BOOT file or it is generated automatically and stored in the SNMPD.BOOT file. It can be retrieved dynamically by issuing a get request for object snmpEngineID.0. Use the following information to determine which engineID should be specified for a user:

- For get, getbulk, set, response, and trap messages, the authoritative side is the SNMP agent. Therefore, either specify its engineID or use a dash (-) for the default value.
- For inform messages, the authoritative side is the notification receiver. Therefore, you must configure the engineID of the notification receiver.

Valid values are a string of 2–64 hexadecimal digits or a dash (-) to indicate the default value (the local SNMP agent's engineID).

authProto

Indicates the authentication protocol to be used on authenticated messages on behalf of this user. The following values are valid:

- HMAC-MD5
- HMAC-SHA
- none. Indicates that no authentication is to be done.
- dash (-). Indicates the default value, which is HMAC-MD5.

authKey

Indicates the authentication key to be used in authenticating messages on behalf of this user. This field is ignored when authProto is specified as none. The keyType field indicates whether the key is localized or nonlocalized. Valid values are 32 hexadecimal digits when authProto is HMAC-MD5 and 40 hexadecimal digits when authProto is HMAC-SHA. A (-) dash indicates the default (no key, indicating no authentication). For information about generating authentication and privacy keys using the pwtokey command, see [z/OS Communications Server: IP System Administrator's Commands](#).

privProto

Indicates the privacy protocol to be used on encrypted messages on behalf of this user. Privacy can be requested only if authentication is also requested. If authentication is not requested, this field is ignored. The following values are valid:

DES

Indicates CBC 56-bit DES.

AESCFB128

Indicates AES 128-bit CFB mode.

none

Indicates no privacy.

dash (-)

Indicates the default value, which is no privacy.

Requirement: For the AES privacy protocol, z/OS Integrated Cryptographic Service Facility (ICSF) must be active. For detailed information about configuring ICSF, see [z/OS Cryptographic Services ICSF Administrator's Guide](#).

privKey

Is used in authenticating messages to and from this user. This field is ignored when *privProto* is specified as none. The *keyType* field indicates whether the key is localized or nonlocalized. Privacy can be requested only if authentication is also requested. If authentication is not requested, this field is ignored. The privacy key and the authentication key are assumed to have been generated using the same authentication protocol (HMAC-MD5 or HMAC-SHA). Valid values are 32 hexadecimal digits if the key is localized or if the key is nonlocalized and the *authProto* is HMAC-MD5; 40 hexadecimal digits if the key is nonlocalized and the *authProto* is HMAC-SHA; or a dash (-) to indicate the default of no key, indicating no encryption. For information about generating privacy keys using the *pwtkey* command, see [z/OS Communications Server: IP System Administrator's Commands](#).

keyType

Indicates whether the keys defined by *authKey* and *privKey* are localized or nonlocalized. Localized indicates that they have been generated with the appropriate *engineID*, making the key usable only at one *snmpEngine*. If you use this user to send inform messages and localize the key, you must use the *engineID* of the notification receiver in the localized key. The notification receiver must define the user keys as nonlocalized. A nonlocalized key indicates that the key can be used at different *snmpEngines*. The *authKey* and *privKey*, if both are specified, must both be localized or both be nonlocalized. This field is ignored if no authentication or privacy is requested. Valid values are L to indicate keys are localized, N to indicate keys are nonlocalized, or a dash (-) to indicate the default value of localized.

storageType

Indicates the type of storage in which this definition is to be maintained. Storage types are defined in RFC 1903. Note that the value of *volatile* is not supported in the *SNMPD.CONF* file. Valid values are:

nonVolatile

Indicates the entry definition persists across reboots of the SNMP agent, but it can, however, be changed or even deleted by dynamic configuration requests.

permanent

Indicates the entry definition persists across reboots of the SNMP agent; it can be changed but not deleted by dynamic configuration requests.

readonly

Indicates the entry definition persists across reboots of the SNMP agent; it cannot be changed or deleted by dynamic configuration requests. For the *USM_USER* entry, *readOnly* is not allowed unless the authentication protocol is none because protocols require that user keys be changeable.

dash (-)

Indicates the default value of *nonVolatile*.

VACM_GROUP entry

```
VACM_GROUP groupName securityModel securityName storageType
```

Field definitions

groupName

The group name for the View-Based Access Control Model (VACM). The *groupName* must be specified; there is no default value. It must be a 1 - 32 character string.

securityModel

Indicates the SNMP security model for this entry. When an SNMP message comes in, the *securityModel* and the *securityName* are used to determine the group to which the user (or community) represented by the *securityName* belongs. Valid values are *SNMPv1* to indicate community-based security using *SNMPv1* message processing; *SNMPv2c* to indicate community-based security using *SNMPv2c* message processing; *USM* to indicate the User-Based Security Model; or a dash (-) to indicate the default value of *USM*.

Rule: The SNMP Getbulk request and the retrieval of Counter64 MIB object values are not supported for SNMPv1 message processing. For users who want to use these functions, you must configure the users to belong to a group whose security model is SNMPv2c or USM.

securityName

Indicates a member of this group. Valid values are 1–32 characters and indicate one of the following members:

- A USM *userName* when *securityModel* is USM
- A *securityName* from an SNMP_COMMUNITY statement whose community is associated with this group
- A *securityName* from a COMMUNITY statement whose community is associated with this group. In this case the *securityName* is the community name.

There is no default value.

storageType

Indicates the type of storage in which this definition is to be maintained. Storage types are defined in RFC 1903. Note that the value of volatile is not supported in the SNMPD.CONF file. Valid values are:

nonVolatile

Indicates the entry definition persists across reboots of the SNMP agent; it can, however, be changed or even deleted by dynamic configuration requests.

permanent

Indicates the entry definition persists across reboots of the SNMP agent; it can be changed but not deleted by dynamic configuration requests.

readonly

Indicates the entry definition persists across reboots of the SNMP agent; it cannot be changed or deleted by dynamic configuration requests.

dash (-)

Indicates the default value of nonVolatile.

VACM_VIEW entry

```
VACM_VIEW viewName viewSubtree viewMask viewType storageType
```

Field definitions

viewName

Indicates the textual name of the view for the View-Based Access Control Model. View names do not need to be unique. Multiple entries with the same name together define one view. However, the *viewName*, together with the subtree object ID, must be unique to an SNMP engine. Valid values are 1–32 characters in length. There is no default value.

viewSubtree

Indicates the MIB object prefix of the MIB objects in the view. Valid values are an object ID of up to 128 sub-OIDs, a textual object name (or object prefix), or a combination of textual object name followed by numeric sub-OIDs. The name must be found within the compiled MIB or in the logical extension to the MIB, the /etc/mibs.data file. There is no default value.

Guideline: For views that govern notify operations (traps or informs), the *viewSubtree* and *viewMask* are used to verify access to all the MIB objects in the notification, and access to the notification OID (for example, the value in the *snmpTrapOID* MIB object). All notifications that the SNMP agent sends include the following MIB objects:

- *sysUpTime*
- *snmpTrapOID*
- *snmpTrapEnterprise*

Therefore, the most granular viewSubtree that can be specified for notifications is internet (an OID of 1.3.6.1) to permit the members of a group access to these standard notification MIB objects.

viewMask

Indicates a mask that specifies which of the sub-OIDs in the subtree are relevant. See RFC 3415 for further information about the *viewMask*. Valid values are a hex string of up to 16 bytes (up to 128 bits), where each hexadecimal digit represents four bits. Each bit indicates whether or not the corresponding sub-OID in the subtree is relevant, or a dash (-) to indicate the default value (a mask of all ones meaning all sub-OIDs are relevant).

viewType

Indicates the type of the view definition. Valid values are included to indicate the MIB objects identified by this view definition are within the view, excluded to indicate the MIB objects identified by this view definition are excluded from the view, or a dash (-) to indicate the default value of included.

storageType

Indicates the type of storage in which this definition is to be maintained. Storage types are defined in RFC 1903. Note that the value of volatile is not supported in the SNMPD.CONF file. Valid values are:

nonVolatile

Indicates the entry definition persists across reboots of the SNMP agent; it can, however, be changed or even deleted by dynamic configuration requests.

permanent

Indicates the entry definition persists across reboots of the SNMP agent; it can be changed but not deleted by dynamic configuration requests.

readonly

Indicates the entry definition persists across reboots of the SNMP agent; it cannot be changed or deleted by dynamic configuration requests.

dash (-)

Indicates the default value of *nonVolatile*

VACM_ACCESS entry

```
VACM_ACCESS groupName contextPrefix contextMatch securityLevel  
securityModel readView writeView notifyView storageType
```

Field definitions

groupName

The group name for the View-Based Access Control Model (VACM) for which access is being defined. The *groupName* must be specified; there is no default value. It must be a 1–32 character string.

contextPrefix

Indicates a character string to be compared with the incoming contextName, if the value specified for the contextMatch field is prefix. Note, however, that the SNMP agent in z/OS Communications Server supports MIB objects in only the local (null) context. Valid values are 1–32 characters, or a dash (-) to indicate the default value of the null context ("").

contextMatch

Indicates whether the incoming contextName must be compared with (and match exactly) the entire contextName or whether only the first part of the contextName (up to the length of the indicated value of the contextPrefix) must match. Valid values are exact to indicate that the entire contextName must match, prefix to indicate that only the prefix of the contextName must match, or a dash (-) to indicate the default value of exact.

securityLevel

Indicates the securityLevel for this entry and is used in determining which access table entry to use. Valid values are noAuthNoPriv or none to indicate no authentication or privacy protocols are applied; AuthNoPriv or auth to indicate authentication protocols are applied but no privacy protocol is applied; AuthPriv or priv to indicate both authentication and privacy protocols are applied; or a dash (-) to indicate the default value of noAuthNoPriv.

securityModel

Indicates the SNMP security model for this entry and is used in determining which access table entry to use. Valid values are SNMPv1 to indicate community-based security using SNMPv1 message processing, SNMPv2c to indicate community-based security using SNMPv2c message processing, USM to indicate the User-Based Security Model, or a dash (-) to indicate the default value of USM.

readView

Indicates the name of the view to be applied when read operations (get, getnext, getbulk) are performed under control of this entry in the access table. Valid values are 1–32 characters identifying a view defined by a VACM_VIEW definition or a dash (-) to indicate the default value of no view (no readView defined for members of this group). If no view is defined, read operations fail with access authorization errors for the members of the group.

writeView

Indicates the name of the view to be applied when write operations (set) are performed under control of this entry in the access table. Valid values are 1–32 characters identifying a view defined by a VACM_VIEW definition or a dash (-) to indicate the default value of no view (no writeView defined for members of this group). If no view is defined, write operations fail with access authorization errors for the members of the group.

notifyView

Indicates the name of the view to be applied when notify operations (traps or informs) are performed under control of this entry in the access table. Valid values are 1–32 characters identifying a view defined by a VACM_VIEW definition or a dash (-) to indicate the default value of no view (no notifyView defined for members of this group). If no view is defined, notify operations fail with access authorization errors for the members of the group.

storageType

Indicates the type of storage in which this definition is to be maintained. Storage types are defined in RFC 1903. Note that the value of volatile is not supported in the SNMPD.CONF file. Valid values are:

nonVolatile

Indicates the entry definition persists across reboots of the SNMP agent; it can, however, be changed or even deleted by dynamic configuration requests.

permanent

Indicates the entry definition persists across reboots of the SNMP agent; it can be changed but not deleted by dynamic configuration requests.

readonly

Indicates the entry definition persists across reboots of the SNMP agent; it cannot be changed or deleted by dynamic configuration requests.

dash (-)

Indicates the default value of nonVolatile.

NOTIFY entry

```
NOTIFY notifyName tag type storageType
```

Field definitions**notifyName**

A locally unique identifier for this notify definition. Valid values are 1–32 characters in length. There is no default value.

tag

Indicates a tag value to be compared with the values in the tagLists defined in the snmpTargetAddrTable (either on TARGET_ADDRESS entries or by way of dynamic configuration). For each match of this tag with a value in the tagLists defined in the snmpTargetAddrTable, a notification can be sent. See RFC 2573 for a definition of SnmpTagValue. Valid values are 1 - 255 characters. No delimiters are allowed. A dash (-) indicates the default, which is no tag value.

type

Indicates which type of notification should be generated. Valid values are:

- A trap; an unconfirmed notification; notification sent with trap PDUs
- An inform; a confirmed notification; notification sent with inform PDUs
- dash (-) Indicates the default value of trap

storageType

Indicates the type of storage in which this definition is to be maintained. Storage types are defined in RFC 1903. Note that the value of volatile is not supported in the SNMPD.CONF file. Valid values are:

nonVolatile

Indicates the entry definition persists across reboots of the SNMP agent, but it can, however, be changed or even deleted by dynamic configuration requests.

permanent

Indicates the entry definition persists across reboots of the SNMP agent; it can be changed but not deleted by dynamic configuration requests.

readonly

Indicates the entry definition persists across reboots of the SNMP agent; it cannot be changed or deleted by dynamic configuration requests.

dash (-)

Indicates the default value of nonVolatile.

NOTIFY_FILTER_PROFILE entry

```
NOTIFY_FILTER_PROFILE targetParamsName profileName storageType
```

Field definitions

targetParamsName

Indicates the name of the target parameter definition (paramsName in the TARGET_PARAMETERS entry) for which the specified notify filter profile is used. Valid values are 1 - 32 characters in length. There is no default value.

profileName

Indicates the name of the notify filter profile (profileName on the NOTIFY_FILTER entry) used. Valid values are 1–32 characters in length. There is no default value.

storageType

Indicates the type of storage in which this definition is to be maintained. Storage types are defined in RFC 1903. Note that the value of volatile is not supported in the SNMPD.CONF file. Valid values are:

nonVolatile

Indicates the entry definition persists across reboots of the SNMP agent, but it can, however, be changed or even deleted by dynamic configuration requests.

permanent

Indicates the entry definition persists across reboots of the SNMP agent; it can be changed but not deleted by dynamic configuration requests.

readonly

Indicates the entry definition persists across reboots of the SNMP agent; it cannot be changed or deleted by dynamic configuration requests.

dash (-)

Indicates the default value of nonVolatile.

NOTIFY_FILTER entry

```
NOTIFY_FILTER profileName filterSubtree filterMask filtertype storageType
```

Field definitions

profileName

Indicates the name of the filter profile defined by this entry. Valid values are 1–32 characters. There is no default value.

filterSubtree

Identifies the MIB subtree that, when combined with the corresponding filterMask, defines a family of subtrees which are included in or excluded from the filter profile. Valid values are an object ID of up to 128 sub-OIDs or a textual object name (or object prefix). There is no default value.

filterMask

Indicates the bit mask that, in combination with the corresponding filterSubtree, defines a family of subtrees that are included in or excluded from the filter profile. See RFC 2573 for a definition of the viewMask. Valid values are a hex string of up to 16 octets (up to 128 bits). Each bit indicates whether or not the corresponding subtree sub-OID is relevant, or a dash (-) to indicate the default value (a mask of all ones meaning that all sub-OIDs are relevant). inform indicates a confirmed notification (for example, notification sent with inform PDUs).

filterType

Indicates whether the family of filter subtrees defined by this entry are included in or excluded from a filter. Valid values are included to indicate the MIB objects identified by this definition are within the filter, excluded to indicate the MIB objects identified by this definition are excluded from the filter, or a dash (-) to indicate the default value of included.

storageType

Indicates the type of storage in which this definition is to be maintained. Storage types are defined in RFC 1903. Note that the value of volatile is not supported in the SNMPD.CONF file. Valid values are:

nonVolatile

Indicates the entry definition persists across reboots of the SNMP agent, but it can, however, be changed or even deleted by dynamic configuration requests.

permanent

Indicates the entry definition persists across reboots of the SNMP agent; it can be changed but not deleted by dynamic configuration requests.

readonly

Indicates the entry definition persists across reboots of the SNMP agent; it cannot be changed or deleted by dynamic configuration requests.

dash (-)

Indicates the default value of nonVolatile.

TARGET_ADDRESS entry

```
TARGET_ADDRESS targetAddrName tDomain tAddress tagList targetParams
timeout retryCount storageType tMask tMMS
```

Field definitions

targetAddrName

Indicates a locally unique identifier for this target address definition. Valid values are 1–32 characters in length. There is no default value.

tDomain

Indicates the transport type of the address indicated by *tAddress*. Valid values are UDP, UDP6, or a dash (-) for the default value of UDP. If *tAddress* is an IPv6 colon hexadecimal address, the value UDP6 must be used; otherwise, if *tAddress* is an IPv4 dotted decimal address, then UDP or a dash (-) must be used.

tAddress

For notifications, *tAddress* indicates the transport address and port to which notifications are sent. For community-based security, *tAddress* indicates the value that is used to determine whether the IP address and port of an SNMP request should be permitted to the community name.

- For IPv4 *tAddress* values, specify an IPv4 dotted decimal address that is optionally followed by two periods and a port number (for example, 10.10.1.1..1162). You can use a colon instead of two periods to separate the IPv4 address value from the port number (for example, 10.10.1.1:1162).
- For IPv6 *tAddress* values, specify an IPv6 address in colon hexadecimal notation that is optionally followed by two periods and a port number (for example, 2001:0db8::1..1162).

For community-based security, when an SNMP request is received, the IP address mask portion of the *tMask* value is logically ANDed with the origin address of the request. The resulting value must equal the value of *tAddress* for the SNMP request to be permitted to the community name. The *tagList* value is used to find the community name.

tagList

For notifications, *tagList* indicates a list of tag values that are used to select target addresses for a notification operation. For community-based security, the *tagList* value is used to find the associated SNMP_COMMUNITY statement containing the community name used for verification of the IP address of an SNMP request. The z/OS Communications Server implementation supports, by way of the configuration file, only one tag in a tag list. RFC 2573 contains the complete definition of *SnmpTagList* and *SnmpTagValue*. The z/OS Communications Server implementation accepts as valid values a string of 1–255 characters. No delimiters are allowed. A dash (-) indicates the default value, an empty list.

targetParams

For notifications, *targetParams* indicates a TARGET_PARAMETERS *paramsName* value that indicates which security and message processing is to be used when sending notifications to this target. For community-based security, *targetParams* indicates the TARGET_PARAMETERS *paramsName* value that contains the security module to be used to determine whether an SNMP request should be permitted to a community name. Valid values are 1–32 characters in length. There is no default value.

timeout

Indicates the expected maximum round-trip time for communicating with this target address (in 1/100ths of a second). Valid values are 0 - 2147483647, or a dash (-) to indicate the default value of 1500. Timeout is used only for inform type notifications; it is not used for traps.

retryCount

Indicates the number of retries to be attempted when a response is not received for a generated message. Valid values are 0 - 255, or a dash (-) to indicate the default value of 3. RetryCount is used only for inform type notifications; it is not used for traps.

Guideline: The timeout and retryCount parameters are used only for inform processing. The agent can only support 10 concurrent informs. For those informs for which the agent has not received a response and whose timeout value has expired, the agent will resend the inform, up to the retryCount value. Once the retryCount has been exceeded, the agent discards the inform packet. If the agent is already tracking 10 informs when the 11th inform is created, the agent will create a trace message for this error but will discard the inform. To determine what to configure for the timeout and retryCount values, you might need to determine:

- The volume and frequency of asynchronous notifications that are being generated by the subagents.
- The response of the inform receiver to the informs.

storageType

Indicates the type of storage in which this definition is to be maintained. Storage types are defined in RFC 1903. Note that the value of volatile is not supported in the SNMPD.CONF file. Valid values are:

nonVolatile

Indicates the entry definition persists across reboots of the SNMP agent; it can, however, be changed or even deleted by dynamic configuration requests.

permanent

Indicates the entry definition persists across reboots of the SNMP agent; it can be changed but not deleted by dynamic configuration requests.

readonly

Indicates the entry definition persists across reboots of the SNMP agent; it cannot be changed or deleted by dynamic configuration requests.

dash (-)

Indicates the default value of nonVolatile.

tMask

Indicates the IP address mask and port mask associated with this Target Address entry. If *tAddress* is an IPv4 dotted decimal address, then *tMask* must be either an IPv4 address mask in dotted decimal notation or an IPv4 prefix value (0-32), optionally followed by two periods and a port mask (for example, 255.255.0.0.65535). A colon can be used instead of two periods to separate the IPv4 address mask or prefix value from the port mask if a port mask is specified (for example, 255.255.0.0:65535). If *tAddress* is an IPv6 colon hexadecimal address, then *tMask* must be either an IPv6 address mask in colon hexadecimal notation or an IPv6 prefix value (0-128), optionally followed by two periods and a port mask (for example, 48..65535). A dash (-) specified for *tMask* indicates the default value. If *tAddress* is an IPv4 dotted decimal address, the default *tMask* value is 255.255.255.255..65535. If *tAddress* is an IPv6 colon hexadecimal address, the default *tMask* value is 128..65535.

Guideline: The default port mask is 65535, regardless if the port is specified in the *tAddress* field.

tMMS

Indicates the maximum message size value associated with this target address entry. Valid values are in the range 0 - 2147483647. A dash (-) indicates the default, which is 484. When the TARGET_ADDRESS statement is used as part of the definition of an SNMP community name, this parameter controls the size of the response from the SNMP agent.

TARGET_PARAMETERS entry

```
TARGET_PARAMETERS paramsName mpModel securityModel securityName
securityLevel storageType
```

Field definitions***paramsName***

A locally unique identifier for this target parameters definition. Valid values are 1–32 characters in length. There is no default value.

mpModel

For notifications, *mpModel* is the message processing model to be used in sending notifications to targets with this parameter definition. For community-based security, *mpModel* designates the SNMP protocol of the SNMP requests received from the IP address defined by the associated TARGET_ADDRESS statement. Valid values are SNMPv1, SNMPv2c, and SNMPv3. There is no default value.

securityModel

For notifications, *securityModel* indicates the security model to be used in sending notifications to targets with this parameter definition. For community-based security, *securityModel* designates the SNMP protocol of the SNMP request to be used, along with the IP address, to determine whether the IP address should be permitted to the community name. Valid values are SNMPv1, SNMPv2c, or USM to indicate User-Based Security Model. There is no default value.

securityName

For notifications, *securityName* identifies the principal (user or community) on whose behalf SNMP messages are generated using this parameter definition. For community-based security, this is the *securityName* value from the associated SNMP_COMMUNITY statement. For user-based security, this

is a *userName* value from a USM_USER statement. Valid values are 1 - 32 characters in length. There is no default value.

securityLevel

Indicates the security level to be used in sending notifications to targets with this parameter definition. Valid values are noAuthNoPriv or none to indicate no authentication or privacy protocols are applied, AuthNoPriv or auth to indicate that authentication protocols are applied but no privacy protocol is applied, AuthPriv or priv to indicate that both authentication and privacy protocols are applied (If the additional encryption product is not applied, this level can be configured, but not actually used), or a dash (-) to indicate the default value of noAuthNoPriv. For community-based security, specify the default value of a dash(-).

storageType

Indicates the type of storage in which this definition is to be maintained. Storage types are defined in RFC 1903. Note that the value of volatile is not supported in the SNMPD.CONF file. Valid values are:

nonVolatile

Indicates the entry definition persists across reboots of the SNMP agent; it can, however, be changed or even deleted by dynamic configuration requests.

permanent

Indicates the entry definition persists across reboots of the SNMP agent; it can be changed but not deleted by dynamic configuration requests.

readonly

Indicates the entry definition persists across reboots of the SNMP agent; it cannot be changed or deleted by dynamic configuration requests.

dash (-)

Indicates the default value of nonVolatile.

COMMUNITY entry

```
COMMUNITY communityName securityName securityLevel netAddr netMask storageType
```

Field definitions

communityName

The community name for community-based security (SNMPv1 or SNMPv2c). The *netAddr* must be specified; there is no default value. It must be a 1 - 32 character string.

Guideline: Because the community name of public is a well-known name, it should not be configured to the agent due to security considerations. IBM Health Checker for z/OS can be used to check whether the community name of public has been configured to the SNMP agent. For more details about IBM Health Checker, see [IBM Health Checker for z/OS User's Guide](#).

securityName

The *securityName* defined for this *communityName*. The *securityName* is the more generic term for the principal (user or community) for which other entries, such as VACM_GROUP and TARGET_PARAMETERS, are defined. The community name must match the *securityName* exactly. The *securityName* is 1 - 32 characters. A dash (-) indicates the default value; a *securityName* equal to the specified *communityName*.

securityLevel

Indicates the security level to be applied when processing incoming or outgoing messages with this community name. Valid values are noAuthNoPriv or none to indicate no authentication or privacy protocols are applied, or dash (-) to indicate the default value of noAuthNoPriv. Encryption is not supported on SNMPv1 and SNMPv2c messages.

netAddr

The host IP address or network address, in IPv4 dotted decimal or IPv6 colon hexadecimal notation, representing the range of addresses for which this community name can be used. When an SNMP request is received, the *netMask* value is logically ANDed with the origin address of the request.

The resulting value must equal the value of *netAddr* for the SNMP request to be permitted to the community name. The *netAddr* must be specified; there is no default value.

netMask

The IP address mask or IP address prefix defined for this *communityName*. If *netAddr* is an IPv6 colon hexadecimal address, then *netMask* is either an IPv6 colon hexadecimal address mask (for example, FFFF:FFFF::) or an integer from 0 to 128 specifying the number of IPv6 address prefix bits used to construct an IPv6 address mask. If *netAddr* is an IPv4 dotted decimal address, then *netMask* is either an IPv4 address mask (for example, 255.255.255.0) or an integer from 0 to 32 specifying the number of IPv4 address prefix bits used to construct an IPv4 address mask. The mask is logically ANDed with the origin address of the incoming SNMP message. If the resulting value equals the value of *netAddr*, the incoming message is accepted. *netMask* must be specified; there is no default value.

storageType

Indicates the type of storage in which this definition is to be maintained. Storage types are defined in RFC 1903. Note that the value of *volatile* is not supported in the SNMPD.CONF file. Valid values are:

nonVolatile

Indicates the entry definition persists across reboots of the SNMP agent; it can, however, be changed or even deleted by dynamic configuration requests.

permanent

Indicates the entry definition persists across reboots of the SNMP agent; it can be changed but not deleted by dynamic configuration requests.

readonly

Indicates the entry definition persists across reboots of the SNMP agent; it cannot be changed or deleted by dynamic configuration requests.

dash (-)

Indicates the default value of *nonVolatile*.

SNMP_COMMUNITY entry

```
SNMP_COMMUNITY communityIndex communityName securityName contextEngineID  
contextName transportTag storageType
```

Field definitions

communityIndex

Indicates a locally unique identifier for this SNMP_Community definition. Valid values are 1 - 32 characters in length. There is no default value.

communityName

The community name for community-based security (SNMPv1 or SNMPv2c) . Valid values are 1 - 32 characters in length. There is no default value. The agent assumes that community names are encoded in ASCII. If an EBCDIC-encoded community name is needed, it must be specified as a UTF-8 name. See the Usage Note topic for an explanation about how to configure a UTF-8 name.

Guideline: Because the community name of *public* is a well-known name, it should not be configured to the agent due to security considerations. IBM Health Checker for z/OS can be used to check whether the community name of *public* has been configured to the SNMP agent. For more details about IBM Health Checker, see [IBM Health Checker for z/OS User's Guide](#).

securityName

The *securityName* defined for this *communityName*. The *securityName* is the more generic term for the principal (user or community) for which other entries, such as VACM_GROUP and TARGET_PARAMETERS, are defined. Valid values are 1 - 32 characters in length. There is no default value.

contextEngineID

Indicates the location of the context in which information is accessed. A dash (-) indicates the default value of the local SNMP agent's engine ID. Only the default value is supported.

contextName

The corresponding context value. Valid values are 1-32 characters in length. Only a dash (-) indicating the default, which is an empty string, is supported.

transportTag

Indicates a tag value to be compared with the values in the tagLists defined in the snmpTargetAddrTable (either on TARGET_ADDRESS entries or by way of dynamic configuration). Those target addresses (whose tag value match this tag) identify the transport endpoints from which a request containing this community are accepted. Valid values are 1 - 255 characters. No delimiters are allowed. A dash (-) indicates the default, which is no tag value.

storageType

Indicates the type of storage in which this definition is to be maintained. Valid values are:

nonVolatile

Indicates the entry definition persists across reboots of the SNMP agent; it can, however, be changed or even deleted by dynamic configuration requests.

permanent

Indicates the entry definition persists across reboots of the SNMP agent; it can be changed but not deleted by dynamic configuration requests.

readonly

Indicates the entry definition persists across reboots of the SNMP agent; it cannot be changed or deleted by dynamic configuration requests.

dash (-)

Indicates the default value of nonVolatile.

DEFAULT_SECURITY entry

DEFAULT_SECURITY *securityPosture password privacy*

Field definitions**securityPosture**

Indicates the default security posture to be configured for the SNMP agent, as defined by Appendix A of RFC 2575. Valid values are minimum-secure to indicate the SNMP agent is configured with the least secure default configurations; semi-secure to indicate the SNMP agent is configured with moderately secure default configurations; and no-access to indicate the SNMP agent is configured with no default configurations. The default value is no-access.

Following are the default security definitions based on the selected security posture:

no-access

No initial configurations are done.

semi-secure

If privacy is not requested, a default user is configured as if the following USM_USER entry had been specified:

```
USM_USER initial- HMAC-MD5 ### none - N permanent
```

where ### indicates the key generated from the password specified on the DEFAULT_SECURITY entry.

If privacy is requested, a default user is configured as if the following USM_USER entry had been specified:

```
USM_USER initial - HMAC-MD5 ### DES ### N permanent
```

where ### indicates the key generated from the password specified on the DEFAULT_SECURITY entry.

A default group is configured as if the following VACM_GROUP entry had been specified:

```
VACM_GROUP initial USM initial readOnly
```

Three default access entries are configured as if the following VACM_ACCESS entries had been specified:

```
VACM_ACCESS initial - exact none USM restricted - restricted readOnly
VACM_ACCESS initial - exact auth USM internet internet internet readOnly
VACM_ACCESS initial - exact priv USM internet internet internet readOnly
```

Two default MIB views are configured as if the following VACM_VIEW entries had been specified:

```
VACM_VIEW internet internet - included readOnly
VACM_VIEW restricted system - included readOnly
VACM_VIEW restricted snmp - included readOnly
VACM_VIEW restricted snmpEngine - included readOnly
VACM_VIEW restricted snmpMPDStats - included readOnly
VACM_VIEW restricted usmStats - included readOnly
```

minimum-secure

If privacy is not requested, a default user is configured as if the following USM_USER entry had been specified:

```
USM_USER initial - HMAC-MD5 ### none - N permanent
```

where ### indicates the key generated from the password specified on the DEFAULT_SECURITY entry.

If privacy is requested, a default user is configured as if the following USM_USER entry had been specified:

```
USM_USER initial - HMAC-MD5 ### DES ### N permanent
```

where ### indicates the key generated from the password specified on the DEFAULT_SECURITY entry.

A default group is configured as if the following VACM_GROUP entry had been specified:

```
VACM_GROUP initial USM initial readOnly
```

Three default access entries are configured as if the following VACM_ACCESS entries had been specified:

```
VACM_ACCESS initial - exact none USM restricted - restricted readOnly
VACM_ACCESS initial - exact auth USM internet internet internet readOnly
VACM_ACCESS initial - exact priv USM internet internet internet readOnly
```

Two default MIB views are configured as if the following VACM_VIEW entries had been specified:

```
VACM_VIEW internet internet - included readOnly
VACM_VIEW restricted internet - included readOnly
```

password

Indicates the password to be used to generate authentication and privacy keys for user initial. If no-access is specified as the *securityPosture*, this keyword is ignored. Valid values are 8 - 255 characters string, or a dash (-) to indicate the default value (no password). The default is only accepted if *securityPosture* is no-access.

privacy

Indicates whether or not encryption is to be supported for messages on behalf of user 'initial'. Valid values are Yes to indicate that privacy is supported for user initial, No to indicate that privacy is not supported for user initial, or a dash (-) to indicate the default value of no. If no-access is selected as the security posture, this value is ignored.

Usage notes

- The SNMP Agent supports the ASCII character set and UTF-8 encoding for the values specified for the name fields on the configuration statements. Use UTF-8 values to define EBCDIC name field values to the agent. To specify a UTF-8 value for a name field, specify the value in the following format:
 - The first character must be a cent sign (¢)
 - The remaining characters are the octet string representing the name value

For example, to define the EBCDIC value, TEST, in a name field, specify the name value as follows:

```
¢e3c5e2e3
```

- If an error is detected in processing an entry and no appropriate default value can be assumed, the entry is discarded and an error message is written to the syslog daemon.
- An entry must be contained on one line.
- Keywords in the SNMPD.CONF file are accepted in any case (that is, they are not case sensitive.)
- Values in the SNMPD.CONF file are case sensitive. For example, a userName of user1 is not equivalent to a userName of USER1.
- All of these entry definitions require that all fields be specified, either with a specific value or with a dash (-). A dash indicates that the appropriate default value should be applied.
- If an error is detected in processing an entry and no appropriate default value can be assumed, the entry is discarded and an error message is generated.
- Statements in the SNMPD.CONF file are not order dependent. However, if more than one DEFAULT_SECURITY statement is found, the last one in the file is the one that is used.
- If there are no valid entries in the SNMPD.CONF file (but the file exists) and no -c parameter specified at agent invocation, no requests are accepted.
- Comments can be entered in the SNMPD.CONF file. They must begin with an asterisk (*) or a # character in column 1.
- The SNMP agent uses a ¢ character to precede a hex string that represents a value for an SnmpAdminString syntax object for which the value cannot be printed. Use of the ¢ is reserved for this purpose. Do not change the contents of the entries in the configuration file that have a ¢ character preceding them.
- You cannot specify scope information about any values in the SNMPD.CONF file that represent IP addresses or host names.

SNMPD.CONF sample

The following code shows the SNMPD.CONF sample:

```
# snmpd.conf sample
#
# Sample file showing format of configuration file for the SNMP agent
#
# Licensed Materials - Property of IBM
# "Restricted Materials of IBM"
# 5650-ZOS # Copyright IBM Corp. 1997, 2015 # Status = CSV2R2
# SMP/E distribution path: /usr/lpp/tcpip/samples/IBM/EZASNDCO
#
#-----
# Notes
# - All values for an entry must be on the same line.
# - Dynamic changes to the SNMP agent configuration made by SNMP SET
#   commands may cause entries to be written to this file that are
#   wider than the original entries. If this file is maintained in
#   an MVS data set, the record length should allow for longer entries.
# - All localized keys need to be regenerated using the pwtkey command
#   in order for these sample entries to actually be used.
# - In this sample:
#   - Keys are generated for use with engineID 0000000200000000943714F
#   - Authentication keys were generated with password of
#     username+"password", such as "u1password"
#   - Privacy keys were generated with password of
#     username+"privpass", such as "u1privpass"
```

```

Migrating the PW.SRC file and SNMPTRAP.DEST file to the SNMPD.CONF file

If you want to continue to use community-based security (for SNMP protocols, SNMPv1 and SNMPv2c), but take advantage of some of the new SNMPv3 functions, or if you want to use the new SNMPV3 user-based security along with community-based security, you need to migrate your current configuration, defined in the PW.SRC and SNMPTRAP.DEST files, to the SNMPD.CONF format.

Steps for migrating the PW.SRC and SNMPTRAP.DEST files

This topic describes the steps of migrating the PW.SRC and SNMPTRAP.DEST files to the SNMPD.CONF file.

Procedure

Perform the following steps to migrate the PW.SRC and SNMPTRAP.DEST files to the SNMPD.CONF file:

1. For each community name defined in the the PW.SRC file, create an SNMP_COMMUNITY statement in the SNMPD.CONF file. This identifies the community names defined to the agent.

-
2. Create TARGET_ADDRESS entries to identify the address range permitted to use a particular community name. For each SNMP_COMMUNITY entry and for each range of addresses for which it is used, create a TARGET_ADDRESS entry. The TARGET_ADDRESS entries refer to related TARGET_PARAMETERS entries.
-
3. Create TARGET_PARAMETERS entries to identify the security model (SNMPv1 or SNMPv2c) to be used with the address on the corresponding TARGET_ADDRESS entries.
-
4. Define the following entries to determine which SNMP communities get access to which pieces of data and the type of access that they are allowed:
VACM_GROUP
Specify one entry for each security model (in this case SNMPv1 or SNMPv2c) and use the community names from the PW.SRC file.
VACM_VIEW
Specify one entry for each set of MIB object identifiers that you want to protect.
VACM_ACCESS
Specify one entry that ties together the VACM_GROUP and VACM_VIEW entries and defines each group/view permission. You can define the group's permission to read, write, and receive notifications for the defined views.
-
5. To continue sending notifications, convert the entries in the SNMPTRAP.DEST file to entries in the SNMPPD.CONF file.
 - Add one NOTIFY entry for type TRAP.
 - Add one TARGET_ADDRESS statement for each manager that receives a TRAP.
 - Optionally, configure a TARGET_PARAMETERS entry to identify the message model used in sending notifications to particular destinations. The default is SNMPv1, or specify SNMPv2c. Encryption and authentication are not used.
-

Results

Tip: For more detailed information about migrating z/OS SNMP configuration files from SNMPv1 and SNMPv2c to SNMPv3, see Technote Migrating z/OS SNMP to SNMPv3 at <http://www.ibm.com/support/docview.wss?uid=swg27004972>.

Example

For an example of using SNMPPD.CONF statements to configure community-based security, see [Figure 36 on page 1186](#).

SNMPPD.BOOTs statement syntax

The syntax is:

engineID engineBoots

where:

engineID

A string of 2–64 (must be an even number) hexadecimal digits. The engine identifier uniquely identifies the agent within an administrative domain. By default, the engine identifier is created using a vendor-specific formula and incorporates the IP address of the agent. However, a customer can

choose to use any engine identifier that is consistent with the `snmpEngineID` definition in RFC 3411 and that is also unique within the administrative domain.

engineBoots

The number of times (in decimal) the agent has been restarted since the `engineID` was last changed.

Note:

1. `engineID` and `engineBoots` must be specified in order and on the same line.
2. Comments are specified in the file by starting the line with either an asterisk (*) or a # character.
3. No comments are allowed between the `engineID` and `engineBoots` values.
4. Only the first non-comment line is read. Subsequent lines are ignored.
5. If an error is detected in processing an entry and no appropriate default value can be assumed, the entry is discarded and an error message is written to the syslog daemon.

SNMPD.BOOTs search order

The search order for accessing SNMPD.BOOTs information is as follows. The first file found in the search order is used.

1. The name of a z/OS UNIX file or an MVS data set specified by the `SNMPD_BOOTs` environment variable.
2. `/etc/snmpd.boots`

Guideline: If the `SNMPD.BOOTs` file is not provided, the SNMP agent creates the file. If multiple SNMPv3 agents are running on the same MVS image, use the environment variable to specify different `SNMPD.BOOTs` files for the different agents. For security reasons, ensure unique `engineIDs` are used for different SNMP agents.

SNMP query engine (SNMPQE)

This topic describes the SNMP query engine (SNMPQE).

SNMP query engine cataloged procedure (SNMPPROC)

This topic shows the `SNMPPROC` cataloged procedure.

```
//SNMPQE  PROC MODULE=SQESERV,PARMS=' '

```

Figure 38. SNMP query engine cataloged procedure (SNMPPROC)

Specifying the SNMPQE parameters

The SQESERV module can be configured to start without parameters or you can add any of the following parameters to `PARMS='` in the PROC statement of the SNMPQE cataloged procedure. For example,

```
//SNMPQE  PROC MODULE=SNMPQE,PARMS='-h MVSA'
```

Note:

1. These parameters are also valid when starting SNMPQE with the START command.
2. The commands are case sensitive. They must be entered in lowercase.
3. When starting SNMPQE in batch, do not use the 'POSIX(ON)' parameter. This alters the search order the query engine uses to find the configuration files, which could prevent it from locating any configuration files not explicitly pointed to using a standard environment variable. It can also have other unexpected results.

Parameter

Description

-d *trace_level*

Specifies the level of tracing to be run. Valid values for the trace level are:

- 0**
No tracing (default)
- 1**
Displays errors
- 2**
In addition to errors, also displays SNMP query engine protocol packets sent and received
- 3**
In addition to 2, also displays the SNMP packets sent and received
- 4**
In addition to 3, also displays the buffers in hexadecimal format

-h *host_name*

Specifies the IP address to which to bind, so that SQESERV accepts connections only through that IP address. This parameter is useful if multiple IP addresses exist for a single host, and you want to restrict access from one side.

-it

Specifies that a trace of IUCV communication be done. This is only used for debugging the socket layer in a user's application. It can result in a large amount of STDOUT output.

-tp *port_number*

Specifies the port at which the SNMP Query Engine listens for traps. If this option is not specified, the SNMP Query Engine listens on the well-known port 162. The valid values are 1 - 65 535.

See [z/OS Communications Server: IP Diagnosis Guide](#) for more information about tracing.

SNMP parameter data set (SNMPARMS) sample

Following is the SNMPARMS sample:

```
*-----*

SNMPRETO 2    * Retry backoff exponent (1=linear, 2=exponential)
SNMPMMLL 80    * Line length for Multiline Messages 38/44
```

Figure 39. SNMP parameter data set (SNMPARMS) sample

Specifying the SNMPARMS parameters

You can change the following parameters in SNMPARMS:

Parameter Description

SNMPQE name

The name of the SNMP query engine started procedure. This value is case sensitive. The default address space name is SNMPQE. If you change the name of the SNMP query engine started procedure, you must change this parameter to match the new procedure name.

SNMPQERT seconds

The retry timer, in seconds, for IUCV CONNECT. When SNMPIUCV is started, it tries to connect to the SNMP query engine. If the connection fails or breaks, SNMPIUCV retries a connect every *n* seconds, as specified by this parameter. The valid range of values is 0 - 9999. The default is 60 seconds.

SNMPRCNT *number*

The retry count for sending SNMP requests. This is the number of times the SNMP query engine resends an SNMP PDU when no response was received. If no response is received after all retries have been exhausted, the SNMP query engine returns a no response error for the SNMP request. The valid range of values is 0 - 255. The default is 2.

If the request being sent by the SNMP query engine contains a community name that is not valid, no response is received. This causes the SNMP query engine to resend the request until the retry count is exhausted. If authentication failure traps are enabled, the agent generates multiple **authentication-Failure** traps, one for the initial request and one for each of the retries.

SNMPMMLL *length*

The line length for multiline messages 38 and 44. The maximum length is 255. A value of 80 allows the complete text to appear on an 80-character-wide screen. The default and minimum acceptable line length value is 80.

SNMPRETO *exp*

The retry back-off exponent. Specifies whether the timeout value between retries of an SNMP request is calculated linearly or exponentially. The valid values are 1 (linear) or 2 (exponential). The default is 2.

For example, if the retry timeout was 1 second, SNMPRETO of 1 causes a new retry to be sent at constant 1-second intervals until all retries have been sent. SNMPRETO of 2 causes the first retry to be sent after 1 second, the second retry 2 seconds later, the third retry 4 seconds later, and so on until all retries have been sent.

SNMPRITO *tenths_seconds*

The timeout value for a request specified in tenths of a second. After sending an SNMP request to an agent, the SNMP query engine waits the specified number of tenths of a second for a response.

- If the retry count (SNMPRCNT) is greater than 0, the SNMP request is sent again if a response is not received in this time.
- If the retry count (SNMPRCNT) is 0, a no response error is sent to the NetView program, if a response is not received within this period of time.

The valid range of values is 0 - 255. The default is 10 tenths of a second.

MIBDESC.DATA statement

The MIBDESC.DATA statement syntax is:

```
short_name asn.1_name type time_to_live
```

where:

- *short name* is the textual name for the MIB object, either as defined in the MIB definition or chosen by the customer.
- *asn.1_name* is the MIB object identifier that describes the location of the object in the MIB tree.
- *type* is the syntax of the MIB object.
- *time_to_live* is the number of seconds the SNMP Query Engine can cache the object before requesting an updated copy from the SNMP agent.

The following SNMP variable type values (from SMI version 1) are supported in the type field of the MIBDESC.DATA statement:

- Number for integers
- String for octet strings
- Object for object identifiers
- Internet for IP addresses
- Counter for counters (unsigned)

- Gauge for gauge (unsigned)
- Ticks for time ticks
- Display for display strings
- Table for table header variables
- Empty for no value

MIBDESC.DATA search order

The search order for accessing MIBDESC.DATA is as follows. The first file found in the search order is used.

1. The name of a z/OS UNIX file or an MVS data set specified by the MIB_DESC environment variable.
2. *hlq*.MIBDESC.DATA, where *hlq* either defaults to TCPIP or is specified on the DATASETPREFIX statement in the TCPIP.DATA file being used .

MIBDESC environment variables

Table 101 on page 1209 provides a list of environment variables used by MIBDESC that can be tailored to a particular installation:

Table 101. MIBDESC environment variables			
Environment variable	Server, Client or Command-type application	Description	Any specific coding rules (or a link to syntax)
MIB_DESC	SNMP Query Engine	Specifies the location of the MIBDESC.DATA configuration file	None

z/OS UNIX snmp command

This topic describes the z/OS UNIX snmp command.

Environment variables

Table 102 on page 1209 provides a list of environment variables used by the command that you can modify to use with your installation environment:

Table 102. z/OS UNIX snmp command environment variables			
Environment variable	Server, Client or Command-type application	Description	Any specific coding rules (or a link to syntax)
MIBS_DATA	z/OS UNIX snmp command	Specifies the location of the MIBS.DATA configuration file.	None
OSNMP_CONF	z/OS UNIX snmp command	Specifies the location of the OSNMP.CONF configuration file.	None

OSNMP.CONF search order

The following search order for this file enables different copies of the file to be used by different users:

1. A z/OS UNIX file or MVS data set pointed to by the OSNMP_CONF environment variable

2. /etc/osnmp.conf
3. /etc/snmpv2.conf

OSNMP.CONF statement syntax

The configuration file is required when sending requests to the SNMPv2 or SNMPv3 nodes in your network. The configuration file can also be used to send SNMPv1 requests.

The syntax of a statement in the configuration file is:

```
winSNMPname targetAgent admin secName password context secLevel  
authProto authKey privProto privKey NOSVIPA
```

Field definitions

winSNMPname

An administrative name that the snmp command uses to locate an entry in the configuration file. There is no default value. This field is specified on the -h option (maximum 32 characters).

targetAgent

Host name or IP address (IPv4 dotted decimal or IPv6 colon hexadecimal) of the node of the target agent (maximum 80 characters). There is no default value. To direct the command to a port other than 161, specify *host..port#* (with two periods between the host and port number). For example, for port 222 at mvs150, specify mvs150..222. Port number, if specified, must be in the range of 1 to 65535. If the host is specified by a host name or an IPv4 dotted decimal address and a port number is also specified, a colon (:) can be used to separate the two values instead of two periods.

admin

Specifies the administrative model supported by the targetAgent. Valid values are:

- snmpv1 - Community-based SNMPV1 security
- snmpv2c - Community-based SNMPV2 security
- snmpv3 - User-based SNMPV3 security

There is no default value.

Rule: The SNMP Getbulk request and the retrieval of Counter64 MIB object values are not supported for SNMPv1 message processing. To use these functions, you must configure a winSNMPname entry with the SNMPv2c or SNMPv3 security model and use that winSNMPname entry when sending requests to the targetAgent.

secName

Specifies the security name of the principal using this configuration file entry. For user-based security, this is the userName. The user must be defined at the targetAgent. This field is ignored unless snmpv3 is specified for the admin keyword. A valid value is a user name of 1–32 characters. There is no default.

password

Specifies the password to be used in generating the authentication and privacy keys for this user. If a password is specified, it is used to automatically generate any needed keys and the "authKey" and "privKey" fields below are ignored. This field is ignored unless snmpv3 is specified for the admin keyword. If no password is desired, set field to a single dash (-). (The minimum is eight characters, and the maximum is 64 characters.)

Guideline: You should not use the password instead of keys in this configuration file, because using keys is more secure than storing passwords in this file.

context

The SNMP contextName to be used at the target agent. The contextName is needed only at agents that support multiple contexts; otherwise, the only context supported is the null context, which is the default value of this keyword. The z/OS Communications Server SNMP agent does not support

multiple contexts. This field is ignored unless `snmpv3` is specified for the `admin` keyword. If the blank "" context selector is desired, set this field to a single dash (-). (The maximum is 32 characters).

secLevel

Specifies the security level to be used in communicating with the target SNMP agent when this entry is used. This field is ignored unless `snmpv3` is specified for the `admin` keyword. Valid values are `noAuthNoPriv` or `none` to indicate that no authentication or privacy is requested; `AuthNoPriv` or `auth` to indicate that authentication is requested but privacy is not requested; `AuthPriv` or `priv` to indicate that both authentication and privacy are requested; or a dash (-) to indicate the default value (`noAuthNoPriv`).

authProto

SNMP authentication protocol to be used in communicating with the target SNMP agent when this entry is used. This field is ignored unless `snmpv3` is specified for the `admin` keyword. The following values are valid:

- HMAC-MD5
- HMAC-SHA
- dash (-). Indicates no authentication.

authKey

Specifies the SNMP authentication key to be used in communicating with the target SNMP agent when this entry is used. This key must be the nonlocalized key. This field is ignored if the `password` keyword is used. This field is ignored unless `snmpv3` is specified for the `admin` keyword and a nondefault value is specified for `authProto`. Valid values are 16 bytes (32 hex digits) when `authProto` is HMAC-MD5 and 20 bytes (40 hex digits) when `authProto` is HMAC-SHA. A dash (-) indicates the default value, which is no key.

privProto

Specifies the SNMP privacy protocol to be used in communicating with the target SNMP agent when this entry is used. This field is ignored unless `snmpv3` is specified for the `admin` keyword. The following values are valid:

DES

Indicates CBC-DES.

AESCFB128

Indicates AES 128-bit CFB mode.

dash (-)

Indicates the default value, which is no privacy.

Requirement: For the AES privacy protocol, ICSF must be active. For detailed information about configuring ICSF, see [z/OS Cryptographic Services ICSF Administrator's Guide](#).

privKey

Specifies the SNMP privacy key to be used in communicating with the target SNMP agent when this entry is used. This key must be the nonlocalized key. This field is ignored if the `password` keyword is used. The privacy and authentication keys are assumed to have been generated using the same authentication protocol (for example, both with HMAC-MD5 or both with HMAC-SHA). This field is ignored unless `snmpv3` is specified for the `admin` keyword and a nondefault value is specified for `privProto`. Valid values are 16 bytes (32 hex digits) when `authProto` is HMAC-MD5, 20 bytes (40 hex digits) when `authProto` is HMAC-SHA, or a dash (-) to indicate the default value (no key).

NOSVIPA

The `NOSVIPA` keyword is an optional value. If specified, it indicates the `osnmp` command should cause physical interface addresses to be used as the originating address in packets sent by the `osnmp` command to this host. `NOSVIPA` is disabled by default, meaning that `SOURCE` VIPA addresses can be used. If specified, `NOSVIPA` must be either the fourth parameter (for community-based security) or the twelfth parameter (for user-based security).

Statement syntax rules

- All parameters for an entry must be contained on one line in the configuration file.
- A dash (-) indicates the default value for a keyword.
- Sequence numbers are not allowed on the statements.
- Comments begin with a # character in column 1.
- The secName and password parameters are case sensitive.
- The pwtokey command can be used to generate the authentication and privacy keys. For information about the pwtokey command, see [z/OS Communications Server: IP System Administrator's Commands](#).
- Because the osnmp command supports both issuance of SNMP requests and receipt of SNMP traps, the entries in the OSNMP.CONF file must be defined for both uses. Multiple entries for the same USM user are allowed within the file. This can be useful when defining different security levels for the same user. If multiple entries for the same USM user are defined, be aware that only the first one in the file can be used for receiving notifications. If multiple entries for the same USM user are defined and the user receives notifications, the definition with the highest (most stringent) securityLevel should be defined first. Doing so allows the user to be used for any level of security equal to or lower (less stringent) than the securityLevel defined.

Restriction: You cannot specify scope information about any values in the OSNMP.CONF file that represent IP addresses or host names.

OSNMP.CONF sample

Requirement: The osnmp command requires that all fields for a given entry are specified on a single line. For readability, the following sample has been formatted such that long entries are wrapped to the next line.

```
# osnmp.conf sample
# (used as /etc/snmpv2.conf unless OSNMP_CONF environment variable set)
#
# Sample file showing format of configuration file for the osnmp command

```

Figure 40. OSNMP.CONF sample

MIBS.DATA statement syntax

The MIBS.DATA statements can be used to specify character (usually called textual) names for MIB objects not defined in any compiled MIB supplied with z/OS Communications Server. You can then use these character/textual names as the name of the objects on the osnmp command.

The format of a statement in this file is:

```
character_object_name object_identifier object_type
```

Field definitions

character_object_name

The character or textual name of the MIB object. The *character_object_name* value can contain both uppercase and lowercase letters.

object_identifier

The ASN.1 value for the MIB object.

object_type

The SMI_type for the MIB object. The valid SMI_type values are:

- bitstring
- counter
- counter32
- counter64
- dateAndTime
- display or display string
- integer

- integer32
 - ipaddress
 - gauge
 - gauge32
 - nsapaddress
 - null
 - objectidentifier or OID
 - octetstring
 - opaque
 - opaqueascii
 - snmpAdminString
 - timeticks
 - uinteger
- The maximum length of each statement in this file is 2048 bytes.
 - All parameters for each character or textual name must be on the same statement.
 - Sequence numbers are not allowed on the statements.
 - Comments begin with a # character in column 1.

MIBS.DATA search order

The search order for accessing the MIBS.DATA information is as follows. The first file found in the search order is used.

- The name of a z/OS UNIX file or an MVS data set specified by the MIBS_DATA environment variable
- /etc/mibs.data z/OS UNIX file

TRAPFWD daemon

The TRAPFWD daemon forwards traps from the SNMP agent to network management applications. It listens for traps on port 162 and forwards them to all configured managers.

Starting TRAPFWD from an MVS console

Update cataloged procedure TRAPFWD by copying the sample in SEZAINST(TRAPFWD) to your system.

The following is a sample JCL Procedure for starting TRAPFWD from MVS:

```

//TRAPFWD  PROC
//*
//* Sample procedure for running the z/OS UNIX Trap Forwarder daemon
//*
//* z/OS Communications Server Version 1 Release 7
//* SMP/E Distribution Name: SEZAINST(EZASNTPR)
//*
//*
//* Copyright:    Licensed Materials - Property of IBM
//*              5694-A01
//*              (C) Copyright IBM Corp. 2000, 2005
//*
//* Status:      CSV1R7
//*
//TRAPFWD EXEC PGM=EZASNTRA,REGION=4096K,TIME=NOLIMIT,
//  PARM='POSIX(ON) ALL31(ON)/-d 0'
//*
//*** Notes:
//*
//* - The C runtime libraries should be in the system's link list
//*   or this sample procedure will need to STEPLIB to them.
//*
//* - TCP/IP runtime libraries should also be in the system's link
//*   list.
//*
//* - TRAPFWD must find the name (TCPIPJOBNAME in TCPIP.DATA) that
//*   it should be associated with. The OE function __iptcpn() is
//*   used to find this name. It is suggested that the parmlist
//*   be modified to set the environment variable
//*   RESOLVER_CONFIG to point to the correct resolver file when
//*   multiple INET Physical File Systems are started.
//*
//*   If only one INET PFS will be started then /etc/resolv.conf
//*   may be used.
//*
//* - The TRAPFWD daemon can also be invoked from the OMVS shell as
//*   a shell command.
//*
//*
//SYSPRINT DD SYSOUT=*,DCB=(RECFM=F,LRECL=80,BLKSIZE=80)
//SYSIN    DD DUMMY
//SYSERR   DD SYSOUT=*
//SYSOUT   DD SYSOUT=*,DCB=(RECFM=F,LRECL=80,BLKSIZE=80)
//CEEDUMP  DD SYSOUT=*

```

Figure 41. TRAPFWD cataloged procedure

Specifying TRAPFWD parameters

The following parameters are available for TRAPFWD:

Parameter Description

-d *n*

The -d flag indicates the level of debug information that is desired. The valid values are:

- 0 - No tracing
- 1 - Minimal tracing. Ttrace address from which the trap is received.
- 2 - In addition to 1, trace addresses to which the trap packet is forwarded.
- 3 - In addition to 2, trace trap packets.

If the -d parameter is not specified, the default value of 0 is used.

-p *port_number*

The -p flag indicates the UDP port at which the daemon should listen for traps. The default is UDP port 162.

-l *max_packet_len*

The -l flag indicates the maximum packet length of the trap datagram that has to be forwarded. The valid values are 4096 (4K) to 16384 (16K). The default value is 4096. Note that if the

ADD_RECVFROM_INFO option is specified, then the maximum packet size is be max_packet_len minus the length of the address information.

-?

The -? flag displays the usage statement for the trap forwarder daemon. If the -? option is specified, all the other options are ignored.

TRAPFWD environment variables

Table 103 on page 1216 provides a list of environment variables used by TRAPFWD that can be tailored to a particular installation:

Table 103. TRAPFWD environment variables			
Environment variable	Server, Client or Command-type application	Description	Any specific coding rules (or a link to syntax)
TRAPFWD_CONF	TRAPFWD daemon	Specifies the location of the TRAPFWD.CONF configuration file	None

Starting TRAPFWD from the UNIX shell

The trapfwd command is used to start the trap forwarder daemon.

To start TRAPFWD from the UNIX shell:

TRAPFWD.CONF statement syntax

The format of a statement in this file is:

```
host_name port_number number
```

Field definitions

host_name

The host name or IP address (IPv4 dotted decimal or IPv6 colon hexadecimal) to which the trap should be forwarded. If a dash (-) is used, then the local host name is used.

Restriction: Scope information cannot be specified for the *host_name* value.

port_number

The port number to which the trap should be forwarded. There is no default value.

number

This field is optional. If a value of ADD_RECVFROM_INFO is specified, the received from information is appended to the trap. The default is not to append the received from information.

Usage notes

Lines starting with an asterisk (*) or a # character are considered comment lines.

TRAPFWD.CONF search order

The following search order is used to access the TRAPFWD.CONF information:

1. A z/OS UNIX file or an MVS data set specified by the TRAPFWD_CONF environment variable
2. /etc/trapfwd.conf

The first file found in the search order is used.

If the environment variable is set and if the file specified by the environment variable is not found, the Trap Forwarder daemon terminates.

TRAPFWD examples

To start the trap forwarder daemon on the standard port (port 162), enter:

```
# trapfwd
```

To start the trap forwarder daemon on a particular port (port 5062), enter:

```
# trapfwd -p 5062
```

Chapter 20. Remote print server

This topic contains the following information:

- [“LPD server cataloged procedure \(LPSPROC\)” on page 1219](#)
- [“Sample LPD server configuration data set \(LPDDATA\)” on page 1220](#)
- [“Specifying LPD server parameters” on page 1222](#)
- [“Summary of LPD server configuration statements” on page 1222](#)
- [“LPD server configuration data set statements” on page 1223](#)

LPD server cataloged procedure (LPSPROC)

The following sample shows the Remote print server (LPD) server cataloged procedure (LPSPROC).

```

//LPSERVE  PROC MODULE=LPD,
//          LPDDATA=TCPIP.SEZAINST(LPDDATA),
//          LPDPRFX='PREFIX TCPIP',
//          DIAG=''
//*
//*          z/OS Communications Server
//*          SMP/E Name: EZAEB019 alias LPSPROC in library SEZAINST

//*          SYSERR contains runtime diagnostics from Pascal. It can be
//*          a data set or SYSOUT.
//*
//SYSERR DD SYSOUT=*
//*
//*          SYSDEBUG receives output that is generated when the TRACE
//*          parameter is specified in the PARM on the EXEC card.
//*          It can be a data set or SYSOUT.
//*
//SYSDEBUG DD SYSOUT=*
//OUTPUT DD SYSOUT=*
//SYSIN DD DUMMY
//*
//*          The SYSDUMP DD statement will cause MVS to provide
//*          an IPCS readable dump for ABENDs.
//*SYSDUMP DD DISP=SHR,DSN=your.dump.data.set
//*
//*          SYSTCPD explicitly identifies which data set is to be
//*          used to obtain the parameters defined by TCPIP.DATA
//*          when no GLOBALTCPIPDATA statement is configured.
//*          See the IP Configuration Guide for information on
//*          the TCPIP.DATA search order.
//*          The data set can be any sequential data set or a member of
//*          a partitioned data set (PDS).
//SYSTCPD DD DISP=SHR,DSN=TCPIP.SEZAINST(TCPDATA)

```

Figure 42. LPD Server cataloged procedure (LPSPROC)

Sample LPD server configuration data set (LPDDATA)

The following sample shows the LPD server configuration data set (LPDDATA).

```

;LPD CONFIGURATION DATA SET
;=====
;
; COPYRIGHT = NONE.
; Change Activity
; $L1=MV11199 HTP320 951206 RTPMCL: Added comments
; $01=PN66730 HTP310 960131 RTPMCL: Added change flag
;      =MV14695 TCPV34 970910 YANG : Removed sequence numbers
;      =MV15117 TCPV34 970929 AGIUS : Added OBEY statement
;
; This data set describes the printers and punches (which are both
; called SERVICE) that are usable from LPR client programs for this
; host.
;

```

```

; Each SERVICE must be described as LOCAL, NJE, or REMOTE. Data for
; LOCAL services are managed directly by JES. Data for NJE services
; are managed by NJE. REMOTE services' data are forwarded to another
; LPD (print server).
;
; You can control which types of printing or punching can be done
; through a particular SERVICE with FILTERS. The 4 currently
; available FILTERS are:
;
;     f    which paginates the data set at the size of the page given.
;           It also truncates lines if they exceed a maximum length.
;     l    which does not insert pagination but will truncate lines
;           as the "f" filter does.
;     p    which paginates the data set, adding titles, the date, and
;           page numbers as well as providing line truncation.
;     r    which prints the data set, interpreting the first column
;           of each line as FORTRAN carriage control.
;
; Most printer SERVICES should allow all three but you probably only
; want to specify "l" for punches.
;
; The LINESIZE option can be used to limit the length of lines written
; by the filters.
;
; The PAGESIZE option can be used for filters that do pagination to
; specify how many lines should appear on a page.
;
; The RACF option will cause the server to verify that a user knows
; the account password for a user ID on this host.
;
; These statements define a LOCAL PRINTER SERVICE called locprt1, which
; is a conventional printer that will use the JES printing facilities.
;
;DEBUG
SERVICE locprt1 PRINTER
  LOCAL
  FILTERS f l p r
  LINESIZE 132
  PAGESIZE 60
;
; These statements define an NJE PRINTER SERVICE called njeprt1, which
; provides access to the NJE service on this system.
;
SERVICE njeprt1 PRINTER
;   NJE DEST=RALVMM IDENTIFIER=JOHN OUTPUT=LPD1
;   FILTERS f l p r
;   LINESIZE 132
;   PAGESIZE 60
;
; These statements define a REMOTE SERVICE called pebprt, which
; provides access to the printing queues on another system.
; From an LPR client, specify the printer name defined on the SERVICE
; statement and the hostname or IP address of the host that this LPD
; is running on, NOT the names on the REMOTE statement.
;   Example: LPR fn (p pebprt h LPDSrvHostName
; The above is required if you wish to send the data to the REMOTE
; printer via this LPD.
;
SERVICE pebprt PRINTER
;   REMOTE lpt1@PEBBLES.TCP.RALEIGH.IBM.COM
;   FAILEDJOB MAIL
;
; These statements define a PUNCH SERVICE called pun1, which
; provides access to the JES controlled PUNCH.
;
SERVICE pun1 PUNCH
  LOCAL
  FILTERS l
  LINESIZE 80
;
; This statement specifies user IDs authorized to use the SMSG
; interface provided with LPD server. The syntax is "OBEY user_id",
; where "user_id" is the list of authorized user IDs. The following
; example allows three test user IDs to use the SMSG interface:
;
OBEY TESTER01 TESTER02 TESTER03
;

```

Figure 43. Sample LPD server configuration data set (LPDDATA)

Specifying LPD server parameters

The system parameters required by the LPD server are passed by the PARM option on the EXEC statement of the LPD cataloged procedure. Update the following parameters as required.

LPDDATA='data_set_name'

Specifies the fully qualified name of the data set containing the LPD configuration statements.

Guideline: This data set can be sequential or a member of a PDS.

LPDPRFX='PREFIX your_prefix'

Specifies the high-level qualifier to be used for temporary data sets created by the LPD server. Include both the PREFIX keyword and your qualifier in the quoted string. The qualifier can be up to 26 characters. If it is blank, it defaults to the procedure name. The LPD task requires the authority to create and modify data sets with this prefix.

DIAG='options'

Specifies any of the following diagnostic options in a quoted string of keywords separated by blanks. For example, DIAG= 'VERSION TRACE '

VERSION

Displays the version number.

TYPE

Activates high-level trace facility in the LPD server. Significant events, such as the receipt of a job for printing, are recorded in the //SYSOUT DD data set specified in your LPD server cataloged procedure.

TRACE

Causes a detailed trace of activities within the LPD server to record in the //SYSOUT DD data set specified in your LPD server cataloged procedure.

Tip: The detailed tracing can also be activated with the DEBUG statement in the LPD server configuration data set and with the TRACE command of the SMSG interface.

Restriction: The JCL PARM= statement has a limit of 100 characters.

Summary of LPD server configuration statements

The valid statements for this data set are listed in the following table.

Table 104. Summary of LPD server configuration statements

Statement	Description	See
DEBUG	Turns on tracing of all LPD processes.	“DEBUG statement” on page 1223
JOBPACING	Restricts parallel processing of jobs to conserve memory.	“JOBPACING statement” on page 1223
OBEY	Specifies users IDs that can use the SMSG interface.	“OBEY statement” on page 1224
SERVICE	Specifies the name and Type of Service.	“SERVICE statement” on page 1224
STEPLIMIT	Restricts complexity of jobs received to conserve memory.	“STEPLIMIT statement” on page 1233
UNIT	Specifies type of DASD that LPD should use for temporary data sets.	“UNIT statement” on page 1233
VOLUME	Specifies the volume that LPD should use for temporary data sets.	“VOLUME statement” on page 1234

LPD server configuration data set statements

This topic includes the syntax rules and alphabetically listed definitions of the statements for the data set used to configure the LPD Server.

Syntax rules

In the LPD server configuration data set, tokens are delimited by blanks and record boundaries. All characters to the right of and including a semicolon are treated as comments.

DEBUG statement

Use the DEBUG statement to activate full tracing of the processing within the LPD server.

Syntax

➡ DEBUG ➡

Parameters

There are no parameters for this statement.

Usage notes

- Detailed tracing can also be activated using the TRACE parameter on the PROC statement of the LPD server procedure or by specifying TRACE ON with the SMSG interface. The DEBUG statement can be placed anywhere in the data set but only affects those services following it. Including DEBUG as the first statement in the configuration data set allows trace messages to be written from the point LPD is initialized.
- LPD generates minimal tracing under the following conditions:
 - No value in DIAG parameter
 - TRACE not passed as a parameter
 - DEBUG not defined in the LPD configuration file
- Coding LPD with DIAG=Version results in minimal tracing plus the message EZB0614I. Coding LPD with DIAG=Type results in minimal tracing plus brief messages describing JOB status, such as:
 - JOBreceived
 - JobStartPRINTING
 - JOBcontinuePRINTING
 - JOBfinishPRINTINGCoding LPD with DIAG=Trace results in configuration messages and details of print job.
- TRACE passed as a parameter yields the same results coding DIAG=TYPE.

JOBPACING statement

Use the JOBPACING statement to limit the number of jobs that the LPD server concurrently writes to the JES spool or send to another LPD server. This limits memory requirements in LPD, but does not cause any jobs to be lost. Received jobs are queued until they can be processed.

Syntax

Parameters

limit

An integer specifying the maximum number of jobs that the LPD server concurrently writes to the JES spool or send to another LPD server.

Usage notes

- Concurrent processing of jobs requires memory for control blocks and large I/O buffers. Some concurrent job processing keeps a long job or slow receiving LPD from delaying all the other jobs. Too much concurrent processing causes thrashing and requires extensive memory.
- JOB PACING defaults to the preferred value 5 when the keyword is not specified. Increasing this value might cause memory allocation problems with certain system configurations.
- If LPD runs out of memory, reduce the value of either JOB PACING or STEPLIMIT.

OBEY statement

Use the OBEY statement to specify user IDs authorized to use the SMSG interface provided with LPD server.

Syntax

Parameters

user_id

The user IDs authorized to use the SMSG interface. See [z/OS Communications Server: IP Configuration Guide](#) for more information.

Examples

Code the following statement to allow three test user IDs to use the SMSG interface:

```
OBEY TESTER01 TESTER02 TESTER03
```

Usage notes

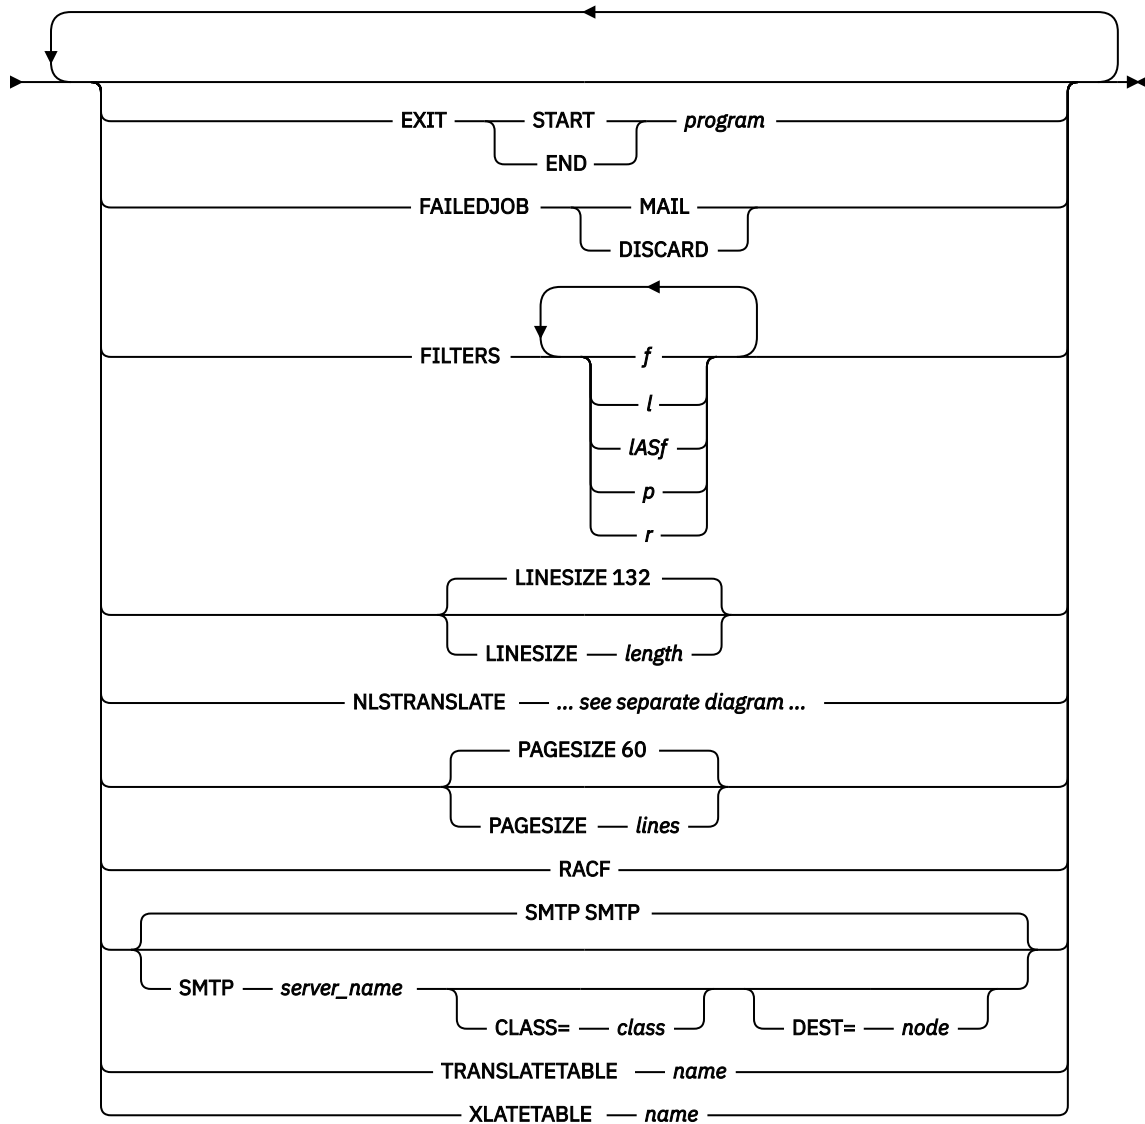

Multiple user IDs can be specified on the OBEY statement. More than one OBEY statement can be included in the data set.

SERVICE statement

Use the SERVICE statement to specify the name and Type of Service for the printers and punches used by the LPD server. This service name is used in the LPR command.

Requirement: The parameters shown on separate lines must be coded on separate lines. Follow the example in the sample configuration data set shown in [“Sample LPD server configuration data set \(LPDDATA\)”](#) on page 1220.

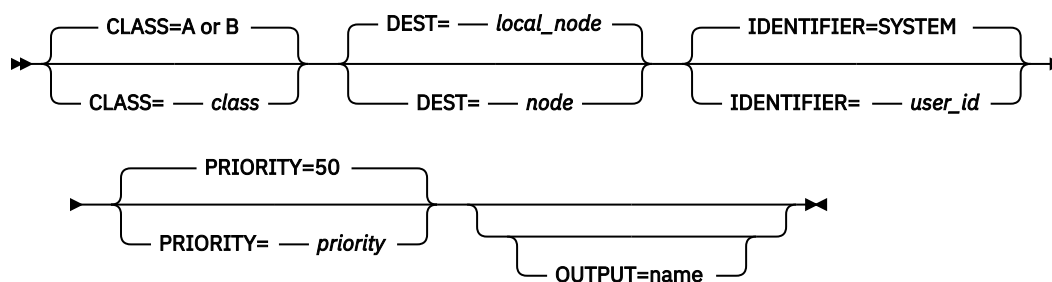

Syntax

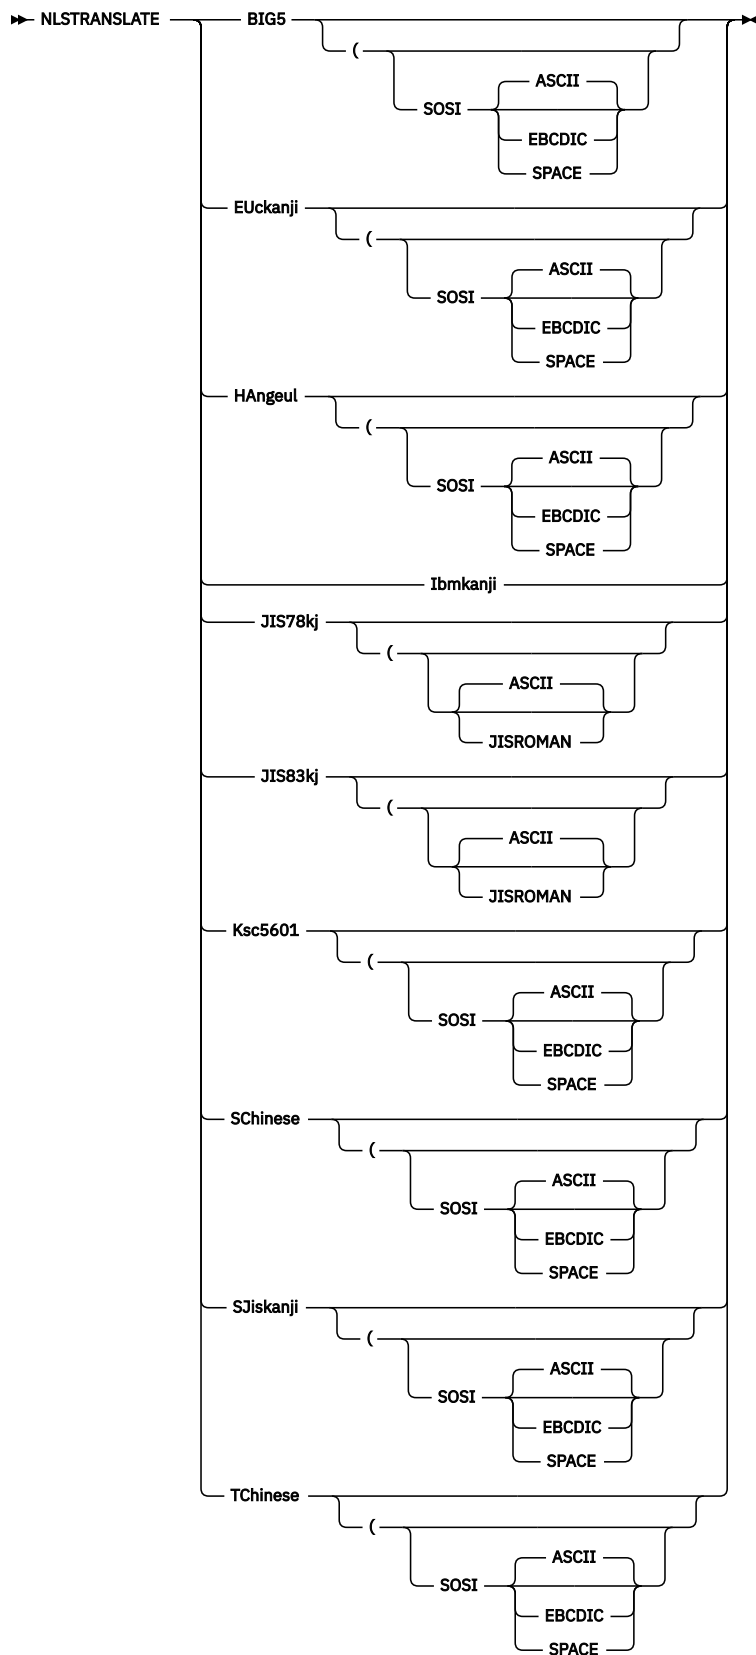

local_options

nje_options

Syntax

Parameters

name

The service name must be one to eight characters in length. This value is case sensitive.

Restriction: Only characters permitted in MVS data set names are valid.

PRINTER

Specifies the service is to a printer. For LOCAL or NJE devices, the JES spool file created is allocated with RECFM=UM and machine carriage control is written in column 1 of the file. For filter 1, this is always a single space ('09'X). For other filters, it is determined from the data received.

RECFMU

Specifies the service is to a printer. For LOCAL or NJE devices, the JES spool file created is allocated with RECFM=U and carriage control characters are not added to the beginning of each line. The JES spool file is like PRINTER, but carriage control is not added.

RECFMUA

Specifies the service is to a printer. For LOCAL or NJE devices, the JES spool file created is allocated with RECFM=UA. The carriage control (CC) character is taken from the first column of user data after any LPD processing.

Restriction: Only filter 1 should be allowed with this device type.

Specify filters 1 in the SERVICE statement so LPD does not print jobs requesting other filter options. The LPD trace would show message EZA0801I for these aborted jobs.

PUNCH

Specifies the service is to a punch device. For LOCAL or NJE devices, the JES spool file created is allocated with RECFM=UM and machine carriage control is written in column 1 of the file.

NONE

Specifies that the service is not currently in use.

LOCAL

Specifies that the data sets sent to a service are written to the local MVS printer or punch.

CLASS=class

The SYSOUT class. The default is A for printers and B for punches.

OUTPUT=name

Specifies the name of an OUTPUT DD statement that contains additional spool parameters.

NJE

Specifies that the data sets sent to a service are delivered to the NJE system.

CLASS=class

The SYSOUT class. The default is A for printers and B for punches.

DEST=node

The name of the NJE node. The default is the local node.

IDENTIFIER=user_id

The device user ID. The default is SYSTEM.

PRIORITY=priority

Specifies the transmission priority. The default is 50.

OUTPUT=name

Specifies the name of an OUTPUT DD statement that contains additional spool parameters.

REMOTE

Specifies that data sets (jobs) sent to this service queue are forwarded immediately to the specified remote printer. If the remote printer is not available, the job is discarded.

Guideline: If discarded jobs are a problem, consider sending the jobs directly to the final LPD with LPR, instead of using the MVS LPD as an intermediate router.

printer@host

The destination printer at a specified Internet host. This can be an Internet name or an IP address.

EPORT

For the *Remote* service, when LPR ports 721-731 are in use, LPD tries to use non-reserved ports in the 732 - 1 023 range. The default action, when EPORT is not specified, is to only use the ports 721 - 731 defined by RFC 1179.

EXIT

Specifies any program to be executed before closing, but after allocating and opening, an output data set.

START

Specifies that the program is invoked after allocating and opening the output data set, but before anything is written to the data set. This parameter is mutually exclusive of the END parameter.

END

Specifies that the program is invoked just before closing the output data set. This parameter is mutually exclusive of the START parameter.

program

Name of the program to be invoked. See z/OS Communications Server: IP Configuration Guide for information about using the default LPBANNER or creating your own banner program. The library containing the program should be in the system's link list (LNKLSTxx), or a STEPLIB definition can be used if the library is APF authorized.

FAILEDJOB

Specifies whether a notice of failed jobs should be mailed to users or a job is discarded without notice.

MAIL

Specifies that notices of failed jobs are mailed to users.

Requirement: To use the MAIL parameter, you must also specify the SMTP parameter. Messages are logged in the LPD joblog, showing the information sent to SMTP.

DISCARD

Specifies that failed jobs are discarded without notice.

FILTERS

The control file received by LPD specifies the filter actually used. LPD formatting for each possible filter is described here. When IASf is specified, any filter l received is treated as filter f, described as follows:

f

Print formatted file paginates the data set at the size of the page given. It also truncates lines if they exceed a maximum length.

This filter causes the data file to be printed as a plain text file, providing page breaks as necessary.

Restriction: Only the following ASCII control characters are honored:

- HT
- CR
- FF
- LF
- VT
- BS

They are removed from the data stream (not printed) and changed into equivalent spacing and machine carriage control. Any ASCII code that translates to an EBCDIC NL is also honored. However, standard ASCII tables do not have an NL (new line) control character.

JES writers start each job on a new page. Therefore, LPD suppresses any FF (form feed) at the beginning of the data to avoid an extra page eject before the user's data set is printed.

l

Print file leaving control characters does not insert pagination but does truncate lines. All lines are single spaced.

This filter causes the specified data file to be printed without filtering out control characters (except LF, which is used to determine line endings when converting to a JES record oriented spool file). Other ASCII control characters are translated to EBCDIC and printed as text. They are *not*

converted to equivalent machine carriage control. Use filter `f` to control codes like FF and HT to be honored.

Filter `l` can behave like filter `IASf` if you specify `IASf` instead of `l`. See `IASf` below.

IASf

***p* - Print file with 'pr' format**

Paginates data set, adding titles, the date, and page numbers as well as providing line truncation.

This filter causes the data file to be printed with a heading, page numbers, and pagination. Page breaks are determined by the `PAGESIZE` configuration on the `SERVICE` statement, or by ASCII FF (form feed) control characters in the data stream. `PAGESIZE` includes the title lines printed.

JES writers start each job on a new page. Therefore, LPD suppresses any FF (form feed) at the beginning of the data to avoid an extra page eject before the user's data set is printed.

***r* - File to print with FORTRAN carriage control**

Prints the data set, interpreting the first column of each line as a FORTRAN carriage control. The FORTRAN controls are removed from the data stream and translated into equivalent machine carriage control. LPD honors " ", "1", "0", "+", and "-". Other values in column 1 cause single spacing. LPD also truncates lines if they exceed `LINESIZE`. Page breaks are determined by the `PAGESIZE` configuration as well as the Fortran controls in column 1.

LINESIZE

Specifies the line length used by the filters when they truncate lines. This statement only applies to services that are designated as either `LOCAL` or `NJE` on `PAGESIZE` (for example, 100 000).

length

The number of characters in a line on a page. Lines longer than this number are truncated. The default is 132.

PAGESIZE

Specifies the page length used by the filters when they paginate.

This statement only applies to services that are designated as either `LOCAL` or `NJE`.

lines

The number of lines on a page. The default is 60.

RACF

Controls which users print data sets on this service.

SMTP

Specifies the `CSSMTP` external writer name, `CLASS`, and `DEST` options for sending failed jobs notices. For additional information, see the description of the `FAILEDJOB MAIL` parameter.

server_name

Specifies the name of the `CSSMTP` external writer name. If this statement is omitted, the default is `SMTP`.

CLASS=class

The `SYSOUT` class. The default is `A` for printers and `B` for punches.

DEST=node

The `NJE` node to which `SMTP` messages should be sent.

TRANSLATETABLE

Specifies the translation table in the *name*.`TCPXLBIN` data set to be used by the client. `XLATETABLE` is a synonym for this parameter.

name

Specifies the SBCS translate table to be used when a client selects this `SERVICE`. The *name* parameter is preceded by either the job name or the *hlq* and followed by `TCPXLBIN` to form the data set name of the translate table (jobname.name.`TCPXLBIN` or *hlq*.name.`TCPXLBIN`). If both data sets exist, which one to use is determined by a search order hierarchy.

See [z/OS Communications Server: IP Configuration Guide](#) for more information about search order hierarchy, loading, and customizing of SBCS translation tables.

Tip: XLatetable is a synonym for this option.

XLATETABLE

Specifies the translation table in the *name*.TCPXLBIN data set to be used by the client. TRANSLATETABLE is a synonym for this parameter.

name

Specifies the SBCS translate table to be used when a client selects this SERVICE. The name parameter is preceded by either the job name or the *hlq* and followed by TCPXLBIN to form the data set name of the translate table (jobname.name.TCPXLBIN or *hlq*.name.TCPXLBIN). If both data sets exist, which one to use is determined by a search order hierarchy.

See [z/OS Communications Server: IP Configuration Guide](#) for more information about search order hierarchy, loading, and customizing of SBCS translation tables.

Tip: TRANslatetable is a synonym for this option.

NLSTRANSULATE

Specifies the DBCS translation type to be used when a client selects the named SERVICE.

BIG5

Select the translation type from Big-5 P-C DBCS codes to Traditional Chinese host codes.

EUckanji

Select the translation type from Japanese EUC DBCS codes to Japanese host codes.

HAngeul

Select the translation type from Korean PC DBCS codes to Korean host codes.

Ibmkanji

This option causes no conversion to be performed; in other words, data is sent to a printer without translation. Ibmkanji can be used for sending data in EBCDIC. If you select this option, be sure other printers on the same network are all configured with Ibmkanji.

JIS78kj

Select the translation type from JIS 1978 DBCS codes to Japanese host codes. The Escape Sequence, ESC 2/4 4/0, is used to express JIS X0208 1978.

JIS83kj

Select the translation type from JIS 1983 DBCS codes to Japanese host codes. The Escape Sequence, ESC 2/4 4/2, is used to express JIS X0208 1983.

Ksc5601

Select the translation type from IBM KS DBCS codes to Korean host codes.

SChinese

Select the translation type from Simplified PC Chinese DBCS codes to Simplified Chinese host codes.

SJiskanji

Select the translation type from Shift JIS DBCS codes to Japanese host codes.

TChinese

Select the translation type from Traditional Chinese 5550 PC DBCS codes to Traditional Chinese host codes.

SOSI

Shift-Out and Shift-In characters X'1E' and X'1F' are used in data to delimit DBCS strings.

SOSI ASCII

Shift-Out and Shift-In characters X'1E' and X'1F' are used in data to delimit DBCS strings.

SOSI EBCDIC

Shift-Out and Shift-In characters X'0E' and X'0F' are used in data to delimit DBCS strings.

SOSI SPACE

Shift-Out and Shift-In characters X'20' and X'20' are used in data to delimit DBCS strings.

ASCII (with JIS78KJ and JIS83KJ only)

The ASCII Escape Sequence, ESC 2/8 4/2, is used in data to express SBCS strings.

JISROMAN (with JIS78KJ and JIS83KJ only)

The JISROMAN Escape Sequence, ESC 2/8 4/10, is used in data to express SBCS strings.

Examples

- PRINTER and PUNCH definitions

The sample configuration data set SEZAINST(LPDDATA) provides examples of SERVICE statements for LOCAL, REMOTE, and NJE printers and a LOCAL punch.

- EXIT Parameter

To make the LPBANNER program print a page at the beginning of the printed output, use the EXIT START parameter within a SERVICE statement, as shown here:

```
SERVICE locprt1 PRINTER
LOCAL
FILTERS f l p r
LINE SIZE 132
PAGE SIZE 60
EXIT START LPBANNER
```

To make the LPBANNER program print a page at the end of the printed output, use the EXIT END parameter within a SERVICE statement, as shown here:

```
SERVICE locprt1 PRINTER
LOCAL
FILTERS f l p r
LINE SIZE 132
PAGE SIZE 60
EXIT END LPBANNER
```

See RFC 1179, Section 7.5 Line Printer Daemon Protocol, for more information about the LPD user exit.

Usage notes

- For remote printers, observe these guidelines:

Remote printers do not require specifications for EXIT, FAILEDJOB, FILTERS, LINE SIZE, PAGE SIZE, RACF, SMTP, and translation tables. These are defined on the remote system.

The LPR command must be specified with the printer name as it is specified on the SERVICE statement. The HOST parameter can HOSTNAME or the IP address of the host the LPD is running on, *not* the printer name and IP address of the remote printer.

```
LPR fn (p pebprt h LPDSrvHostName
```

This is required if you want to send data to the remote printer using this LPD.

- With RACF, observe these guidelines:

In order to print data sets on a printer that has RACF specified, the user must use the JOB option with a valid password on the LPR command.

If the RACF keyword is specified for the service and a valid password is not supplied, the job sent to that service fails.

If a printer is defined as RACF for a local service on one system and as an NJE service on other systems, then you must specify the RACF keyword on the SERVICE statement on each of the systems where this service is defined.

- For SMTP, observe these guidelines:

- SMTP is used in conjunction with the FAILEDJOB statement. If the MAIL keyword is used on the FAILEDJOB statement, then the SMTP *server_name* should be set to the name of the SMTP server and an optional CLASS and Destination NJE node.

- If the job name is not specified on the corresponding LPR operation, JOB is the data set name that was printed by LPD.
- If CLASS is omitted on the LPR operation, it contains the sending system's host name.
- The following parameters are passed to the *program* but not defined in the EXIT statement.

A pointer to an open DCB for the JES spool file. The DCB is (DSORG=PS, MACRF=PL, RECFM=UM) for SERVICE printer or SERVICE PUNCH devices. THE DCB is (DSORG=PS, MACRF=PL, RECFM=U) for SERVICE RECFMU devices.

Syntax

Parameters

dasdname

The generic name of a group of DASD.

VOLUME statement

Use the VOLUME statement to specify the specific DASD volume where LPD writes its temporary data sets while the transfer of data from an LPR client occurs.

Syntax

```
➤ VOLUME — dasdname ➤
```

Parameters

dasdname

The volume serial number. The value specified for *name* is case sensitive.

Examples

To set the volume name for new data set to WRKLB4, code the following:

```
VOLUME WRKLB4
```

Chapter 21. PORTMAP and UNIX PORTMAP

This topic contains the following information:

- “PORTMAP cataloged procedure (PORTPROC)” on page 1235
- “UNIX PORTMAP cataloged procedure (OPORTRPC)” on page 1235

PORTMAP cataloged procedure (PORTPROC)

This following sample shows the PORTMAP cataloged procedure (PORTPROC).

```
//PORTMAP PROC MODULE=PORTMAP,PARMS=''

Figure 45. UNIX PORTMAP cataloged procedure (OPORTRPC)

Chapter 22. RPCBIND

This topic includes the following information:

- “RPCBIND cataloged procedure” on page 1237

RPCBIND cataloged procedure

The following sample shows the RPCBIND cataloged procedure.

```
//RPCBIND PROC
//*
//* TCP/IP FOR MVS
//* SMP/E DISTRIBUTION NAME: EZARBBND
//*
//* 5694-A01 (C) COPYRIGHT IBM CORP. 2007
//* LICENSED MATERIALS - PROPERTY OF IBM
//* THIS PRODUCT CONTAINS "RESTRICTED MATERIALS OF IBM"
//* ALL RIGHTS RESERVED.
//* US GOVERNMENT USERS RESTRICTED RIGHTS -
//* USE, DUPLICATION OR DISCLOSURE RESTRICTED BY
//* GSA ADP SCHEDULE CONTRACT WITH IBM CORP.
//* SEE IBM COPYRIGHT INSTRUCTIONS.
//*
//* FUNCTION: UNIX SYSTEM SERVICES RPCBIND SERVER MAIN PROCESS
//*
//RPCBIND EXEC PGM=RPCBIND,REGION=4096K,TIME=1440,
// PARM=('ENVAR("TZ=EST5EDT")/-d1')
//*
//STDOUT DD SYSOUT=*
//STDERR DD SYSOUT=*
//SYSOUT DD SYSOUT=*
//SYSPRINT DD SYSOUT=*
// PEND
```

Figure 46. Sample RPCBIND

You can specify the following options when starting rpcbind:

- For debug options, you can specify the following -d options to cause rpcbind to send trace information to the daemon facility of syslogd:
 - df**
Sends non-XDR flow information to syslogd.
 - dl**
Sends log information of all RPC procedures called to syslogd.
 - dx**
Sends XDR information to syslogd.
- The -i option enables you to specify the directory where the pid file should be written:
Rule: The pid filename is always rpcbind.pid. If -i is not specified, the rpcbind process ID is written to /etc/rpcbind.pid.
- The -n option enables you to direct rpcbind to run in a nonswappable environment. A process might need to run non-swappable to ensure it is available during periods of high CPU usage. However, a nonswappable process might convert real storage in the system to preferred storage. Because preferred storage cannot be configured offline, running rpcbind in a non-swappable state can reduce your installation's ability to reconfigure storage in the future.

If you do specify the -n option, ensure that the user ID associated with rpcbind has at least READ access to the resource BPX.STOR.SWAP in the FACILITY class.

The default is to start rpcbind as swappable.

- The -s option specifies the number of statistics entries per binding protocol that rpcbind maintains. The allowable range is 113 - 500. Statistics maintained by the rpcbind server are used to reply to the RPCBPROC_GETSTAT request. See RFC 1833 for more information about statistics maintained by the rpcbind server.

Result: Rpcbind calculates the number of pages needed to store statistics for the value specified and obtains that number of pages of shared memory for statistics. Thus, rpcbind rounds up the number of statistics entries it tracks to fully use the shared memory.

Tip: Rpcbind does not start unless it can obtain sufficient shared memory to maintain statistics for the number of entries specified. Configure the number of pages of shared memory available to z/OS with the IPCSHMMPAGES parameter in the BPXPRMxx member of SYS1.PARMLIB.

- To display help information, specify the -? option.

Chapter 23. NCS Interface

This topic contains the following information:

- “NRGLBD cataloged procedure (NRGLBD)” on page 1239
- “LLBD cataloged procedure (LLBD)” on page 1239

NRGLBD cataloged procedure (NRGLBD)

Update the NRGLBD cataloged procedure by copying the sample provided in SEZAINST(NRGLBD) to your system or recognized PROCLIB and modifying it to suit your local conditions.

Following is the sample NRGLBD cataloged procedure:

```
//NRGLBD  PROC MODULE=NRGLBD,PARMS=' '
//*
//*
//*      z/OS Communications Server
//*      SMP/E Distribution Name: EZAEB02D
//*
//* Copyright:   Licensed Materials - Property of IBM
//*              "Restricted Materials of IBM"
//*              5647-A01
//*              (C) Copyright IBM Corp. 1992, 2001
//*              US Government Users Restricted Rights -
//*              Use, duplication or disclosure restricted by
//*              GSA ADP Schedule Contract with IBM Corp.
//*
//* Status:      CSV1R2
//*
//NRGLBD  EXEC PGM=&MODULE,
//          PARM=&PARMS',REGION=4096K,TIME=1440
//*
//*      The C runtime libraries should be in the system's link list
//*      or add them to the STEPLIB definition here.  If you add
//*      them to STEPLIB, they must be APF authorized.  Change
//*      the name as appropriate for your installation.
//*
//STEPLIB DD DSN=TCPIP.SEZATCP,DISP=SHR
//SYSPRINT DD SYSOUT=*
//SYSOUT  DD SYSOUT=*
//OUTPUT  DD SYSOUT=*
//SYSIN   DD DUMMY
//*
//*      The SYSDUMP DD statement will cause MVS to provide
//*      an IPCS readable dump for ABENDs.
//*SYSDUMP DD DISP=SHR,DSN=your.dump.data.set
//*
//*      SYSTCPD explicitly identifies which data set is to be
//*      used to obtain the parameters defined by TCPIP.DATA
//*      when no GLOBALTCIPDATA statement is configured.
//*      See the IP Configuration Guide for information on
//*      the TCPIP.DATA search order.
//*      The data set can be any sequential data set or a member of
//*      a partitioned data set (PDS).
//SYSTCPD DD DSN=TCPIP.SEZAINST(TCPDATA),DISP=SHR
```

Figure 47. NRGLBD cataloged procedure

LLBD cataloged procedure (LLBD)

Update the LLBD cataloged procedure by copying the sample provided in SEZAINST(LLBD) to your system or recognized PROCLIB and modifying it to suit your local conditions.

Following is the sample LLBD cataloged procedure:

```

//LLBD      PROC MODULE=LLBD,PARMS=''
//*
//*          z/OS Communications Server
//*          SMP/E Distribution Name: SEZAINST(LLBD)
//*
//* Copyright:   Licensed Materials - Property of IBM
//*              "Restricted Materials of IBM"
//*              5647-A01
//*              (C) Copyright IBM Corp. 1992, 2001
//*              US Government Users Restricted Rights -
//*              Use, duplication or disclosure restricted by
//*              GSA ADP Schedule Contract with IBM Corp.
//*
//* Status:      CSV1R2
//*
//LLBD      EXEC PGM=&MODULE,
//          PARM=&PARMS',REGION=4096K,TIME=1440
//*
//*          The C runtime libraries should be in the system's link list
//*          or add them to the STEPLIB definition here. If you add
//*          them to STEPLIB, they must be APF authorized. Change
//*          the name as appropriate for your installation.
//*
//STEPLIB   DD DSN=TCPIP.SEZATCP,DISP=SHR
//SYSOUT    DD SYSOUT=*
//SYSPRINT  DD SYSOUT=*
//OUTPUT    DD SYSOUT=*
//*
//*          The SYSDUMP DD statement will cause MVS to provide
//*          an IPCS readable dump for ABENDs.
//*SYSDUMP   DD DISP=SHR,DSN=your.dump.data.set
//SYSIN     DD DUMMY
//*
//*          SYSTCPD explicitly identifies which data set is to be
//*          used to obtain the parameters defined by TCPIP.DATA
//*          when no GLOBALTCPIPDATA statement is configured.
//*          See the IP Configuration Guide for information on
//*          the TCPIP.DATA search order.
//*          The data set can be any sequential data set or a member of
//*          a partitioned data set (PDS).
//SYSTCPD   DD DISP=SHR,DSN=TCPIP.SEZAINST(TCPDATA)

```

Figure 48. LLBD cataloged procedure (LLBD)

Chapter 24. Communications Server SMTP application

The Communications Server SMTP (CSSMTP) application sends mail messages from a JES spool data set to an SMTP server.

For additional overview and configuration information about CSSMTP, see the information about the [Configuring the CSSMTP application in z/OS Communications Server: IP Configuration Guide](#).

This topic contains the following information:

- [“General syntax rules for CSSMTP” on page 1241](#)
- [“Starting CSSMTP” on page 1242](#)
- [“CSSMTP sample started procedure” on page 1244](#)
- [“CSSMTP configuration statements” on page 1245](#)
- [“CSSMTP environment variables” on page 1273](#)
- [“CSSMTP user exit version 3 and version 4” on page 1275](#)

General syntax rules for CSSMTP

The following list shows the general syntax rules for CSSMTP:

- Specify CSSMTP configuration files using the code page set in the environment variable `CSSMTP_CODEPAGE_CONFIG` or use default value `IBM-1047` for EBCDIC.
- Each statement must have a corresponding value and must be separated from its value by one or more blank spaces.
- Only one attribute and its value can be specified per line.
- Text beyond the specified attribute and value is ignored.
- If the first non-blank character on a line begins with the number sign (#), then the rest of the line is treated as a comment and is ignored.
- Characters that appear in statements must be printable characters, unless otherwise noted. The character set is limited to the 26 alphabetic characters (uppercase and lowercase), the 10 numeric digits, and the following 18 special characters:

- plus (+)
- asterisk (*)
- slash (/)
- comma (,)
- period (.)
- ampersand (&)
- left and right parentheses [()]
- straight single quote (')
- hyphen (-)
- equal (=)
- colon (:)
- straight double quote (")
- percent (%)
- less than (<)
- greater than (>)
- question mark (?)
- semicolon (;)

The following situations are exceptions to these rules:

- The MailAdministrator statement does not restrict any special characters
- ReportMailFrom statement does not restrict any special characters
- The ExtWrtName statement allows only the following special characters:
 - dollar sign (\$)
 - number sign (#)
 - at sign (@)
- Statements that are allowed only once must be specified only once. When a single statement is repeated, a warning message is written to the log file, and the last instance of the statement is used.
- Parameters that are allowed only once must be specified only once. If a single parameter is repeated, then the last instance of the parameter value is used.
- Specify multiple type statements and attributes based on the maximum allowed. When a statement or attribute is repeated more than the maximum number allowed, a warning message is written to the log file. The first instances, up to the maximum number of instances that are allowed, are used.
- Statements that contain braces ({ }) must specify the braces on separate lines. For example:

```
TargetServer
{
    TargetIp    9.66.103.222
}
```

- Any IP address reference can be either an IPv4 format or IPv6 format IP address when the stack is running in IPv6-enabled mode.
- At least one valid IP address or target name is required for the configuration to be valid. See [“TargetServer statement” on page 1264](#) for details about configuration.
- Any warning that is detected during parsing causes messages to be written to the log and a single warning message to be written to the console. The new configuration is installed.
- You can use static system symbols in CSSMTP configuration file statements.

Results:

- If a configuration error is detected during startup, then CSSMTP writes an error message to the log and console, and exits.
- If a configuration error is detected during a dynamic refresh, then the entire refresh is rejected, an error message is written to the log and console, and CSSMTP continues running with the old configuration values.
- CSSMTP terminates in the following situations:
 - Start option errors are detected during initialization
 - Configuration file does not exist at initialization
 - Configuration file errors are detected during initialization
 - JES is not available during initialization
 - JES becomes unavailable while CSSMTP is processing the mail messages
 - The stop command is issued
 - The mail directory for extended retry becomes unusable

Starting CSSMTP

Use the S CSSMTP command on an MVS console or System Display and Search Facility (SDSF) to start CSSMTP.

Rules:

- You must start CSSMTP from a started procedure. A sample started procedure is included in member CSSMTP in SEZAINST. A configuration file is required. A sample CSSMTP configuration file is included in member CSSMTPCF in SEZAINST.
- Multiple instances of CSSMTP with different job names can be started with or without stack affinity. Each instance of CSSMTP that is running must be configured with a different external writer name. See “ExtWrtName statement” on page 1252 for more information.

The following options (in the started procedure) apply to CSSMTP:

-p | -P *tcipJobName*

The *tcipJobName* parameter is used in a common INET configuration to choose a socket stack for CSSMTP. It is also used for resolver functions. The environment variable `_BPXK_SETIBMOPT_TRANSPORT` can also specify the *tcipJobName*. The -p start option overrides the environment variable. If neither form is used to set the *tcipJobName*, then no affinity is used in a common INET configuration.

Results: In a Common INET configuration, there might be more than one TCP/IP stack. CSSMTP acts as a TCP/IP client. In this type of environment, you might want to associate CSSMTP with a specific stack, especially when there are multiple instances of CSSMTP to be started.

- The following list shows the priority for establishing TCPIP affinity for socket functions:
 1. Start option **-p** (CSSMTP sets affinity before any socket or resolver calls are made)
 2. Environment variable `_BPXK_SETIBMOPT_TRANSPORT`
 3. No affinity
- The following list shows the priority for establishing TCP/IP affinity for resolver functions:
 1. Application affinity.
 2. `_BPXK_SETIBMOPT_TRANSPORT`.

For resolver affinity information, see [z/OS Communications Server: IP Configuration Guide](#).

-f | -F

This start option indicates that CSSMTP performs a cold start and flushes any checkpoint records from the previous execution of CSSMTP. To use checkpointing, you must set the CHKPOINT DD statement in the started procedure. The default is to use the checkpoint records to restart JES spool files at their last known status.

Tip: Member CSSMTPVPL in SEZAINST is a sample job that you can use to allocate a VSAM linear data set that CSSMTP can use for checkpointing. Each instance of CSSMTP must have a unique checkpoint dataset. The checkpoint dataset cannot be shared between multiple instances of CSSMTP.

Result: If a valid CHKPOINT DD statement is not configured, checkpointing is not performed.

For resolver affinity, see [z/OS Communications Server: IP Configuration Guide](#).

If CSSMTP cannot successfully parse the start options, log output is written to stdout and the application exits.

If you want time values that are generated by CSSMTP to appear in local time, you must set the TZ environment variable. If you do not set the TZ environment variable, timestamps created by CSSMTP are in Universal Time Coordinated (UTC) by default.

Set the TZ and configuration code page environment variables in one of the following ways:

- Specify TZ using the ENVAR parameter on the PARM statement in the started procedure. For example, use the following code:

```
// PARM=('POSIX(ON) ALL31(ON)',
// 'ENVAR("CSSMTP_CODEPAGE_CONFIG=IBM-1047"',
// '"TZ=EST5EDT")/')
```

- Export the TZ and configuration code page environment variables in a file specified with the STDENV DD statement. For example, use the following code:

```
//STDENV DD PATH='/etc/cssmtp.env',PATHOPTS=(ORDONLY)
```

In the /etc/cssmtp.env file, use the following code:

```
TZ=EST5EDT
CSSMTP_CODEPAGE_CONFIG=IBM-1047
```

See [z/OS Language Environment Programming Guide](#) for more information about specifying runtime options and environment variables. See [z/OS UNIX System Services Command Reference](#) for details about setting the TZ environment variables.

CSSMTP sample started procedure

This topic contains a copy of the sample procedure.

```
//CSSMTP JOB JESLOG=(SPIN,'00:00'),MSGCLASS=A
//*
//* JESLOG=(SPIN,'00:00')
//* Spin the jeslog files once a day at midnight.
//* This closes out the current JES joblog and creates a new one.
//*
//* Use 'opt' to pass in parameters. Example: s cssmtp,opt='-f'
//CSSMTP PROC OPT=''
//*
//* IBM Communications Server for z/OS
//* SMP/E distribution name: EZAMLSAM
//*
//* Licensed Materials - Property of IBM
//* 5650-ZOS
//* Copyright IBM Corp. 2009, 2013
//* Status = CSV2R1
//*
//* Function: Sample procedure for running the
//* CSSMTP application
//*
//* This example shows no input parameter, but -p, -f or both
//* can be used here
//*
//CSSMTP EXEC PGM=CSSMTP,REGION=0K,TIME=NOLIMIT,
// PARM=('ENVAR("_CEE_ENVFILE_S=DD:STDENV")/&OPT')
//*
//* Environment variables:
//* - Provide environment variables to run with the desired
//* configuration. As an example, the data set or file specified by
//* STDENV could contain:
//*
//* TZ=EST5EDT
//* CSSMTP_CODEPAGE_CONFIG=IBM-1047
//*
//* If you want to include comments in the data set or
//* z/OS UNIX file, specify the _CEE_ENVFILE_COMMENT
//* environment variable as the first environment variable
//* in the data set or file. The value specified for
//* the _CEE_ENVFILE_COMMENT variable is the comment character.
//* For example, if you want to use the pound sign, #, as
//* the comment character, specify this as the first
//* statement:
//* _CEE_ENVFILE_COMMENT=#
//*
//STDENV DD PATH='/etc/cssmtp.env',PATHOPTS=(ORDONLY)
//*STDENV DD DSN=TCPIP.TCPPARMS(CSSMTPEV),DISP=SHR
//*
//*
//* - The CSSMTP requires a configuration file. If
//* DD statement not configured, then the default is
//* <jobname>.CSSMTP.CONF. The configuration file can be a
//* member of an MVS PDS(E), an MVS sequential file,
//* or a z/OS UNIX file.
//* See tcpip.SEZAINST(EZAMLCNF) for a sample configuration
//*
//CONFIG DD DSN=TCPIP.TCPPARMS(CSSMTP),DISP=SHR
//*CONFIG DD DSN=TCPIP.CONFIG.CSSMTP,DISP=SHR
//*CONFIG DD PATH='/etc/cssmtp.conf',PATHOPTS=(ORDONLY)
//*
//* - Output written to stdout and stderr goes to the data set or
```

```

/** file specified with or SYSOUT, respectively.
/** Normally, CSSMTP doesn't write output to stdout or stderr, but
/** instead, output is written to the log file, which is specified
/** by LOGFILE DD statement, and defaults to syslog
/** daemon. Severe startup errors, such as incorrect options
/** specified, or being unable to open the log file, log output
/** is instead written to stdout.
/**
/** - The logfile file can be a MVS sequential file, a z/OS UNIX file,
/** SYSOUT or syslog daemon. The default is syslog daemon.
/**
/** - If multiple CSSMTP are logging to the same log file, the user
/** should use different log files or SYSLOGD. Using the same
/** log file from different applications can produce unpredictable
/** results.
/**
/**LOGFILE DD PATH='/tmp/cssmtp.log',
/** PATHOPTS=(OWRONLY,OCREAT,OAPPEND),
/** PATHMODE=(SIRUSR,SIWUSR,SIRGRP,SIWGRP)
/**LOGFILE DD SYSOUT=*,
/** DCB=(RECFM=VB,LRECL=1028,BLKSIZE=3120)
/**LOGFILE DD DSN=USER140.CSSMTP.LOG2,DISP=(MOD,CATLG),
/** SPACE=(TRK,(10)),DCB=(RECFM=VB,LRECL=1028,BLKSIZE=3120)
/**
/** - Input/Output VSAM linear file that contains JES
/** checkpoint information. This is used if CSSMTP is not started
/** with -f.
/**
/** The Chkpoint file is a VSAM linear file. If not configured
/** then no checkpointing is done for JES spool files.
/** See the sample JCL in CSSMTPVL to allocate the checkpoint
/** data set.
/**
/**CHKPOINT DD DSN=TCPIP.CSSMTP.CHKPOINT,DISP=SHR
/**
/** - Output written to stdout and stderr goes to the data set or
/** file specified with SYSOUT, respectively.
/**SYSOUT DD SYSOUT=*
/**
/** - SYSTCPD explicitly identifies which data set is to be
/** used to obtain the parameters defined by TCPIP.DATA
/** when no GLOBALTCPIPDATA statement is configured.
/** See the IP Configuration Guide for information on
/** the TCPIP.DATA search order.
/** The data set can be any sequential data set or a member of
/** a partitioned data set (PDS).
/**
/**SYSTCPD DD DSN=TCPIP.SEZAINST(TCPDATA),DISP=SHR

Figure 49. CSSMTP application sample start procedure

CSSMTP configuration statements

Table 105 on page 1245 lists CSSMTP configuration file statements.

Table 105. CSSMTP configuration statements				
Configuration file statement	Default	Required or optional	Update allowed by modify refresh	Purpose
BadSpoolDisp	Hold	Optional	Yes	Specifies the action to be taken when errors are encountered while the JES spool file is being processed.

Table 105. CSSMTP configuration statements (continued)

Configuration file statement	Default	Required or optional	Update allowed by modify refresh	Purpose
ChkPointSizeLimit	64000	Optional	No	Specifies the number of concurrent mail messages for which checkpoint information is saved.
ExtendedRetry	<ul style="list-style-type: none"> • Age 5 • Interval 30 • MailDirectory /var/cssmtp/extwrtname/mail/ 	Optional	Yes (except MailDirectory)	Specifies the limits that CSSMTP uses when it attempts to resend mail messages that are not immediately deliverable after RetryLimit processing.
ExtWrtName	task job name	Optional	No	Specifies the external writer name that is used by CSSMTP for selection criteria when interfacing with the JES2 or JES3 subsystems.
Header	<ul style="list-style-type: none"> • Date Yes • UserInfo Yes 	Optional	Yes	Specifies the action to be taken when creating RFC 2822 mail headers.
JESJobSize	0 (unlimited)	Optional	Yes	Specifies the maximum data set size that is accepted from the JES spool file in thousands of bytes.
JESMsgSize	0 (unlimited)	Optional	Yes	Specifies the maximum mail message size that is accepted from a JES spool file, in thousands of bytes.

Table 105. CSSMTP configuration statements (continued)

Configuration file statement	Default	Required or optional	Update allowed by modify refresh	Purpose
JESSyntaxErrLimit	5	Optional	Yes	Specifies the maximum number of syntax errors that are acceptable in a JES spool file before the rest of the JES spool file processing is stopped.
LogLevel	7	Optional	Yes	Specifies the level of logging and tracing.
MailAdministrator	No e-mail address is configured to send a report.	Optional	Yes	Specifies an e-mail address to which CSSMTP delivers reports for certain errors. This statement can be specified up to four times in a configuration file to deliver reports to multiple administrators.
MailBoxCompatibility	Standard	Optional	Yes	Specifies the size of the mailbox. The standard length is 64.
MBCS	No	Optional	No	Specifies whether or not CSSMTP supports multi-byte character sets.
Options	<ul style="list-style-type: none"> • AtSign @ • DataLineTrunc No • NullTrnc No • TestMode No • TLSEhlo No • ReplaceSubjectAtsign Yes 	Optional	Yes (except TestMode)	CSSMTP options
Report	Sysout	Optional	Yes	Specifies the action to be taken when problems are reported with JES spool files.

Table 105. CSSMTP configuration statements (continued)

Configuration file statement	Default	Required or optional	Update allowed by modify refresh	Purpose
ReportMailFrom	No email address is configured to send a report	Optional	Yes	Specify a default mail sender to be used in the MAIL FROM field in reports when the REPORT statement specifies Admin.
ReportSysoutClass	Use the same class as the spool file	Optional	Yes	This provides the ability to specify the SYSOUT class for reports when the REPORT statement specifies Sysout.
RetryLimit	Interval 1 Count 5	Optional	Yes	Specifies the limits that CSSMTP uses when attempting to re-send mail messages that are not immediately deliverable.
SMF119	No SMF recording	Optional	Yes	Specifies the records to be written to SMF.
TargetServer	<ul style="list-style-type: none"> • AuthEntity (no default) • Charset ISO8859-1 • ConnectPort 25 • ConnectLimit 5 • MaxMsgSent 0 • MBCharset (no default) • MessageSize 524288 • Secure No <p>You must provide a value for TargetIP, TargetName, or TargetMx.</p>	Required	Yes	Specify one or multiple TargetServer statements to define target servers (resolved or configured IP addresses) and their connection attributes to which CSSMTP connects for sending mail.

Table 105. CSSMTP configuration statements (continued)

Configuration file statement	Default	Required or optional	Update allowed by modify refresh	Purpose
Timeout	<ul style="list-style-type: none"> AnyCmd 300 ConnectRetry 120 DataBlock 180 DATACmd 120 DataTerm 600 InitialMsg 300 MAILCmd 300 RCPTCmd 300 ConnectIdle 0 	Optional	Yes	Specifies the timeout values, in seconds, for the interaction between CSSMTP and a target server.
Translate	IBM-1047	Optional	No	Specifies the translation code page of the records read from the JES spool data set.
Undeliverable	ReturnToMailFrom Yes DeadLetterAction Store DeadLetterDirectory /var/cssmtp/extwrtname/deadletter/	Optional	Yes	Specifies the method to use for handling undeliverable mail.
UserExit	None	Optional	Yes	Controls whether this CSSMTP calls CSSMTP exit program provided by the customer to examine data being sent to CSSMTP from the JES spool data set.

BadSpoolDisp statement

Use the BadSpoolDisp statement to indicate to CSSMTP what to do with JES spool files when errors were encountered when processing the spool file. See the information about [Terms and concepts in z/OS Communications Server: IP Configuration Guide](#) for a description of bad spool file.

Syntax

Parameters

Delete

Specify that CSSMTP should delete the spool file.

Hold

Specify that CSSMTP should change the disposition of the spool file to HOLD so that CSSMTP cannot process it.

ChkPointSizeLimit statement

Use the ChkPointSizeLimit statement to specify the number of concurrent mail messages for which checkpoint information is saved. This saved information is used for a warm start so that CSSMTP does not reprocess the entire spool file during a restart. Checkpointing warm functions only when you are restarting CSSMTP with the same job name and external writer name.

Syntax

Parameters

limit

An integer value in the range 64 000 - 512 000 that represents the number of concurrent mail messages that can have checkpoint information saved. The default size is 64 000.

Tip: If the CHKPOINT data set is not allocated, this value is ignored.

Result: If an update to the ChkPointSizeLimit statement is detected during a dynamic refresh, CSSMTP continues to run using the previous ChkPointSizeLimit value and a warning message is written to the log and console.

ExtendedRetry statement

Use the ExtendedRetry statement to extend the retry processing that Communications Server SMTP (CSSMTP) uses when it attempts to resend mail messages that are not immediately deliverable. For basic information about extended retry, see the information about [Terms and concepts in z/OS Communications Server: IP Configuration Guide](#).

The RetryLimit statement defines the retry interval during which CSSMTP will try sending the mail messages again while the JES spool file is still available. When the long retry interval expires (the interval is the product of multiplying the COUNT and INTERVAL values), the mail messages are copied to a z/OS UNIX directory for extended retry processing and the JES spool file is released. When the extended retry interval expires, the mail messages become undeliverable.

After both the long retry interval and the extended retry interval retries have expired, the following actions occur when information about the mail sender's address is available:

1. CSSMTP uses the setting on the ReturnToMailFrom parameter in the UNDELIVERABLE statement to determine its next action.
2. CSSMTP attempts to send the undeliverable mail notifications to the originator of the mail message through the configured target servers. If CSSMTP cannot send the notification on the first try, the mail message becomes a dead letter (see [“UNDELIVERABLE statement”](#) on page 1271) and no retries will be made.

Guideline: If the ExtendedRetry statement is not defined in the configuration file, extended retry processing is inactive.

Tip: You can set the Interval parameter on the ExtendedRetry statement to 0 to bypass extended retry processing.

Syntax

➡ ExtendedRetry — Put Braces and Parameters on Separate Lines ➡

Put Braces and Parameters on Separate Lines

ExtendedRetry Parameters

Parameters

Age days

Indicates the number of days that CSSMTP attempts to resend mail messages after the extended term retry interval expires. The default value is 5 days. The value 0 means that an unlimited number of retry attempts will be made. The maximum value is 2147483647.

Interval minutes

Indicates the length of time, in minutes, that CSSMTP waits between subsequent attempts to resend mail messages. The default value is 30 minutes. The maximum value is 1440 minutes (one day).

If the Interval value is 0, no extended retry will be performed and a mail message becomes undeliverable if CSSMTP cannot deliver it to the target servers on the first try.

MailDirectory mailDirectory

The fully qualified directory name in the z/OS UNIX file system where CSSMTP stores the mail message when the Interval parameter is set to a nonzero value. Valid values are 1 - 512 characters in length and must begin with a slash (/) to define the fully qualified directory. The default mail directory is `/var/cssmtp/extWrtName/mail/`, where `extWrtName` is the name specified in the ExtWrtName statement.

Results:

- A slash is added to the end of the mail directory name if it is not present.
- If the mail directory does not exist it is created.

Guidelines:

- The user ID that CSSMTP starts under must have read/write access to this directory. If you are running multiple CSSMTP servers with extended retry enabled, each server should have its own directory and should not have access to the directories of other servers.
- Ensure that there is adequate space in the filesystem for extending retry processing. For example, if each mail message is an average of 8000 bytes in size and you expect to have 1000 mail messages to be tried again, then about 16 million bytes of file space is needed $[2 \text{ (files per mail message)} \times 8K \text{ (z/FS file allocation size)} \times 1000]$. Factor in the 75% threshold for message ESD1862I, then the file system should be about 22 million bytes in size (plus a margin of error).
- The size of the MailDirectory is the sum of all of the size of all the mail messages saved for extended retry at any one time.

Restrictions:

- If extended retry processing is activated, you must stop and restart CSSMTP in order to change the name of the mail directory.
- If CSSMTP is active, you cannot change the name of the mail directory and you cannot delete or change the files.
- The content of the files created by CSSMTP and stored in the mail directory cannot be modified.

Tip: You can configure your mail directory to be on a different z/OS UNIX file system than where you have configured your deadletter directory. By doing this, you can manage the resource better. For more information, see [“UNDELIVERABLE statement”](#) on page 1271.

ExtWrtName statement

Use the ExtWrtName statement to specify the external writer name used by Communications Server SMTP (CSSMTP) as selection criteria when CSSMTP is interfacing with the JES2 or JES3 subsystems.

Syntax

Parameters

wrtName

A string 1 - 8 characters in length that specifies the external writer name to be used by CSSMTP. This value can contain alphanumeric characters, as well as the special characters \$ # @. The default value is the CSSMTP job name. The writer name is not case sensitive.

Results:

- If an ExtWrtName value is not configured, CSSMTP sets this parameter value to CSSMTP job name.
- If an update to the ExtWrtName statement is detected during a dynamic refresh, CSSMTP continues to run using the previous ExtWrtName value and a warning message is written to the log and console.

Tip: The SMTPD job name should not be specified for CSSMTP external writer name if the SMTPD gateway is running on the same LPAR. The results are unpredictable.

Restrictions:

- Do not code INTRDR, STDWTR, or NJERDR because these names are reserved for JES.
- If the JES2 DESTDEF statement specifies NODENAME=REQUIRED, then the writer name specified in the ExtWrtName statement must be defined to JES2. You can dynamically define it to JES using the following command:

```
$ADD DESTID(xxxxxxxx),DEST=xxxxxxxx
```

where xxxxxxxx is the *wrtName* specified in the ExtWrtName statement. See [z/OS JES2 Initialization and Tuning Reference](#) for information about the DESTDEF statement. To permanently add the destination use the JES initialization DESTid statement:

```
DESTID(xxxxxxxx) DEST=xxxxxxxx
```

See [z/OS JES2 Initialization and Tuning Reference](#) for information about the DESTID JES2 statement. If JES2 DESTDEF specifies NODENAME=OPTIONAL then the writer name specified on ExtWrtName does not need to be specified.

- You cannot start multiple CSSMTP applications that use the same external writer name.

Header statement

Use the Header statement to change the behavior of CSSMTP when you create RFC 2822 mail headers. The mail headers are created when the JES spool file is processed. If the Header parameters are modified, mail headers that have been created are not altered.

Syntax

►► Header — Put Braces and Parameters on Separate Lines ◄◄

Put Braces and Parameters on Separate Lines

Header Parameters

Parameters

Date

Specifies whether CSSMTP adds the Date: header if the header is missing.

NO

The Date: header is not inserted into the mail message by CSSMTP.

YES

The Date: header is inserted into the mail message by CSSMTP. This is the default value.

UserInfo

Specifies whether user information is included in Mail headers that CSSMTP creates.

NO

User information is not inserted into the mail message by CSSMTP. This setting applies to the following information:

- If CSSMTP creates the Message-ID: header, the job name of the mail message of the JES spool file and the job identifier of the JES spool file are not included in the Message-ID: header.
- The CSSMTP JobName is inserted in the for field of the Received: header instead of the JES origin USER ID and the optional Notify USER ID.
- The job name of the mail message of the JES spool file and the job identifier of the JES spool file are not included in the Id field of the Received: header.

YES

User information is inserted into the mail message by CSSMTP. This is the default value.

JESJobSize statement

Use the JESJobSize statement to specify the maximum data set size that is accepted from the JES spool file, in thousands of bytes.

Tip: Set this value for the largest spool job expected and add enough room for future growth.

Syntax

Parameters

size

An integer value in the range 0 - 1,000,000 that represent the maximum data set size that is accepted from the JES spool file, in thousands of bytes. The default size is 0, which specifies an unlimited data set size.

Restriction: The JESJobSize value must be greater or equal to the JESMsgSize value.

JESMsgSize statement

Use the JESMsgSize statement to specify the maximum mail message size accepted from a JES spool file, in thousands of bytes.

Tip: Set this value for the largest mail message expected and add enough room for future growth.

Syntax

Parameters

size

An integer value in the range 0 - 1,000,000 that represents the maximum mail message size accepted from a JES spool file, in thousands of bytes. The default size is 0, which specifies an unlimited data set size.

Restriction: The JESMsgSize value must be less than or equal to the JESJobSize value.

JESSyntaxErrLimit statement

Use the JESSyntaxErrLimit statement to specify the maximum number of syntax errors that are acceptable in a JES spool file.

Syntax

Parameters

count

An integer in the range 0 - 999 that represents the maximum number of syntax errors that are acceptable in a JES spool file. The default value is 5. The value 0 indicates that an unlimited number

of syntax errors is acceptable. If you set a high or unlimited value on this statement, then a waste of system resources such as CPU use can occur when the JES spool file contains many errors.

Tip: Syntax errors in the RCPT commands are not counted against the JESSyntaxErrLimit statement. Instead, a syntax error in a RCPT command is treated as an undeliverable mail message, if the rest of the SMTP commands are valid. Use the [“UNDELIVERABLE statement” on page 1271](#) to control the handling of undeliverable mail.

LogLevel statement

Use the LogLevel statement to specify the level of logging and tracing.

Syntax

Parameters

level

Specifies the log *level* . The *level* value represents a particular log level or combination of debug levels. Possible values are:

0

No messages are logged.

1

Error-level messages are logged.

2

Warning-level messages are logged.

4

Event-level messages are logged.

8

Information-level messages are logged.

16

JES-level messages are logged. This value traces Communications Server SMTP (CSSMTP) commands and command syntax parser replies between the JES spool file and CSSMTP.

32

Network-level messages are logged. This traces CSSMTP commands and remote SMTP server replies between CSSMTP and the TCP/IP network.

64

Debug-level messages are logged. These messages are internal debug messages intended for development and IBM service use only.

128

Trace-level messages are logged. These messages are function entry and exit traces that show the path through the code. This level is intended for development and IBM service use only.

Guideline: To log a combination of log levels, add the log level numbers and specify the resulting value. During the initialization phase of the application the log level is set to 127 to capture any initialization problems. When initialization is complete, then the log level value is set to what is coded on this statement. The default log level is 7, which captures all error, warning, and event messages after the initialization is complete.

MailAdministrator statement

Use the MailAdministrator statement to specify an e-mail addresses with the format *userid@host.domain* (mailbox) to which Communications Server SMTP (CSSMTP) delivers error reports. See the information about [Terms and concepts in z/OS Communications Server: IP Configuration Guide](#) for a description of mail administrator. Error reports are generated by CSSMTP when a problem is detected while processing a spool file from the JES subsystem (see the [“REPORT statement” on page 1260](#)).

Results:

- Only the first four MailAdministrator statements are used. If more than four MailAdministrator statements are configured, CSSMTP issues a warning message to the console and log.
- When configured (see the [“REPORT statement” on page 1260](#)), a report is sent to each mail administrator for each spool file that contains errors. This report is in the form of one e-mail with multiple recipients.
- When a MODIFY REFRESH command is issued and the order of the MailAdministrator statements or any of the mail addresses has changed, the configuration is updated.

Syntax

Parameters

mailbox

The mail administrator's e-mail address to which the CSSMTP delivers error reports. There is no default value

Restrictions:

- Duplicate mailbox names are not allowed.
- The *mailbox* value is case sensitive.
- The *mailbox* value must be defined as *userid@host.domain* for the mail address. The *userid* value can be 1 - 64 characters in length. The *host.domain* value can be 1 - 255 characters in length.

MailBoxCompatibility statement

Use the MailBoxCompatibility statement to specify the maximum mailbox length. The standard maximum mailbox length is 64. You can specify whether the mailbox should be Standard or Long.

Syntax

Parameters

Standard

Indicates that the maximum mailbox length is 64, which is the standard maximum length.

Long

Indicates that the maximum mailbox length is 256.

Results:

- The MailBoxCompatibility value can be either Standard or Long.
- If you specify the MailBoxCompatibility value as Standard, the maximum mailbox length is 64. If you specify the MailBoxCompatibility value as Long, the maximum mailbox length is 256.

MBCS statement

Use the MBCS statement to specify whether or not CSSMTP supports multi-byte character sets.

Syntax

Parameters

MBCS

Specifies whether CSSMTP supports multi-byte character sets.

NO

Multi-byte character sets are not supported. This is the default value.

YES

Multi-byte character sets are supported.

Results: If an update to the MBCS statement is detected during a dynamic refresh, CSSMTP continues to use the old MBCS value and a warning message is written to the log and the console.

Restrictions:

- If MBCS is specified as NO:
 - The TRANSLATE statement must specify a single byte code page.
 - The MBCharset statement, if specified, will be ignored.
- If MBCS is specified as YES:
 - The TRANSLATE statement must specify a multi-byte code page.
 - The MBCharset statement must be specified for each TargetServer, and it must be a multi-byte code page.

Usage notes: When migrating from the SMTP server, the following table contains suggestions for the TRANSLATE and MBCharset code pages that correspond to the SMTP server DBCS statement. The TRANSLATE code page must be the code page of the mail file on the JES spool, and the MBCharset code page must be the code page in which the TargetServer expects to receive the mail.

Table 106. TRANSLATE and MBCharset code pages that correspond to the SMTP server DBCS statement		
SMTP DBCS value	TRANSLATE value	MBCharset value
JIS78KJ ASCII	IBM-939	IBM-5055
JIS78KJ JISROMAN	IBM-930	IBM-5053
JIS83KJ ASCII	IBM-939	IBM-5054
JIS83KJ JISROMAN	IBM-930	IBM-5052
BIG5	IBM-937	IBM-950
EUCKANJI	IBM-930	IBM-eucJP

Table 106. TRANSLATE and MBCharset code pages that correspond to the SMTP server DBCS statement (continued)

SMTP DBCS value	TRANSLATE value	MBCharset value
KSC5601	IBM-933	IBM-949
SCHINESE	IBM-935	IBM-1381
SJISKANJI	IBM-930	IBM-943
TCHINESE	IBM-937	IBM-948

Restriction: CSSMTP does not support the IBMKANJI value from the SMTP DBCS statement.

Options statement

Use the Options statement to change the processing behavior of CSSMTP.

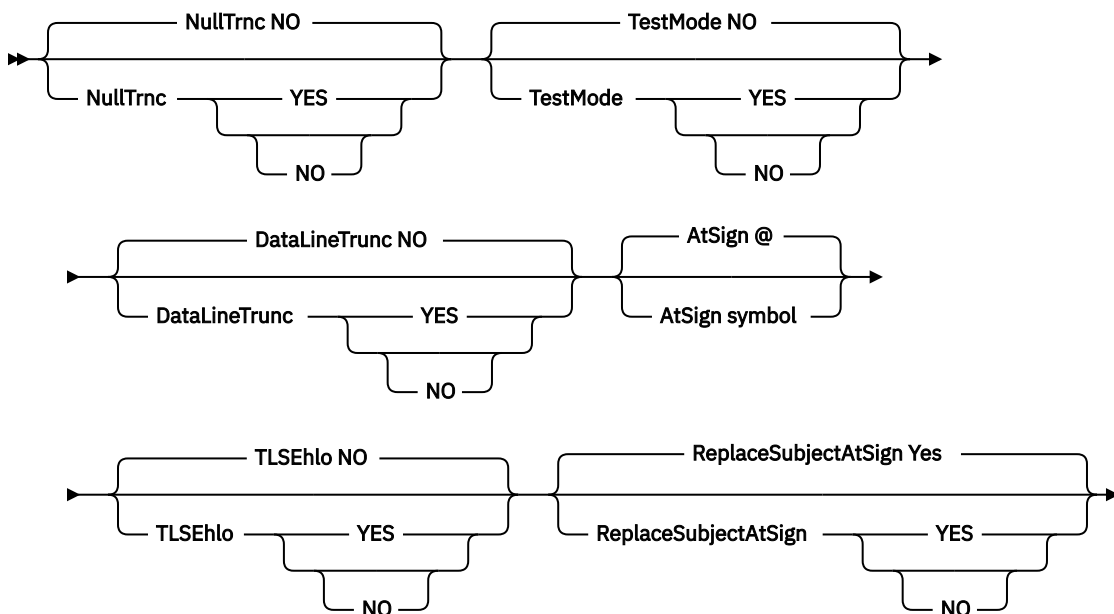

Syntax

Options — Put Braces and Parameters on Separate Lines

Put Braces and Parameters on Separate Lines

Options Parameters

Parameters

NullTrnc

Specifies whether the trailing null characters are stripped from mail command records. The mail command records include EHLO, HELO, MAIL, RCPT, DATA, and STARTTLS.

NO

The trailing null characters are not stripped from the mail command records by CSSMTP. This is the default value.

YES

The trailing null characters are stripped from the mail command records by CSSMTP.

TestMode

Indicates whether CSSMTP runs in test mode and does not deliver mail messages.

NO

Indicates that CSSMTP runs as a normal mail server and processes and delivers mail messages. This is the default value.

YES

Indicates that CSSMTP runs in compatibility test mode. CSSMTP processes mail messages from the spool file but does not deliver them. After the processing completes, mail messages are discarded instead of delivered or put into retry modes. In this mode, the only output that mail messages produce is error messages in the error report if any errors are encountered.

Result: If TestMode is set to Yes and no errors are found in a spool file, CSSMTP deletes the file when it completes processing. If errors are found, CSSMTP handles the spool files according to the setting of the BADSPOOLDISP configuration statement.

Guideline: When TestMode is set to Yes, ensure that the REPORT statement is coded with a valid destination for the error report; otherwise, warning message EZD1841I is issued.

Restriction: TestMode cannot be dynamically changed. You must stop and restart CSSMTP to change its value.

DataLineTrunc

Indicates what CSSMTP does when a message data line is too long. RFC 2821 specifies a maximum message data line length of 1000 bytes, including the CR/LF characters.

Guideline: This parameter is provided for compatibility with the SMTPD daemon. Use this parameter only when you migrate SMTPD to CSSMTP. In all other cases, use the default value.

NO

CSSMTP rejects a mail message as an error if the data length of message lines, including the CR/LF characters exceeds 1000 bytes. This is the default behavior and is compatible with RFC 2821. It is suggested to use this value.

YES

If lines within a mail message exceed 1024 bytes, CSSMTP truncates message lines at 1024 bytes and continues processing the mail message. This value mimics the behavior of the SMTPD daemon.

Guideline: When DataLineTrunc is set to Yes, repair the line lengths of mail messages that are generated in JES spool. This function is not compatible with RFC 2821. Mail messages that are sent with line lengths longer than 1000 bytes can be rejected or truncated by successive SMTP gateways.

AtSign

Specifies the at sign symbol that is used in SMTP mail message commands and headers. CSSMTP updates mail message commands and headers by replacing the specified AtSign symbol with the industry standard at sign symbol @. Note that mail messages that are using the industry standard at sign symbol are not changed.

@

This is the default value.

symbol

symbol is the at sign character that is used in mail message commands and headers. It can be any character except the following:
 ABCDEFGHIJKLMNOPQRSTUVWXYZ0123456789abcdefghijklmnopqrstuvwxyz+*,.&()'-
 =:"%<>?;\

Tips:

- If you do not want the mail subject line to be updated, you can set the ReplaceSubjectAtSign option to No.

- This parameter simplifies migration from SMTPD to CSSMTP for customers that use a code page other than the default IBM-1047 and that have modified mail generation programs to generate mail addresses with an at sign character other than the industry standard @. To avoid updating existing mail generation programs when migrating from SMTPD to CSSMTP, you can configure the AtSign parameter with the character that is used by the mail generation programs for the at sign. CSSMTP updates mail message commands and headers by replacing the specified AtSign symbol with the industry standard at sign symbol @.

Guideline: If you want to specify the AtSign symbol in a code page other than the default IBM-1047, use the CSSMTP_CODEPAGE_CONFIG environment variable.

Result: If the AtSign option is not specified, the default value @ is processed using code page IBM-1047.

TLSEhlo

Specifies whether an EHLO SMTP command is sent after a successful TLS negotiation.

NO

EHLO command is not sent after a successful TLS negotiation. This is the default value.

YES

EHLO command is sent after a successful TLS negotiation.

Tip: Configure TLSEhlo Yes to enable communication with a mail server that requires an EHLO command after a successful TLS negotiation. RFC 3207 (SMTP Service Extension for Secure SMTP over Transport Layer Security) specifies that sending an EHLO command is optional for a SMTP client after a successful TLS negotiation. However, some SMTP servers require an EHLO command after a successful TLS negotiation. To communicate with these servers, configure TLSEhlo Yes. For more information on enabling the SMTP client to use Transport Layer Security (TLS), see [Steps for using Transport Layer Security for CSSMTP](#) in [z/OS Communications Server: IP Configuration Guide](#).

ReplaceSubjectAtSign

Specifies whether the mail subject line should be updated based on the setting of the AtSign option.

Yes

The mail subject line will be updated based on the setting of the AtSign option. This is the default.

No

The mail subject line will not be updated based on the setting of the AtSign option.

REPORT statement

Use the REPORT statement to indicate the action you want to take for reporting problems with JES spool files. These problems include the following ones:

- Errors accessing or reading the spool file
- SAF (RACF) violations
- User exit rejection of a mail message or the spool file
- Syntax errors in the spool file.
- Unsuccessful delivery. See [“UNDELIVERABLE statement”](#) on page 1271 for details.

Tip: For a description of an error report, see the example of an [error report to MailAdministrator](#) or the [sysout file](#) in [z/OS Communications Server: IP Diagnosis Guide](#).

Syntax

Parameters

Admin

Indicates that an error report should be sent to the configured mail administrators.

Tip: To avoid losing the error report information in the event that it cannot be delivered to one or more configured mail administrators, code `DeadLetterAction` store in the [“UNDELIVERABLE statement”](#) on page 1271.

Requirement: At least one mail administrator must be defined.

None

Indicates that no error reports should be created.

Without a report, the log must be inspected for messages about any problems found in the JES spool file.

Sysout

Indicates that CSSMTP should create a sysout file that contains the report.

ReportMailFrom statement

Use the `ReportMailFrom` statement to specify the email address with the format *userid@host.domain* (mailbox) that Communications Server SMTP (CSSMTP) uses in the MAIL FROM field when it delivers error reports to the mail administrator. Error reports are generated by CSSMTP when a problem is detected while processing a spool file from the JES subsystem. See [“REPORT statement”](#) on page 1260.

Syntax

Parameters

mailbox

mailbox is an e-mail address that CSSMTP uses in the MAIL FROM field when it delivers error reports. There is no default value.

Restrictions:

- The *mailbox* value is case sensitive.
- The *mailbox* value must be defined as *userid@host.domain* for the mail address.
- The *userid* value can be 1 - 64 characters in length. The *host.domain* value can be 1 - 255 characters in length.

ReportSysoutClass statement

Use the `ReportSysoutClass` statement to specify the SYSOUT class to which Communications Server SMTP (CSSMTP) delivers error reports. The class has to be single character that can be A - Z or 0 - 9. Error reports are generated by CSSMTP when a problem is detected while processing a spool file from the JES subsystem. See [“REPORT statement”](#) on page 1260.

Syntax

Parameters

SysoutClass

The SYSOUT class to which the CSSMTP delivers error reports.

Results:

- Only one ReportSysoutClass can be defined.
- When configured, a report is sent to the specified SYSOUT class for each spool file that contains errors. See [“REPORT statement” on page 1260](#).

Restriction:

- The SysoutClass value must be defined as a single character. The valid character can be A - Z or 0 - 9.

RetryLimit statement

Use the RetryLimit statement to set the limits that Communications Server SMTP (CSSMTP) uses when attempting to resend mail messages that are not immediately deliverable. See the information about Terms and concepts in [z/OS Communications Server: IP Configuration Guide](#) for description.

After the retry limit specified on this statement is exhausted the following actions occur:

- CSSMTP uses the setting on the Interval parameter of the ExtendedRetry statement to determine whether the mail message is eligible for extended retry. If the mail message is eligible, CSSMTP sends it for extended retry processing. If the mail message is not eligible for extended retry, the message goes immediately to the undeliverable process as specified by the [“UNDELIVERABLE statement” on page 1271](#).
- CSSMTP uses the setting in the ReturnToMailFrom parameter in the UNDELIVERABLE statement to determine its next action when there is information regarding the mail sender's address.
- CSSMTP attempts to send the undeliverable mail notifications to the originator of the mail message, through the configured target servers. If the notification cannot be sent on the first try, it becomes a dead letter (see [“UNDELIVERABLE statement” on page 1271](#)). No retries are made.

See [“ExtendedRetry statement” on page 1250](#) for a description of the actions that you need to take when a mail message is eligible for extended retry processing.

Syntax

➤➤ RetryLimit — Put Braces and Parameters on Separate Lines ➤➤

Put Braces and Parameters on Separate Lines

RetryLimit Parameters

Parameters

Count number

Indicates the number of times CSSMTP attempts to resend mail. Valid values are in the range 0 - 120. The default is 5.

Interval minutes

Indicates the amount of time, in minutes, that CSSMTP waits before attempting to resend mail. Valid values are in the range 0 - 120. The default value is 1.

If the Count or Interval value is zero, then no long retry is performed, and mail becomes undeliverable if it cannot be delivered to the target servers on the first try.

Restriction: The total configured time cannot exceed 5 days (7200 minutes in total). For example, 120 retries with 60 minutes per retry results in a maximum time of 5 days.

Tip: During this time, the spool file remains in use. A high configured time total can result in excess spool and storage usage. You can use the `MODIFY FLUSHRETRY,TKID=` command to force mail messages off the retry queue earlier than the configured time allowed in the `RetryLimit` statement. If you do, the values in the `RetryLimit` statement are no longer used for these mail messages. If the mail messages cannot be sent, then the mail messages become undeliverable messages.

SMF119 statement

Use the SMF119 statement to indicate which SMF records are written by Communications Server SMTP (CSSMTP).

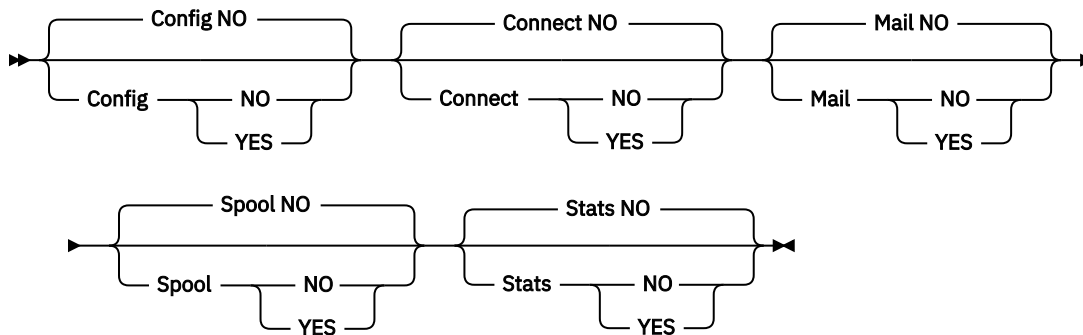

Syntax

►► SMF119 — Put Braces and Parameters on Separate Lines ◄◄

Put Braces and Parameters on Separate Lines

SMF119 Parameters

Parameters

Config

Specifies if the configuration SMF records are written

NO

The configuration SMF records are not written. This is the default.

YES

The configuration SMF records are written. The configuration SMF records are written at initialization and when the configuration is updated with the `MODIFY REFRESH` command.

Connect

Specifies if the connection SMF records are written

NO

The connection SMF records are not written. This is the default.

YES

The connection SMF records are written. The connection SMF records are written at the end of each client connection used for mail data transfer to a target server.

Mail

Specifies if the mail message SMF records are written

NO

The mail message SMF records are not written. This is the default.

YES

The mail message SMF records are written. The mail message SMF records are written at the completion of each mail message from the spool data set.

Spool

Specifies if the spool SMF records are written

NO

The spool SMF records are not written. This is the default.

YES

The spool SMF records are written. The spool SMF records are written when all the mail messages for a JES spool file have been processed.

Stats

Specifies if the statistical SMF records are written. The statistical SMF records are written at the MVS SMF intervals and at CSSMTP termination. For information about SMF interval processing, see the section about INTVAL and SYNCVAL - Performing interval accounting in [z/OS MVS System Management Facilities \(SMF\)](#).

NO

The statistical SMF records are not written. This is the default.

YES

The statistical SMF records are written.

TargetServer statement

Use the TargetServer statement to specify one or more target servers (resolved or configured IP addresses) and their connection attributes. CSSMTP establishes connections to the target servers in order to send mail.

Rules:

- If you are configuring the TargetIP parameter, the TargetName parameter, or both, then you can configure multiple TargetServer statements.
- When you issue a MODIFY REFRESH command, if the order of the target servers changes, the configuration is updated.
- Each TargetIP or TargetName must be unique.

Results:

- Only the first four unique TargetIP values, TargetName values, or both values are used. If more than four values are configured, the application issues a console message and logs a warning. The four target servers that are selected are based on the configuration order in which the parameters were configured. CSSMTP only uses the first four IP addresses.
- If duplicate target server IP addresses are resolved from the configured TargetIP or from the TargetName IP addresses, CSSMTP issues a console message and logs a warning.
- If the TCP/IP stack supports only IPv4, any configured IPv6 addresses are ignored and the application issues a console message and logs a warning.

Restrictions:

- You must define at least one TargetServer statement, and it must contain at least one TargetIP, TargetName, or TargetMx parameter.
- Only four TargetServer statements or the first four TargetIP and TargetName parameters with TargetServer statements are used.
- If distinct target servers can be reached by way of a single IP address, the target servers must have the same capabilities. For example, if a dynamic VIPA (DVIPA) address is specified, the mail servers for that DVIPA address must have the same capabilities. In this example, all the servers must be ESMTPs or SMTPs, but not both, that have the same capabilities.
- You can configure only one TargetMx parameter.

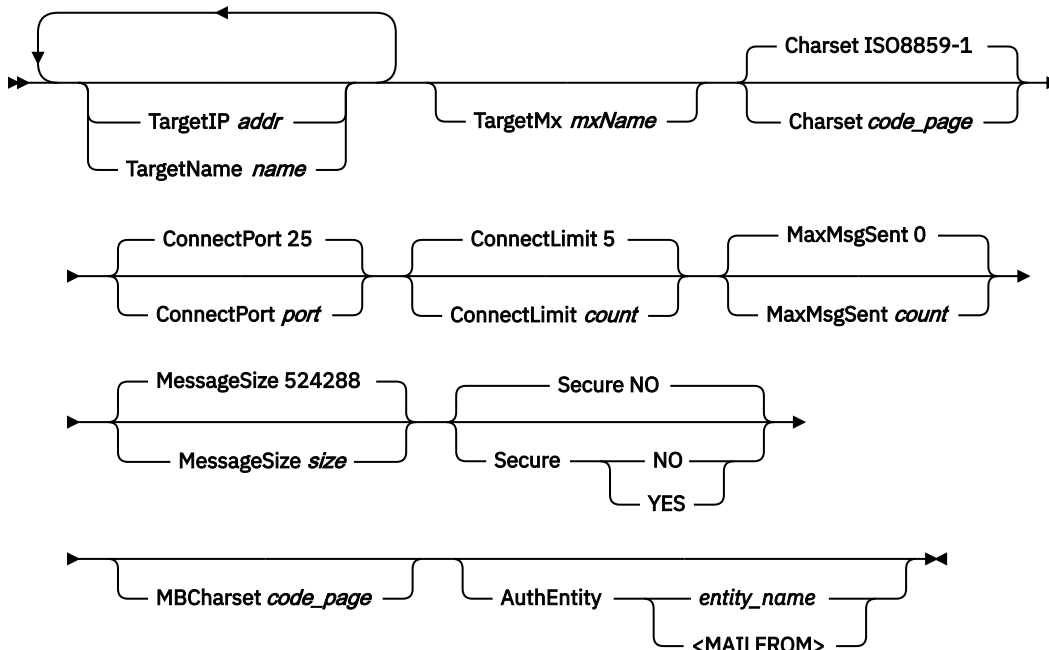

Syntax

➤ TargetServer — Put Braces and Parameters on Separate Lines ➤

Put Braces and Parameters on Separate Lines

TargetServer Parameters

Parameters

AuthEntity

AuthEntity is configured to indicate support for SMTP AUTH and to provide information to access the username and password needed when the target server sends an AUTH request. If a single username and password can be used to authenticate with the target server, AuthEntity should be configured with an *entity_name* that defines the SAF LDAPBIND profile name used to retrieve the username and password in support of SMTP AUTH. If the target server sends an AUTH request, CSSMTP will reply with the username and password retrieved from the SAF LDAPBIND entity *entity_name*.

If email level authentication is needed, AuthEntity should be configured with the <MAILFROM> parameter. An SAF LDAPBIND profile must be created for each email address that can be included in the MAIL FROM field of an email being sent to the target server. If the target server sends an AUTH

request, CSSMTP will reply with the username and password retrieved from the SAF LDAPBIND entity associated with the email address.

If an update to the AuthEntity value is detected during a dynamic refresh, CSSMTP will terminate all active connections to the target server that is associated with this TargetServer statement in order to use the username and password associated with the new AuthEntity value.

Restriction:

- If AuthEntity is configured, Secure Yes must also be configured for this TargetServer.
- For SMTP Auth support, the preferred specification of the target server is via the TargetName parameter. The specified host name is used for comparison to the host name in the target server certificate as recommended by the SMTP AUTH specification. If the TargetIP parameter is used, a lookup is done to determine the host name for comparison to the host name in the server certificate. The authentication attempt will fail if the host names do not match.
- Most mail servers only include AUTH LOGIN/PLAIN in the EHLO response after a TLS session has been established. To ensure that CSSMTP receives this notification, configure TLSEHLO YES on the OPTIONS statement in the CSSMTP configuration.
- The maximum length for *entity_name* is 246 characters. If using AuthEntity <MAILFROM>, make sure email addresses in the Mail From field are 246 characters or less.
- If the Configuration option Undeliverable is set to ReturnToMailFrom, then the ReportMailFrom parameter must also be configured. CSSMTP uses the ReportMailFrom email address to authenticate the undeliverable mail. If the ReportMailFrom parameter is empty, the undeliverable mail goes to the DeadLetterDirector.

Charset

Charset defines the code page that the target server expects to be used for mail messages when MBCS is specified as NO.

Result: If an update to the Charset value is detected during a dynamic refresh, CSSMTP must terminate all active connections to the target servers that are associated with this TargetServer statement to use the new Charset value.

Requirements:

- The code page must be defined to Unicode Systems Services.
- There must be a translation to and from the IBM-1047 code page to the Charset code page.
- There must be a translation from the TRANSLATE code page to the Charset code page.

The default code page is ISO8859-1.

For a list of Unicode character set code pages, the Language Environment (LE) **iconv** command can be used.

Example: **iconv -l | grep ISO** lists all the code page names that begin with ISO:

```
813      ISO8859-7
819      ISO8859-1
912      ISO8859-2
914      ISO8859-4
915      ISO8859-5
916      ISO8859-8
920      ISO8859-9
921      ISO8859-13
923      ISO8859-15
1089     ISO8859-6
5052     ISO-2022-JP
```

ConnectPort

Defines the port that CSSMTP uses to connect to a target server.

Result: If an update to the port is detected during a dynamic refresh, then CSSMTP must terminate all the active connections to the target servers that are associated with this TargetServer statement in order to use the new port value.

Requirement: This port must match the listening port number used by the target server.

The valid range of port values is 1 - 65535. The default port is 25.

ConnectLimit

Limits the number of concurrent socket connections to the target server from CSSMTP. This might be useful if your server has a concurrent connection limit. One of the socket connections is used by CSSMTP to monitor the SMTP server.

The valid values are in the range 2 - 5. The default limit is 5 connections.

Result: If an update to the ConnectLimit value is detected during a dynamic refresh, CSSMTP must terminate all the active connections to the target servers that are associated with this TargetServer statement in order to use the new limit.

MaxMsgSent

Specifies the maximum number of mail messages that can be sent on a single connection. When the MaxMsgSent value is exceeded, CSSMTP closes the connection to the target server and reestablishes a new connection to the same target server. Mail messages continue to be sent over the new connection until the MaxMsgSent value is reached again.

The valid range is 0 - 2147483647. The default is 0, which means that an unlimited number of messages can be sent.

MBCharset

Defines the code page that the target server expects to be used for mail messages when MBCS is specified as YES.

Result: If an update to the MBCharset value is detected during a dynamic refresh, CSSMTP must terminate all active connections to the target servers that are associated with this TargetServer statement to use the new MBCharset value.

Requirements:

- The code page must be defined to Unicode Systems Services.
- There must be a translation to and from the IBM-1047 code page to the MBCharset code page.
- There must be a translation from the TRANSLATE code page to the MBCharset code page.

There is no default MBCharset code page.

MessageSize

Specifies the maximum size of a mail message that can be sent to target servers that do not support ESMTP size extensions.

Valid values are in the range 1000 - 2147483647. The default size is 524288 bytes (512 KB).

Secure

Indicates whether Transport Layer Security (TLS) is required between the client and a target server. TLS provides private, authenticated communication over the internet. See the steps [for setting up security for CSSMTP in z/OS Communications Server: IP Configuration Guide](#).

Result: If an update to the secure value is detected during a dynamic refresh, CSSMTP must terminate all the active connections to the target servers that are associated with this TargetServer statement in order to use the new secure value.

NO

TLS is not required between CSSMTP and a target server. However, if the STARTTLS SMTP command is used in the spool file, a TLS connection is attempted with this server.

YES

TLS is required between CSSMTP application and a target server. If a TLS session cannot be established, then the server is not usable.

TargetIP

The IPv4 or IPv6 address of the target server to which CSSMTP connects.

Restrictions:

- IPv4-mapped IPv6 addresses and IPv6 addresses with the reserved prefix `::/96` are not valid.
- The IPv6 unspecified address `:::0` and IPv4 unspecified address `(0.0.0.0)` are not allowed.
- Duplicate IP addresses are not allowed.

TargetName

The host name or fully qualified host name used for a resolver A or AAAA query. Valid values are 1 - 255 characters in length. If the host name is used, the resolver appends the domain information, which is obtained from the TCPIP.DATA data set.

The TargetName value is not case sensitive.

Result: CSSMTP only uses the first four configured or resolved IP addresses to send the mail message. If more than four target servers are found, this application issues a console message and logs a warning.

Restriction: Duplicate host names are not allowed.

TargetMx

The name or a fully-qualified domain name used for a resolver MX query. This name might resolve into multiple MX records that include a preference value. The lower the preference value is, the more likely that the record is used. Valid values are 1 - 255 characters in length.

The lower the value, the higher the preference.

The TargetMx value is not case sensitive.

Results:

- Only the first configured TargetMx value is used. If more than one value is configured, the application issues a console message and logs a warning.
- Only the first four target servers are saved for the configured TargetMx value. If more than four target servers are returned, CSSMTP issues a console message and logs a warning.
- The lower preference is honored by not sending mail messages to those IP addresses unless the higher preference target servers are unavailable.

Restriction: The TargetMx parameter is mutually exclusive with the TargetName parameter and the TargetIP parameter. If you want to use this statement, MX records for this TargetMx value must exist in the DNS database. If no MX records are found then this is handled as an error and console message EZD1815E is generated.

TIMEOUT statement

Use the Timeout statement to define a set of timeout values, in seconds, for the interaction between CSSMTP and the target server.

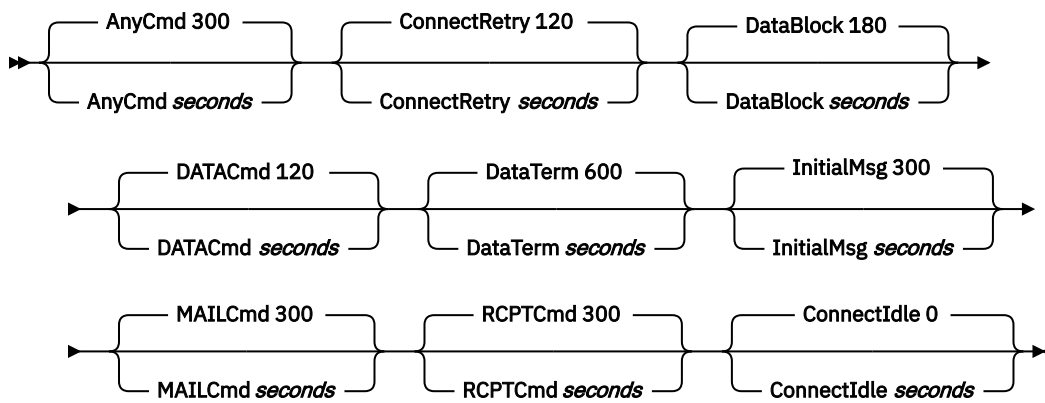

Syntax

►► Timeout — Put Braces and Parameters on Separate Lines ◄◄

Put Braces and Parameters on Separate Lines

```
►► {
    Timeout Parameters
} ◄◄
```

Timeout Parameters

Parameters

AnyCmd

The length of time, in seconds, that CSSMTP waits for a response on any other SMTP command (for example, EHLO, HELO, RSET, QUIT, and STARTTLS) from the SMTP server.

Valid values are in the range 30 - 1 200. The default value is 300.

ConnectRetry

The length of time, in seconds, that CSSMTP waits before trying again to connect to a target server after a failed attempt.

Valid values are in the range 30 - 1 200. The default value is 120.

DataBlock

The length of time, in seconds, that CSSMTP waits for the TCP send call to complete while transferring a block of data to the TCP/IP stack .

Valid values are in the range 30 - 1 200. The default value is 180.

DATACmd

The length of time, in seconds, that CSSMTP waits for a response to the DATA command from the SMTP server.

Valid values are in the range 30 - 1 200. The default value is 120.

DataTerm

The length of time, in seconds, that CSSMTP waits for a response to the final period that terminates the mail message data from the SMTP server.

Valid values are in the range 30 - 1 200. The default value is 600.

InitialMsg

The length of time, in seconds, that CSSMTP waits for an initial response after the connection is established with the SMTP server.

Valid values are in the range 30 - 1 200. The default value is 300.

MAILCmd

The length of time, in seconds, that CSSMTP waits for a response to the MAIL command from the SMTP server.

Valid values are in the range 30 - 1 200. The default value is 300.

RCPTCmd

The length of time, in seconds, that CSSMTP waits for a response to the RCPT command from the SMTP server.

Valid values are in the range 30 - 1 200. The default value is 300.

ConnectIdle

The length of time, in seconds, to keep a connection with a target server after processing the last mail message in a JES spool file if another spool file is not immediately available for processing.

Valid values are in the range 0 – 65535. The default value is 0 that indicates that the connection with the target server is dropped when the last mail message in a spool file is processed if another spool file is not immediately available for processing.

Result: If the target mail server implements an idle timeout that expires before CSSMTP's idle timeout, the target server closes the connection. This is not an error. If CSSMTP attempts to send a mail message when the target server closes the connection, the mail message might be treated as undeliverable, which causes the normal CSSMTP retry logic to be used.

Guideline: If the target mail server implements an idle timeout, set this value to be shorter than the value of the target server to avoid retries.

Result: This value does not override any other configuration related logic. For example, if a target server is removed from the list in a configuration refresh, connections to the target server are immediately stopped regardless of the setting of this parameter.

TRANSLATE statement

Use the TRANSLATE statement to define the supported code page to be used to translate data received from the JES spool data set to ASCII for sending mail messages. See the code set conversions supplied in *z/OS Support for Unicode: Using Unicode Services* for details about the supported code pages.

Tip: The following POSIX variant characters are converted to ASCII using *iconv* determined by the configured EBCDIC code page. The POSIX variant characters are:

\ [] { } ^ ~ ! # | \$ @ `

Syntax

Parameters

Translate

Specifies the code page to be used for translating the spool file records. If you do not specify this statement, the default code page is IBM-1047. See Table 107 on page 1273 under “CSSMTP environment variables” on page 1273 for a list of supported single-byte code pages. See Table 106 on page 1257 under “MBCS statement” on page 1257 for a list of supported multi-byte code pages.

Results:

- If an update to the Translate statement is detected during a dynamic refresh, CSSMTP continues to use the old translate value and a warning message is written to the log and the console.
- If the specified code page does not support all the characters, CSSMTP continues with a warning message EZD1853I written to console and the CSSMTP log. The CSSMTP log contains additional diagnostic messages. CSSMTP is initialized. However, if mail commands or headers contain characters that cannot be translated to IBM-1047, mail message processing can fail.

Restrictions: The code page must have the following characteristics:

- Defined to Unicode System Services
- An EBCDIC code page
- If the MBCS statement specifies NO, TRANSLATE must specify a single byte code page
- If the MBCS statement specifies YES, TRANSLATE must specify a multi-byte code page

- A translation to and from the ASCII character set specified on the Charset parameter of the target server
- A translation to and from the ASCII character set specified on the MBCharset parameter of the target server when the MBCS statement specifies YES
- If user-defined conversion tables are not used, the environment variable `_ICONV_TECHNIQUE` should be left undefined or have the value of its default LMREC. If user-defined conversion tables are used, value should be preceded with the technique used to generate the table. For example, if the table was generated using technique 0, the value should be set to 0LMREC.

UNDELIVERABLE statement

Use the UNDELIVERABLE statement to indicate to CSSMTP the method used for handling undeliverable mail. See the information about [Terms and concepts](#) in [z/OS Communications Server: IP Configuration Guide](#) more details.

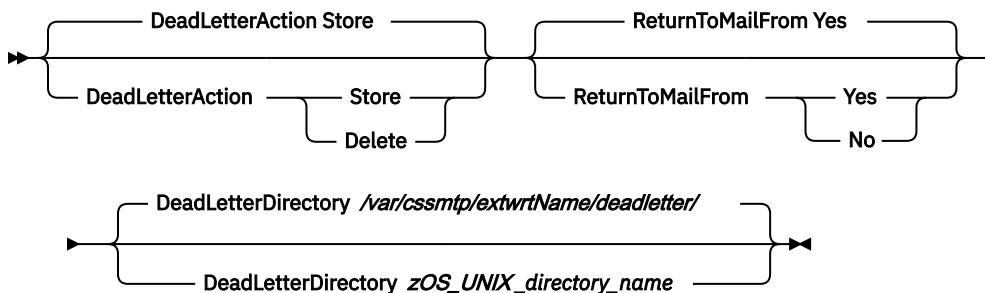

Syntax

►► UNDELIVERABLE — Put Braces and Parameters on Separate Lines ◄◄

Put Braces and Parameters on Separate Lines

UNDELIVERABLE Parameters

Parameters

DeadLetterAction

Indicates to CSSMTP the action to take when a dead letter is detected. A dead letter is an undeliverable mail notification that cannot be returned to the original sender or that an error report, if requested, could not be delivered to the mail administrators. This can occur if the MAIL FROM: value is null in the original spool file and it cannot be sent. See the information about [Terms and concepts](#) in [z/OS Communications Server: IP Configuration Guide](#) for a description of dead letter.

Delete

Indicates that CSSMTP should not save the dead letter to a z/OS UNIX file system. If this option is chosen then it is recommended that you use the report statement. See the Sysout parameter in ["REPORT statement"](#) on page 1260 for information about recording original spool problems.

Store

Indicates that CSSMTP should store the mail message to the directory defined in the DeadLetterDirectory parameter. Each dead letter is stored as a separate file within the dead letter directory.

DeadLetterDirectory

The z/OS UNIX file system fully qualified directory name where CSSMTP creates the dead letter mail message that is stored when the DeadLetterAction parameter is set to Store. Valid values are 1 - 512 characters in length and must begin with a slash (/) to define the fully qualified directory. The default dead letter directory is /var/cssmtp/extWrtName/deadletter, where the extWrtName is the name used for ExtWrtName. See the information about [Terms and concepts](#) in [z/OS Communications Server: IP Configuration Guide](#) for a description of a dead letter.

Result: An ending slash (/) is added to the directory name if not configured.

ReturnToMailFrom

Indicates whether CSSMTP should create an undeliverable mail notification to be returned to the originator. The undeliverable mail notification contains the original mail message as well as additional information indicating the reason for the failure. This parameter does not apply to original mail messages that do not have the originator specified on the MAIL FROM SMTP command (for example, MAIL FROM:<>). In this case, if the original mail message cannot be sent, it immediately becomes a dead letter.

YES

CSSMTP creates the undeliverable mail notification to be returned to the originator with additional information regarding the reason for the failure.

Result: If the original spool file contains no errors other than undeliverable errors, the spool file is deleted.

NO

CSSMTP does not create the undeliverable mail notification to be returned to the originator. If you specify this parameter, you should use the REPORT statement with a value of *sysout* or *admin..* See [“REPORT statement” on page 1260](#) for information about how to create a report that the original mail message is undeliverable.

The action taken on the original spool file that contained undeliverable errors is based on the value configured on the BadSpoolDisp statement. See [“BadSpoolDisp statement” on page 1249](#) for details.

Results:

- If DeadLetterAction is set to Store:
 - If the DeadLetterDirectory parameter, to set the dead letter directory, is set to /userDirectory/deadLetterDirectory, then CSSMTP creates the userDirectory, deadLetterDirectory, or both in the z/OS UNIX file system if they do not already exist. The following name is the file name that would be used for the dead letter that is stored on the configured directory. The file name, TESTMAIL.SYS00006.Sep302008.160454.541437.1U, is constructed from the message ID of the mail message in the original spool file with the letter *U* appended and the fully-qualified host name removed. See the SMTP command and data command information in [z/OS Communications Server: IP User's Guide and Commands](#) for details about the Message-ID.

The following sample shows a dead letter directory (/userDirectory/deadLetterDirectory) that contains two dead letters:

```
/userDirectory/deadLetterDirectory/TESTMAIL.SYS00006.Sep302008.160454.541437.1U
/userDirectory/deadLetterDirectory/TESTMAIL.SYS00006.Sep302008.160454.541999.1U
```

Figure 50. Code sample

- If the configured dead letter directory already exists, then CSSMTP uses the existing directory.
- If the directories cannot be created during parsing of the configuration file, CSSMTP generates a configuration error.

USEREXIT statement

Use the USEREXIT statement to specify whether or not CSSMTP calls the CSSMTP exit program to interrogate data that is sent to CSSMTP from the JES spool data set.

Requirement: You must install a CSSMTP exit program for this function to work correctly. For more information about the CSSMTP exit program, see [“CSSMTP user exit version 3 and version 4” on page 1275](#).

The user exit value on MODIFY REFRESH or MODIFY USEREXIT command is not changed until the next JES spool file is opened.

Syntax

Parameters

NONE

The CSSMTP user exit is not called. You can use the commands that are documented in RFC 821 and RFC 2821. This is the default value.

VERSION2

The CSSMTP user exit that uses the exit facility token name EZBTCPIPSMTPEXIT is called. Using VERSION2 allows only RFC 821 syntax for the mail read from the JES spool data set. The RFC 2821 commands are not accepted. The exit routine for the previous batch SMTP version continues to function.

VERSION3

The CSSMTP user exit that uses the exit facility token name EZATCIPCSSMTPV3 is called. Use VERSION3 to read and to process both RFC 821 and RFC 2821 commands from the JES spool data set.

VERSION4

The CSSMTP user exit that uses the exit facility token name EZATCIPCSSMTPV4 is called.

Use VERSION4 to read and to process both RFC 821 and RFC 2821 commands from the JES spool data set.

CSSMTP environment variables

The CSSMTP_CODEPAGE_CONFIG environment variable is for Communication Server SMTP (CSSMTP). The variable is used to set the supported EBCDIC single-byte code page used by the configuration file to convert to EBCDIC IBM-1047. The following code pages are supported:

Table 107. Code pages known to work with CSSMTP	
Code page	Description
IBM-037	USA, CANADA, BRAZIL, AND COMMON EUROPE
IBM-273	AUSTRIA AND GERMANY
IBM-277	DENMARK NORWAY

61696	GLOBAL USE
61711	GLOBAL USE
61712	GLOBAL USE

See the code set converters supplied in *z/OS Support for Unicode: Using Unicode Services*.

Result: This code page is not used for JES spool files. See [“TRANSLATE statement” on page 1270](#) for JES code page information. The default is EBCDIC IBM-1047.

CSSMTP user exit version 3 and version 4

Use the Communication Server SMTP (CSSMTP) exit to check, and subsequently accept or reject, outbound mail from the JES spool data set. For example, you can code an exit to check the MAIL FROM: string on outbound mail.

CSSMTP uses the Dynamic Exit Facility (CSVDYNEX macro) provided by MVS. See [z/OS MVS Programming: Assembler Services Guide](#) for more information.

The USEREXIT statement in the CSSMTP configuration, along with the MODIFY CSSMTP,USEREXIT command, defines which user exit is called by CSSMTP. For compatibility with the SMTP server, VERSION2 is provided. VERSION3 is provided to take advantage of the additional features provided by CSSMTP. VERSION4 is like VERSION3 but also provides information about the job that spooled the SYSOUT including the jobname, the job ID, and the job userid.

A sample VERSION3 user exit is included in member CSSMTPV3 in SEZAINST. The name of the macro is EZAYSMTP and the macro is located in SEZANMAC.

The parameter list for the VERSION4 user exit is generated by specifying VERSION=4 on the EZAYSMTP macro call.

Example:

```
EZAYSMTP VERSION=4
```

[Table 108 on page 1276](#) provides a definition for the VERSION2, VERSION3, and VERSION4 user exits.

Table 108. USEREXIT comparisons			
Feature	VERSION2	VERSION3	VERSION4

EZBAEHLO (19)	No	Yes	Yes
EZBASTAR (20)	No	Yes	Yes

If the USEREXIT statement specifies VERSION2, then only RFC 821 syntax for the mail read from JES spool files is allowed. If the USEREXIT statement specifies VERSION3 or NONE, then RFC 821 and RFC 2821 syntax for the mail read from JES spool file is allowed. See [“USEREXIT statement” on page 1272](#) for more information.

CSSMTPV3 is provided as a programming guide to aid in the implementation of the local policies. It can be found in SEZAINST. If using the CSSMTP exit, a name token (EZATCIPCSSMTPV3) must be established in SYS1.PARMLIB(PROGxx). If using the VERSION4 CSSMTP exit, a name token (EZATCIPCSSMTPV4) must be established in SYS1.PARMLIB(PROGxx). See [z/OS MVS Initialization and Tuning Guide](#) for more information.

You can use the SETPROG EXIT command to activate and deactivate EZATCIPCSSMTPV3 or EZATCIPCSSMTPV4 exit routines. See [z/OS MVS System Commands](#) for more information.

When you design the CSSMTP exit, consider some of the following design points. Code the exit as efficiently as possible; take all efforts to avoid excessive processing or waiting (for example, I/O operations and DNS resolver calls, while within the exit). Efforts to reject mail might be more efficient if extensive scanning of the data portion of the mail message can be avoided. The exit can allow processing to continue or reject the entire mail message and does not have the ability to reject individual segments of a mail message. The mail message contents cannot be changed in any way by the exit. The exit can accept a mail message at any point and disable further exit calls for that mail message. Only commands that are currently implemented by the CSSMTP program and that are syntactically correct are passed to the exit program.

Read and understand RFCs 2505 and RFC 2635 before undertaking this coding effort. More information about CSSMTP commands and standards are documented in RFCs 2821 and 2822.

The CSSMTP dynamically determines if a CSSMTP exit program exists. This determination is based upon the CSSMTP exit program association with the name token EZATCPIPCCSMTPV3 or EZATCPIPCCSMTPV4 using the MVS SETPROG command. If you determine that the exit program needs to be called to interrogate data coming from the JES spool data set, follow these steps:

This topic describes how to call the exit program to interrogate data coming from the JES spool data set.

Perform the following steps to call the exit program to interrogate data coming from the JES spool data set:

1. Add code to the user exit program so that the program is compatible with the JES connection.

Rules:

- The connection ID is always the value 257.
- The EZBPIPV4 field that represents the remote IP address is always 0 for the JES connection.

For SAF token information, the EZBPTOKP field contains the address of the token. The SAF token length is 80 bytes and the SAF token version is 1. The SAF token provides information about the submitting user ID and the submitter node of the JES data. This data can be compared to the sender information about the MAIL FROM: string. For more information about what is provided in the SAF token, see the ICHRUTKN information in [z/OS Security Server RACF Data Areas](#).

2. Compile the user exit with the version 3 or version 4 copy of the EZAYSMTP DSECT. This action recognizes the changes in the parameter list.

Specify the user exit version in the VERSION parameter of the EZAYSMTP macro call.

Examples:

EZAYSMTP VERSION=3	Generate version3 parameters
EZAYSMTP VERSION=4	Generate version4 parameters

3. Write the exit in Assembler language. You must use standard z/OS Assembler entry and exit linkage. See [z/OS MVS Programming: Assembler Services Guide](#) for the linkage conventions.

A return code of 8 or 12 results in a reply message that is listed in the log and in the error report. The JES spool file is then subject to the action of the BadSpoolDisp statement. See [“BadSpoolDisp statement”](#) on page 1249 for details. See [“Registers at exit”](#) on page 1282 for details about exit return codes.

The user exit is passed by the generated undeliverable mail notification and the error report.

Restriction: This exit must be reentrant and amode 31 in an authorized library.

The exit is invoked with the settings shown in [Table 109 on page 1278](#).

Table 109. CSSMTP user exit settings	
Exit	Description
Authorization	Problem state
Dispatchable unit mode	Task
Cross memory mode	PASN=HASN
Amode	31-bit
ASC mode	Primary address space control (ASC) mode
Interrupt status	Enabled for interrupts
Locks	Unlocked

Table 109. CSSMTP user exit settings (continued)	
Exit	Description
Control parameters	In the caller's primary address space

Registers at entry

On entry to the exit, the register contents are:

Register 0

Used as a work register by the system.

Register 1

Address of the exit's input parameter list. See [Table 110 on page 1279](#).

Registers 2-12

Unassigned.

Register 13

Address of a 36-word save area.

Register 14

Return address.

Register 15

Entry point address of the exit routine.

The exit input parameter list contains the information shown in [Table 110 on page 1279](#). An assembler macro is available that contains a DSECT describing this area. The name of the macro is EZAYSMTP and the macro is located in SEZANMAC. The macro enables an optional label but has no operands. The macro provides symbolic names for the four return codes and the twenty action codes. The labels are as shown in [Table 110 on page 1279](#).

Table 110. CSSMTP exit input parameter list			
Label name	Width or value	Description	Notes
Parameter list variables			
EZAYSMTP		DSECT Name	
EZBPVERS	One fullword	Version number	A word containing the version number three.
EZBPACTN	One fullword	Action code	An action code describing the buffer contents (if any).
EZBPUSER	One fullword	Returned Reg15 of initialization call	Contains the user supplied token from the EZBAINIT call.
EZBPCNID	One fullword	Connection ID	JES spool data always set to 257.
EZBPTOKP	One fullword	Address of SAF (security) token	SAF information is always returned. CSSMTP sets this field to a 31-bit address that points to the SAF (security) token information. See ICHRUTKN
	Two fullwords	Reserved	Reserved

Table 110. CSSMTP exit input parameter list (continued)

Label name	Width or value	Description	Notes
EZBPIPv4	One fullword	Reserved	Always 0.
EZBPDLEN	One fullword	Length of data in buffer	A word containing the actual length of the data in the buffer. If the buffer length is meaningless for the action code, the length is set to 0.
EZBPBUFF	One fullword	Buffer address	A word containing a 31-bit address that points to the actual buffer. If the buffer length is zero, do not use this parameter.
Return codes			
Label name	Width or value	Description	Notes
EZBRAGN	0	Return code to continue	The exit routine is called again.
EZBRACC	4	Return code to accept mail	The exit routine is not called again until the start of the next mail event.
EZBRREJ	8	Return code to reject entire JES spool file	Mail already accepted are processed and sent.
EZBRMAIL	12	Return code to reject the current mail	If a mail is in progress, it is not sent.
Action codes			
Label name	Width or value	Description	Notes
EZBAINIT	1	Initialization call	Buffer is empty, a return token is expected in R15 and saved in the EZBPUSER field.
EZBATERM	2	Termination call	The application shutting is down and exit return code is ignored. This call (and all others) might not occur during abnormal termination.
EZBADATA	3	RFC 2821 DATA command	
EZBAEXPN	4	RFC 2821 EXPN (expand) command	This action code is never passed to the CSSMTP exit
EZBAHELO	5	RFC 2821 HELO (hello) command	

Table 110. CSSMTP exit input parameter list (continued)

Label name	Width or value	Description	Notes
EZBAHELP	6	RFC 2821 HELP command	This action code is never passed to the CSSMTP exit.
EZBAMAIL	7	RFC 2821 MAIL command	
EZBANOOP	8	RFC 2821 NOOP command	This action code is never passed to the CSSMTP exit.
EZBAQUEUE	9	RFC 2821 QUEUE (queue) command	This action code is never passed to the CSSMTP exit.
EZBAQUIT	10	RFC 2821 QUIT command	
EZBARCPT	11	RFC 2821 RCPT (recipient) command	
EZBARSET	12	RFC 2821 RSET (Reset) command	
EZBATICK	13	IBM SMTP TICK command	This action code is never passed to the CSSMTP exit.
EZBAVERB	14	IBM SMTP VERB command	This action code is never passed to the CSSMTP exit.
EZBAVRFY	15	RFC 821 VRFY command	This action code is never passed to the CSSMTP exit.
EZBADBUF	16	Data buffer	Data buffer of approximately 1024 bytes of data or less. The data buffers are untranslated.
EZBAEODB	17	End of data buffers	End of data marker This is the last chance to reject this mail message.
EZBACONN	18	End of connection	End of file for JES spool data.
EZBAEHLO	19	RFC 2821 EHLO command	
EZBASTAR	20	RFC 2821 STARTTLS command	

There are two control invocations of the CSSMTP user exit. One for initialization and the other for termination. On return from the initialization call, the content of register 15 is treated as a 4-byte user token that is returned on all other exit invocations. See [Table 110 on page 1279](#) for more information. The user token is not used by CSSMTP but is only passed on subsequent calls to allow a re-entrant exit to have static data (using getmain or some other method). Certain data sets might be read during the initialization

call and tables of known spamming Internet addresses might be constructed at this time for later use. The termination call allows report generation or any other clean-up activity that the exit might do prior to the stopping of CSSMTP.

Registers at exit

Upon return from Communication Server SMTP (CSSMTP) exit processing, the register contents must be one of the types listed in [Table 111](#) on [page 1282](#).

<i>Table 111. Register contents upon return from CSSMTP exit processing</i>	
Register	Contents
0 - 14	Not applicable
15	<p>One of the following return codes:</p> <p>0 EZBRAGN - Continue to call the exit</p> <p>4 EZBRACC - Accept the current command or data, but do not call the exit again until the start of the next mail message.</p> <p>8 EZBRREJ - Reject the current JES spool file. Any mail already accepted is processed.</p> <p>12 EZBRMAIL - Reject the current mail message in progress.</p>

Return codes that are not valid are converted to the value 0, and processing continues as if the return code was EZBRAGN.

The buffer contents for action codes 3 through 15 or 19 through 20 contain the CSSMTP command. See RFC 2821 for exact syntax and format.

Unknown commands are rejected by CSSMTP and the exit is not called.

Guideline: The CSSMTP command can be uppercase, lowercase, or mixed case.

Interaction between CSSMTP and user exit program

While processing a JES spool file, the HELO, EHLO, MAIL, RSET and QUIT commands reset the last return code to EZBRAGN, which allows the DATA, RCPT, data buffer lines, and the end of mail message line to be processed. After a EZBRACC or EZBRMAIL code is returned from the user exit, the exit is not called again until the next command that resets the last return code is processed. If the EZBRREJ code is returned from the user exit, the spool file is not read again.

[Table 112](#) on [page 1282](#) shows the action code and return code results.

<i>Table 112. Action code and return code results</i>					
Action (value)	Last return code	RC= EZBRAGN	RC= EZBRACC	RC= EZBRREJ	RC= EZBRMAIL
EZBAINIT (1)	Ignored	Ignored	Ignored	Ignored	Ignored
EZBATERM (2)	Ignored	Ignored	Ignored	Ignored	Ignored
EZBADATA (3)	Call if EZBRAGN	Continued	Continued	End spool file	Reject mail

Table 112. Action code and return code results (continued)

Action (value)	Last return code	RC= EZBRAGN	RC= EZBRACC	RC= EZBRREJ	RC= EZBRMAIL
EZBAEXP (4)	This command is not implemented				
EZBAHELO (5)	Reset to EZBRAGN	Continued	Continued	End spool file	Ignored
EZBAHELP (6)	This command is not implemented				
EZBAMAIL (7)	Reset to EZBRAGN	Continued	Continued	End spool file	Reject mail
EZBANOOP (8)	This command is not implemented				
EZBAQUEUE (9)	This command is not implemented				
EZBAQUIT (10)	Reset to EZBRAGN	Continued	Continued	End spool file	Ignored
EZBARCPT (11)	Call if EZBRAGN	Continue	Continue	End spool file	Reject mail
EZBARSET (12)	Call if EZBRAGN	Continue	Continue	End spool file	Ignored
EZBATICK (13)	This command is not implemented				
EZBAVERB (14)	This command is not implemented				
EZBAVRFY (15)	This command is not implemented				
EZBADBUF (16)	Call if EZBRAGN	Continue	Continue	End spool file	Reject mail
EZBAEODB (17)	Call if EZBRAGN	Continue	Continue	End spool file	Reject mail
EZBACONN (18)	Ignored	Ignored	Ignored	Ignored	Ignored
EZBAEHLO (19)	Reset to EZBRAGN	Continued	Continue	End spool file	Ignored
EZBASTAR (20)	The STARTTLS command is processed.				

Chapter 25. sendmail to CSSMTP bridge

The z/OS sendmail to CSSMTP bridge (sendmail bridge) allows the user to send emails by using the facilities of the z/OS shell. The sendmail bridge command parses input command switches, reads the mail message from the UNIX System Services file, and processes the mail message. The input mail message is updated by adding SMTP commands and SMTP headers, if no headers are specified in the input mail message. The updated mail message is transmitted to the JES spool data set that is processed by the Communications Server SMTP (CSSMTP) application.

For more overview and configuration information about the sendmail bridge command, see information about the sendmail bridge in [z/OS Communications Server: IP Configuration Guide](#) and in [z/OS Communications Server: IP User's Guide and Commands](#).

sendmail bridge environment variable

Use the **EZATMAIL_CSSMTP_EXTWRTNAME=external_writer_name** environment variable to define the CSSMTP external writer name for the sendmail bridge. This method is useful when the user does not want to add a W configuration statement to define the CSSMTP external writer name.

The following list shows the search order for determining the CSSMTP external writer name:

- The -W command switch is specified
- The EZATMAIL_CSSMTP_EXTWRTNAME environment variable is used
- The W statement is specified in the configuration file
- Defaults to CSSMTP

General syntax rules for the sendmail bridge configuration file

The following list shows the general syntax rules for the sendmail bridge:

- Statements must start in column 1.
- If the first column is the number sign (#), then the rest of the line is treated as a comment and is ignored.
- If the first column is a blank or a tab, the line is treated as a continuation line.
- The statements that are only allowed once should be specified only once. When a single statement is repeated, the last instance of the statement is used.

sendmail bridge configuration file

The following list shows the search order for finding the configuration file:

- The -C command switch is specified
- /etc/mail/ezatmail.cf is located
- /etc/mail/submit.cf is located
- /etc/mail/sendmail.cf is located

If no configuration file is found, the sendmail bridge command fails.

sendmail bridge configuration statements

[Table 113 on page 1286](#) shows the sendmail bridge configuration statements.

Table 113. sendmail bridge configuration statements	
Configuration statement	Description
D	Define a macro definition
J	Define the JES output class for the mail files
O	Define an option
W	Define the CSSMTP external writer name

Tips:

- For unsupported configuration statements that the sendmail application supports in the previous releases, the sendmail bridge command ignores the configuration statements. A debug message is logged if the -d command switch is specified. The following is an example of an ignored configuration statement: "Ignore - Unsupported configuration statement 'Cwlocalhost'".
- For invalid configuration statements that the sendmail application does not support in the previous releases, the sendmail bridge command fails with an error logged. The following is an example of an invalid configuration statement: "ERROR: Line 0040 Unknown configuration statement 'YTST'".

D statement

The D statement is an optional statement.

Table 114. D statement		
Macro definition	Description	Example
Dj	Host name and domain name in the format of <i>host name.domain name</i>	Dj\$w.\$m Dj\$w.DOMAIN.IBM DjMVSTST1.DOMAIN.IBM
Dm	Domain name	DmDOMAIN.IBM
Dw	Short host name	DwMVSTST1
D{tls_version}	STARTTLS SMTP command is generated	D{tls_version}=tlsv1

Dj

Defines the host name and the domain name together and forms the fully qualified domain name of a host. This macro is used for creating the EHLO SMTP command and the MAIL FROM SMTP command. See [TCPIP.DATA HOSTNAME](#) and [DOMAIN](#).

Dm

Defines the domain name used for creating the EHLO SMTP command and the MAIL FROM SMTP command. See [DOMAIN](#) for details in [z/OS Communications Server: IP Configuration Guide](#).

Dw

Defines the short host name used for creating the EHLO SMTP command and the MAIL FROM SMTP command. See [TCPIP.DATA HOSTNAME](#) for details in [z/OS Communications Server: IP Configuration Guide](#).

D{tls_version}

Request Transport Layer Security (TLS) for messages sent by the sendmail bridge command. If D{tls_version} is specified, a STARTTLS SMTP command is generated. When CSSMTP processes the JES spool data set, CSSMTP ensures a secured connection between CSSMTP and its target server is

used to forward the mail message. The value that is defined by D{tls_version} is ignored. The secured connection is setup between CSSMTP and the target mail server based on configured AT-TLS policy.

J statement

The J statement is an optional statement.

Defines the JES spool dataset output class for the mail files. Valid range for output classes are from upper case A to Z and 0 to 9.

O statement

The O statement is an optional statement.

The following list shows the search order for finding the option parameter:

- The -O command switch is specified
- The O statement

Option	Description
O AliasFile= <i>location</i>	Define the AliasFile full path
O MaxAliasRecursion= <i>number</i>	Define the maximum recursive depth when resolving aliases
O MaxRecipientsPerMessage= <i>number</i>	Define the maximum recipients per mail message
O IgnoreDots= <i>boolean</i>	Treat any line that contains only a single period as ordinary text, not as an EOF indicator.

AliasFile

Defines the z/OS Unix File System full path of the alias file location. There is no default path. The alias file contains one or more specific recipients and can contain one or more ":include:" statements. The ":include:" statement is a file that contains the email addresses of one or more recipients .

Example:

O AliasFile=/tmp/aliaslist1

The /tmp/aliaslist1 alias file contains the following information:

```
tstrcpt1:      user1@work.com
tstrcpt2:      user2@work.com
group1:        tstrcpt1, tstrcpt2,
               tstrcpt3@work.com,
               tsprcpt4@work.com
list2:         :include:/tmp/aliaslist2
```

The /tmp/aliaslist2 statement contains the following information:

```
user100@work.com
user101@work.com
user102@work.com
```

You can issue the following sendmail command with group1 as the alias name:

```
sendmail -d0-99.100 -v group1 </tmp/mymail1
```

In this case, the following recipients are obtained:

```
user1@work.com
user2@work.com
tstrcpt3@work.com
tstrcpt4@work.com
```

Rules:

- If the first column is a # character, then the rest of the line is treated as a comment and is ignored.
- A blank line is treated as a comment and is ignored.
- The alias name is a character string ending with ":". The alias name should not include an @ character.
- A line with no ":" in it is a continuation line.
- The file referenced by an ":include:" statement must contain only recipient addresses, alias names are not allowed.

Tips:

- If AliasFile is specified, you can use the -n command switch to disable alias searches. For more information about the -n command, see [z/OS Communications Server: IP User's Guide and Commands](#).
- If AliasFile is specified, you might need to consider setting a reasonable value for MaxAliasRecursion to avoid excessive searches.

MaxAliasRecursion

Defines the maximum recursive search depth for recipients in the AliasFile. Valid values are in the range 1 - 65535. The default value is 10.

MaxRecipientsPerMessage

Defines the maximum recipients per mail message. Valid values are in the range 0 - 2000. If the value 0 is specified, the value 2000 is used. The default value is 2000.

IgnoreDots

Treat any line that contains only a single period as ordinary text, not as an EOF indicator when specified as IgnoreDots, IgnoreDots=True, IgnoreDots=T, or IgnoreDots=Y.

W statement

The W statement is an optional statement.

Defines the CSSMTP external writer name, which is used by CSSMTP as the selection criteria for the created JES spool data set. For more information about the CSSMTP configuration statement "ExtWrtName", see ["ExtWrtName statement" on page 1252](#).

Chapter 26. TIMED daemon

The TIMED daemon is used to provide the time in response to UDP requests. TIMED gives the time in seconds since midnight January 1, 1900. You can start TIMED from the z/OS shell or as a started procedure.

This topic contains the following information:

- [“Starting TIMED from z/OS” on page 1289](#)
- [“Starting TIMED as a procedure” on page 1289](#)

Requirement: TCP/IP must be started prior to starting TIMED.

Guideline: TIMED is different from the TIME daemon available as an internal daemon of INETD. INETD cannot be used to start and perform as a listener for TIMED.

Starting TIMED from z/OS

TIMED is installed in the /usr/lpp/tcpip/sbin/ directory.

To start the TIMED server from the command line, type the timed command as follows:

```
timed [-l] [-p port]
```

The following parameters used for the timed command:

-l

Logs all the incoming requests and responses to the system log. Logged information includes the IP address of the requester.

-p port

Uses the specified port. You can specify the port in which requests are to be received.

Starting TIMED as a procedure

The following sample shows how to start TIMED as a procedure:

```
//TIMED    PROC
//*
//* 5694-A01 (C) Copyright IBM Corp. 1997, 2002
//* Licensed Materials - Property of IBM
//* This product contains "Restricted Materials of IBM"
//* All rights reserved.
//* US Government Users Restricted Rights -
//* Use, duplication or disclosure restricted by
//* GSA ADP Schedule Contract with IBM Corp.
//* See IBM Copyright Instructions.
//*
//* Function: Time server start procedure
//* SMP/E distribution name: EZATTMDP
//*
//TIMED    EXEC PGM=TIMED,REGION=0K,TIME=NOLIMIT,
//          PARM='POSIX(ON),ALL31(ON),TRAP(OFF)/'
//*STEPLIB DD DISP=SHR,DSN=TCP.SEZALOAD,
//*          VOL=SER=,UNIT=
//SYSPRINT DD SYSOUT=*,DCB=(RECFM=F,LRECL=132,BLKSIZE=132)
//SYSIN    DD DUMMY
//SYSERR   DD SYSOUT=*
//SYSOUT   DD SYSOUT=*,DCB=(RECFM=F,LRECL=132,BLKSIZE=132)
//CEEDUMP  DD SYSOUT=*
//SYSABEND DD SYSOUT=*
//          PEND
```

Figure 51. Starting TIMED as a procedure

Chapter 27. SNTP daemon

You can start the SNTP daemon (SNTPD) from the z/OS shell or as a started procedure.

This topic contains the following information:

- [“Starting SNTPD from the z/OS UNIX shell” on page 1291](#)
- [“Starting SNTPD as a procedure” on page 1291](#)

Rule: TCP/IP must be started prior to starting SNTPD.

SNTPD uses 123 as the default UDP port. When the low number UDP ports are restricted (RESTRICTLOWPORTS parameter was specified on the UDPCONFIG profile statement for the TCP/IP stack), reserve the port used by SNTPD by specifying a PORT profile statement with the port number and the SNTPD started procedure name. To further restrict access to the SNTPD port, specify the SAF parameter on the PORT profile statement. See [“PORT statement” on page 207](#) for more information.

Restriction: SNTPD cannot be started from INETD.

Starting SNTPD from the z/OS UNIX shell

SNTPD is installed in the /usr/sbin/sntpd directory.

To start the SNTP server from the z/OS shell command line, type `sntpd &` on the command line. This starts sntpd and sends it to the background.

The following optional parameters are used for the sntpd command:

-d

Enables debugging. Debug messages go to syslogd daemon.

-df *pathname*

Enables debugging. Debug messages go to specified file location. The maximum length of the file name is the value of the z/OS XL C/C++ PATH_MAX constant.

-pf *pathname*

Specifies z/OS UNIX path for process ID file. The maximum length of the path name is the value of the z/OS XL C/C++ PATH_MAX constant, minus the length of the following:

- The last forward slash, '/', before the file name, if the path does not end in a forward slash.
- The length of the file name, sntpd.pid.

-b *nnnnn*

Acts in broadcast mode. This parameter sends local broadcasts on all interfaces every *nnnnn* seconds. The valid range for **-b** is 1 - 16284.

-m *nnnnn*

Acts in multicast mode. Sends multicast updates (TTL=1) on all interfaces every *nnnnn* seconds. The valid range for **-m** is 1 - 16284.

-s *n*

Use *n* as the stratum level in all replies sent by the server. The valid range for *n* is 1 - 15. If **-s** is not specified or an invalid value is specified, the default stratum level of 1 is used. The stratum level indicates the relative accuracy of the local clock compared to the clocks of other SNTP servers in the network. The value 1 is the most accurate and 15 is the least accurate.

Guideline: The SNTP server always responds to client requests (unicast mode), regardless if **-b** or **-m** start options are specified.

Starting SNTPD as a procedure

The following sample [shipped as SEZAINST(SNTPD)] shows how to start SNTPD as a procedure:

```

//SNTPD    PROC
//*
//* Sample procedure for the Simple Network Time Protocol (SNTP)
//*
//* z/OS Communications Server Version 1 Release 13
//* SMP/E Distribution Name: SEZAINST(EZASNPRO)
//*
//* Copyright:    Licensed Materials - Property of IBM
//*              5650-ZOS
//*              Copyright IBM Corp. 2002, 2015
//*
//* Status:      CSV2R2
//*
//SNTPD     EXEC PGM=SNTPD,REGION=4096K,TIME=NOLIMIT,
//          PARM='/ -d'
//SYSPRINT DD SYSOUT=*,DCB=(RECFM=F,LRECL=132,BLKSIZE=132)
//SYSIN    DD DUMMY
//SYSERR   DD SYSOUT=*
//SYSOUT   DD SYSOUT=*,DCB=(RECFM=F,LRECL=132,BLKSIZE=132)
//CEEDUMP  DD SYSOUT=*
//SYSABEND DD SYSOUT=*
//*

```

Figure 52. Starting SNTPD as a procedure

Chapter 28. Remote execution server

This topic discusses the TSO remote execution server and contains the following information:

- “Remote execution server cataloged procedure (RXPROC)” on page 1293
- “RXUEXIT user exit sample” on page 1297
- “z/OS remote execution server” on page 1299

The TSO remote execution server enables TSO commands to be submitted from a remote host and executed on z/OS.

Remote execution server cataloged procedure (RXPROC)

The following shows the Remote execution cataloged procedure (RXPROC):

```
//RXSERVE PROC MODULE='RSHD',
//      EXIT=,

```

Figure 53. Remote execution cataloged procedure (RXPROC)

Remote execution server parameters

The system parameters required by the Remote Execution server are passed by the PARM operand of the EXEC statement in the Remote Execution cataloged procedure. Update the following parameters as required by your installation:

EX= or EXIT=

Name of a user exit routine to inspect and alter JOB and EXEC parameters prior to submission of TSO batch jobs initiated by remote commands.

IPV6=

Y or N, indicating whether the server should attempt communication over an IPv6 network. If this option is not specified, the server attempts IPv6 communication. Specifying N for this option prevents IPv6-only clients from communicating with this server.

Tip: This option is useful for installations that have not migrated user exits to accommodate IPv6 addresses.

PHR= or PHRASE=

Y or N indicating whether the server should support a password phrase greater than 16 characters. If this parameter is not specified or N is specified, the server supports a password size of 16 characters. If Y is specified, the server supports a password phrase size of 100 characters.

Guidelines:

The password phrase value supplied by the client might be enclosed in single quotation marks. The total length of the password phrase when enclosed in single quotation marks is limited to 102 characters.

Restrictions:

The password phrase value supplied by the client must not contain the C programming language escape sequence (examples: \0, \r, \t, etc.).

PRE= or PREFIX=

A four-character value used as the first four characters in the job name of jobs that are submitted. The remaining characters of the job name is a sequential number in the range of 1 - 9999.

PUR= or PURGE=

Y or N, indicating whether a job submitted by the server should be purged immediately after execution or held in the output queue.

TSO= or TSOPROC=

The name of the TSO batch procedure. The default is IKJACCNT. The name IKJACCNT can be modified in the exit routine specified with the EXIT parameter.

MSG= or MSGCLASS=

The MSGCLASS parameter for TSO batch jobs submitted to execute remote commands. The default is H, which points to a HELD output class.

Restrictions:

- This parameter must not be altered by the exit routine.
- For JES3 users, the HELD output class needs to be defined as a HELD output class for external writer.

TSC= or TSCCLASS=

The SYSOUT class for the SYSTSPRT DD statement for submitted jobs. The default is A.

Restriction: For JES3 users, the HELD output class needs to be defined as a HELD output class for external writer.

MAX= or MAXCONN=

The maximum number of open sockets at any one time. Usually, each client requires 2 sockets while the command is being processed and the output is being returned. The minimum acceptable value is 512. This is also the default.

TR= or TRACE=

The trace options that are to be in effect for the Remote Execution server.

Rule: If more than one trace parameter is specified, enclose the parameters in parentheses.

LOG

Specifies trace records written to SYSPRINT.

NOL= or NOLOG

Specifies no trace records written to SYSPRINT.

SEN= or SEND

Specifies trace records sent to the client.

NOS= or NOSEND

Specifies no trace records sent to the client.

CLI= or CLIENT=*client*

Specifies a specific client host for which trace records are to be produced.

ALLC= or ALLCLIENTS

Specifies that trace records are to be produced for all clients.

RE= or RESET

Sets the trace options to NOLOG, NOSEND, ALLCLIENTS.

SL= or SECLABEL=

Y or N, indicating whether the server should attempt to add a security label to the job card. If this option is not specified, the server attempts to add a security label to the job card. If Y is specified for this option, the server adds a security label (if one exists) to the job card following the message class parameter. For more information about the multilevel security environment and configuring z/OS Communications Server in that environment, see the multilevel security information in the [z/OS Communications Server: IP Configuration Guide](#).

Use the MODIFY command to dynamically change all but the following parameters:

- MAXCONN
- PREFIX
- IPv6
- SECLABEL

Tip: All parameters can now be abbreviated. For example, EXIT can be abbreviated to EX.

Guideline: It is suggested not enabling the MVRSHD server. The MVRSHD server supports the RSH and REXEC protocols which transfer user ID and password information in the clear. There is also the potential of weak authentication for RSH clients using RHOSTS.DATA datasets. This authentication method allows

remote command execution without requiring the RSH client to supply a password. IBM Health Checker for z/OS can be used to check whether the MVRSHD server is active and detect an RSH client attempting to use an RHOSTS.DATA dataset for authentication. For more details about IBM Health Checker, see [IBM Health Checker for z/OS User's Guide](#).

RXUEXIT user exit sample

The following user exit is shipped as a sample in the RXUEXIT member of the SEZAINST data set:

```
*****
*
*           Communications Server IP
*
* Name:      RXUEXIT
*
* SMP/E Distribution Name: EZAEBRXU
*
* Function:   This exit will add a CLASS parameter to the JOB
*             statement submitted by the REXECD server in CS/390.
*
* Copyright:  Licensed Materials - Property of IBM
*             "Restricted Materials of IBM"
*             5694-A01
*             Copyright IBM Corp. 1977, 2008
*             US Government Users Restricted Rights -
*             Use, duplication or disclosure restricted by
*             GSA ADP Schedule Contract with IBM Corp.
*
* Status:    CSV1R10
*
* Interface:  Parameter list (R1 points to it on entry):
*
*           +0: A pointer to a mixed AF_INET or AF_INET6 address
*               structure
*               +0: (2 bytes) Address Family AF_INET, or AF_INET6.
*               +2: (2 bytes) Server port.
*               +4: (4 or 16 bytes) Client AF_INET or AF_INET6 IP
*                   address.
*
*           +4: Pointer to JOB card parameters (up to 1024
*               characters, terminated by a X'00'). This may be
*               modified by the exit routine. It is set to
*               "userid USER=userid,[PASSWORD=passwd,
*               ]MSGCLASS=msgclass" at entry, where 'msgclass'
*               is as specified in the daemon parameters, and
*               and 'userid' and 'passwd' are as received from
*               the client.
*
*           +8: Pointer to EXEC card parameters (up to 256
*               characters, terminated by a X'00'). This may be
*               modified by the exit routine. It is set to the
*               procedure specified on the PROC parameter, or the
*               default IKJACCNT, at entry.
*
*           +C: Pointer to JES control buffer (up to 256 characters,
*               terminated by a X'00'). This may be modified by the
*               exit routine. The contents are inserted into the
*               JCL stream following the JOB card and before the
*               EXEC card.
*
*           The EXEC and JES buffer contents are written
*           directly to the internal reader without being parsed.
*           The buffer contents must provide line separation by
*           including a NL or CRLF as required.
*
* Logic:     The typical contents of the JOB statement buffer
*             are; userid,USER=userid,PASSWORD=password,
*             MSGCLASS=H,SECLABEL=seclabel
*
*           The JOB statement buffer is 1024 bytes in length.
*           The contents of the buffer are null terminated.
*
```

```

*           If the buffer contents are altered, the user must
*           ensure they are null terminated (one byte x'00')
*           and that the total length including termination
*           byte does not exceed the buffer length.
*
*           The JES control statement buffer is 256 bytes in
*           length and the contents are null terminated.
*
* Abends:    - none -
*
* Returncode: RC = 0

z/OS remote execution server

The z/OS UNIX System Services remote execution servers, orexecd and orshd, allow UNIX commands to be submitted from a remote host and executed on z/OS.

z/OS UNIX System Services REXECD command (orexecd)

The following syntax is used in the /etc/inetd.conf file to define the arguments used to invoke the orexecd command:

➔ orexecd -d -l -v -c -s -p ➔

The following options are supported:

- d**
Print debug information to syslogd.
- l**
Write each successful login to syslogd with the remote user, remote system, local user, and the command executed.
- v**
Write the title and ptf level to syslogd.
- c**
Write all messages in uppercase.
- s**
Invoke the remote shell as a login shell (that is, run /etc/profile and \$HOME/.profile).
- p**
Password phrase support for 100 character value.

Guidelines:

The password phrase value supplied by the client might be enclosed in single quotation marks. The total length of the password phrase when enclosed in single quotation marks is limited to 102 characters.

Restrictions:

The password phrase value supplied by the client must not contain the C programming language escape sequence (examples: \0, \r, \t, etc.).

z/OS UNIX System Services RSHD command (orshd)

The following command is used in the /etc/inetd.conf file to define the arguments used to invoke orshd:

➔ orshd -a -d -l -v -c -r ➔

➔ -s -p -k mechanism -e -m ➔

➔ -i -t ➔

The following options are supported:

- a**
Look up host name and check that the address and host name correspond.

- d**
Print debug information to syslogd.
- l**
Write each successful login to syslogd with the remote user, remote system, local user, and the command executed.
- v**
Write the title and ptf level to syslogd.
- c**
Write all messages in uppercase.
- r**
If a client passes a null password, invoke the `/usr/sbin/ruserok` user exit to authenticate the user ID.
- s**
Invoke the remote shell as a login shell (that is, run `/etc/profile` and `$HOME/.profile`).
- p**
Password phrase support for 100 character value.

Guidelines:

The password phrase value supplied by the client might be enclosed in single quotation marks. The total length of the password phrase when enclosed in single quotation marks is limited to 102 characters.

Restrictions:

The password phrase value supplied by the client must not contain the C programming language escape sequence (examples: `\0`, `\r`, `\t`, etc.).

-k mechanism

Specifies the authentication mechanism to be used to authenticate the client. Valid values for mechanism are KRB5 and GSSAPI.

- e**
Requires the client to encrypt the connection.

- m**
Require Kerberos5 clients to present a cryptographic checksum of initial connection information, such as the name of the user that the client is trying to access in the initial authenticator. This checksum provides additional security by preventing an attacker from changing the initial connection information. If this option is specified, older Kerberos5 clients that do not send a checksum in the authenticator is not able to authenticate to this server. This option is mutually exclusive with the **-i** option and is only valid if **-k KRB5** is specified.

If neither the **-m** or **-i** options are specified, checksums are validated if presented. Because it is difficult to remove a checksum from an authenticator without making the authenticator invalid, this default mode is almost as significant of a security improvement as **-m** if new clients are used. It has the additional advantage of backwards compatibility with some clients. Clients before Kerberos V5, Beta5, generate invalid checksums; if these clients are used, the **-i** option must be used.

- i**
Ignore authenticator checksums if provided. This option ignores authenticator checksum presented by current Kerberos clients to protect initial connection information; it is the opposite of **-m**. This option is provided because some older clients (particularly clients predating the release of Kerberos V5 Beta5, May 1995) present invalid checksums that prevent Kerberos authentication from succeeding in the default mode. This option is mutually exclusive with the **-m** option and is only valid if **-k KRB5** is specified.

- t**
Use this option to set the `KRB5_SERVER_KEYTAB` environment variable. If this environment variable is set, the Security Runtime uses a local instance of the Kerberos security server to decrypt service tickets instead of obtaining the key from a key table.

Requirement: The orshd application must have at least read access to the IRR.RUSERMAP resource in the FACILITY class in order to use this capability. For more information, see [z/OS Integrated Security Services Network Authentication Service Administration](#).

RSHD command (orshd) environment variables

Table 115 on page 1301 provides a list of environment variables used by RSHD command () that can be tailored to a particular installation.

Table 115. RSHD command (orshd) environment variables			
Environment variable	Server, Client or Command type application	Description	Specific coding rules (or a link to syntax)
_EUV_SVC_DBG_FILENAME	ORSHD	Specifies the fully qualified name of the file that receives debug messages. Debug messages are written to the file specified by the _EUV_SVC_STDOUT_FILENAME if this environment variable is not defined. If _EUV_SVC_STDOUT_FILENAME is not specified, debug messages are written to stdout.	Specifying debug (-d or -D option) and authentication (-k or -K) sets the variable to the value /etc/skrb/krb.log. If you want to allow the user-specified variable to be used, do not specify debug (-d or -D option).
_EUV_SVC_DBG_MSG_LOGGING	ORSHD	Specifies whether authentication trace records are generated when authentication is requested (-k or -K option). These trace records are stored in an internal wrap table. The following values can be specified: <ul style="list-style-type: none"> • 0 means do not generate trace records (this is the default) • 1 means generate trace records 	Specifying debug (-d or -D option) and authentication (-k or -K) sets the variable value to 1. If you want to allow the user-specified variable to be used, do not specify debug (-d or -D option).

Table 115. RSHD command (orshd) environment variables (continued)

Environment variable	Server, Client or Command type application	Description	Specific coding rules (or a link to syntax)
_EUV_SVC_DBG_TRACE	ORSHD	<p>Specifies whether authentication trace records are generated when authentication is requested (-k or -K option). These trace records are stored in an internal wrap table. The following values can be specified:</p> <ul style="list-style-type: none"> • 0 means do not generate trace records (this is the default) • 1 means generate trace records 	<p>Specifying debug (-d or -D option) and authentication (-k or -K) sets the variable value to 1. If you want to allow the user-specified variable to be used, do not specify debug (-d or -D option).</p>
KRB5_SERVER_KEYTAB	ORSHD	<p>Specifies whether the Security Runtime uses a local instance of the Kerberos security server to decrypt service tickets instead of obtaining the key from a key table. The default is to obtain the key from a key table.</p> <ul style="list-style-type: none"> • 0 means obtain the key from a key table • 1 means use a local instance 	<p>Specifying the -t or -T option sets the variable to 1.</p>

Appendix A. Translation tables

This topic contains the following information:

- “SBCS translation table hierarchy” on page 1303
- “SBCS country or region translation tables” on page 1307
- “DBCS translation table hierarchy” on page 1310

TCP/IP Services uses translation tables to convert transmitted data from EBCDIC to ASCII. Because these tables do not always include all the desired characters, TCP/IP allows you to create and customize tables without having to recompile source code. Translation tables are stored in binary form on disk. TCP/IP provides standard tables that are used as the default if you do not customize your own.

TCP/IP Services used the following types of translation tables:

- Single-byte character set (SBCS) translation tables are used for single-byte characters.
- Double-byte character sets (DBCS) translation tables are used for converting double-byte characters. DBCS translation tables are required for character sets such as Japanese Kanji, which contains too many characters to represent using single-byte codes. SBCS translation tables provide mappings for a maximum of 256 characters. DBCS translation tables can provide up to a theoretical maximum of 65 535 character mappings; however, DBCS character sets usually contain less than this number.

The FTP program provides an FTP.DATA statement, DUMP 81, that is available for tracing the translate tables. When set on, 256 bytes of each translate table can be traced as follows:

- When the FTP STAT command is entered, the translate tables being used by the server for the control and data connection is traced. When the FTP LOCSTAT command is entered, the translate tables being used by the client is traced.
- When an FTP command is entered to change the translate table, the new table is traced. If the change is entered as a locsite command then it is traced by the client. If the change is entered as a site command, then it is traced by the server.

See *z/OS Communications Server: IP User's Guide and Commands* FTP DUMP command information for instructions on entering the command or adding it to FTP.DATA for the server and client. For all trace entries, if the trace is on the server side, it is written to syslogd. Where the client trace entries are written depends on how the client is run. If it is TSO interactive or run in OEM, the trace appears on the console. If it is a batch job, it is in the job output, and if it is being used by Rexx, it is in the Rexx output.

The FTP program also provides a multi-byte character set (MBCS) to support the Chinese standard GB18030. This support is provided by **iconv** with code page IBM-5488; it does not allow for customized tables. See Chapter 14, “File Transfer Protocol,” on page 587 for a description of the ENCODING and MBDATACONN statements that define this support for FTP. Also, see *z/OS Communications Server: IP User's Guide and Commands* for information about how to use the LOCSITE and SITE subcommands to specify ENCODING and MBDATACONN values.

The following topics describe how to create and customize both SBCS and DBCS translation tables and explain how they are used by the programs in TCP/IP Services.

SBCS translation table hierarchy

Different programs look for special translation tables to use. The program chooses one of the customized tables, as described in [Table 116 on page 1304](#). The program first searches for a customized table that you have built. If the program fails to find one of the customized tables, it uses the default table supplied in *hlq.STANDARD.TCPXLBIN*. [Table 116 on page 1304](#) provides the customized translation tables and default table names for the programs.

Guideline: FTP server and FTP client optionally use **iconv** instead of the external tables for single-byte conversion. The use of **iconv** is specified in FTP.DATA or by SITE/LOCSITE commands.

Table 116. SBCS translation table hierarchy

Program	Customized translation tables	Default translation table
FTP client control connection when no TRANSLATE parameter is specified on the ftp command	<ol style="list-style-type: none"> 1. EXTENSIONS UTF8 2. Data set specified in the CTRLCONN configuration statement in FTP.DATA 3. Data set specified in the CCTRANS configuration statement in FTP.DATA 4. user_id.FTP.TCPXLBIN 5. hlq.FTP.TCPXLBIN 6. user_id.STANDARD.TCPXLBIN 7. hlq.STANDARD.TCPXLBIN 8. 7-bit ASCII - (ISO8859-1 for the network code page and IBM-1047 for the file system code page) 9. FTP internal 7-bit tables 	The default should be number 8 for most all cases.
FTP client data connection when no TRANSLATE parameter is specified on the ftp command	<ol style="list-style-type: none"> 1. Data set specified in the SBDATACONN configuration statement in FTP.DATA 2. Data set specified in the SBTRANS configuration statement in FTP.DATA 3. user_id.FTP.TCPXLBIN 4. hlq.FTP.TCPXLBIN 5. user_id.STANDARD.TCPXLBIN 6. hlq.STANDARD.TCPXLBIN 7. The same translation tables established for the control connection 	The default is number 7.
FTP client when TRANSLATE parameter is specified on the ftp command for both control connections and data connections ¹	<ol style="list-style-type: none"> 1. If the client is started in the z/OS UNIX System Services shell: \$HOME/data_set.tcpxlbina 2. user_id.data_set.TCPXLBIN 3. hlq.data_set.TCPXLBIN 	There is no default.

Table 116. SBCS translation table hierarchy (continued)

Program	Customized translation tables	Default translation table
FTP server control connections	<ol style="list-style-type: none"> 1. EXTENSIONS UTF8 2. Data set specified in the CTRLCONN configuration statement in FTP.DATA 3. Data set specified in the CCXLATE configuration statement in FTP.DATA 4. jobname.SRVRFTP.TCPXLBIN 5. hlq.SRVRFTP.TCPXLBIN 6. jobname.STANDARD.TCPXLBIN 7. hlq.STANDARD.TCPXLBIN 8. 7-bit ASCII - (ISO8859-1 for the network code page and IBM-1047 for the file system code page) 9. FTP internal 7-bit tables 	The default should be number 8 for most all cases.
FTP server data connections	<ol style="list-style-type: none"> 1. Data set specified with DD: SYSFTSX in the FTP start procedure 2. Data set specified in the SBDAACONN configuration statement in FTP.DATA 3. Data set specified in the XLATE configuration statement in FTP.DATA 4. jobname.SRVRFTP.TCPXLBIN 5. hlq.SRVRFTP.TCPXLBIN 6. jobname.STANDARD.TCPXLBI 7. hlq.STANDARD.TCPXLBIN 8. The same translation tables established for the control connection 	The default is number 8.
LPR Client	<ol style="list-style-type: none"> 1. user_id.LPR.TCPXLBIN 2. hlq.LPR.TCPXLBIN 3. user_id.STANDARD.TCPXLBIN 	hlq.STANDARD.TCPXLBIN
LPR Client (TRANSLATE)	<ol style="list-style-type: none"> 1. user_id.data_set.TCPXLBIN 2. hlq.data_set.TCPXLBIN 3. user_id.LPR.TCPXLBIN 4. hlq.LPR.TCPXLBIN 5. user_id.STANDARD.TCPXLBIN 	hlq.STANDARD.TCPXLBIN
LPD Server	jobname.data.STANDARD.TCPXLBIN	hlq.STANDARD.TCPXLBIN
LPD Server (TRANSLATE)	<ol style="list-style-type: none"> 1. jobname.data_set.TCPXLBIN 2. hlq.data_set.TCPXLBIN 	None. Printer services cannot be used.
PORTMAP	<ol style="list-style-type: none"> 1. user_id.STANDARD.TCPXLBIN 2. jobname.STANDARD.TCPXLBIN 	hlq.STANDARD.TCPXLBIN
REXEC	user_id.STANDARD.TCPXLBIN	hlq.STANDARD.TCPXLBIN

Table 116. SBCS translation table hierarchy (continued)

Program	Customized translation tables	Default translation table
Telnet Client	<ol style="list-style-type: none"> 1. <i>user_id</i>.TELNET.TCPXLBIN 2. <i>hlq</i>.TELNET.TCPXLBIN 3. <i>user_id</i>.STANDARD.TCPXLBIN 	<i>hlq</i> .TELNET.TCPXLBIN
Telnet Client (TRANSLATE)	<ol style="list-style-type: none"> 1. <i>user_id.data_set</i>.TCPXLBIN 2. <i>hlq.data_set</i>.TCPXLBIN 	None. Program Halts.

Notes:

1. *jobname* is the name specified either on the PROC or JOB statement.
2. *user_id* is the ID of the user who issued the command.
3. *data_set* is the name entered on the TRANSLATE parameter for the program. See [z/OS Communications Server: IP User's Guide and Commands](#) for information about specifying the TRANSLATE parameter for the required program.
4. High Level Qualifier (*hlq*) specified in the TCPIP.DATA configuration statement, DATASETPREFIX.

The Telnet client requires translation tables that are different from the default table *hlq*.STANDARD.TCPXLBIN. Customized translation tables for Telnet clients are provided in the install libraries as *hlq*.TELNET.TCPXLBIN and *hlq*.TELNETSE.TCPXLBIN. If these data sets are not found, the Telnet client uses the default table.

Telnet (for Linemode) uses **iconv** services with the CODEPAGE statement in the TELNETPARMS block to specify country and region translation tables. TCPXLBIN translation tables are not used. If CODEPAGE is in error or not specified, see “CODEPAGE statement” on page 501 for default values used. If custom code pages are required, see the information about globalization in the [z/OS XL C/C++ Programming Guide](#) for details about how to create your own conversions.

Customizing SBCS translation tables

All SBCS translation table members contain two tables. The first table is used to translate from ASCII to EBCDIC. The second table is used to translate from EBCDIC to ASCII.

To read the translation tables, find the row for the first hex digit (1) and the column for the second hex digit (2). The point where the row and column intersect is the translation value.

For example, to find the EBCDIC translation for the ASCII character A7, find row A0 (3) and column 07 (4) in “ASCII-to-EBCDIC table” on page 1306. The point where row A0 and column 07 intersect shows a value of X'7D', so the ASCII character X'A7' is translated to X'7D' in EBCDIC.

To customize the translation table, alter the translate value where the row and column intersect to the new value.

You can edit and modify translation table members in the SEZATCPX data set.

ASCII-to-EBCDIC table

The samples shown in [Figure 55 on page 1307](#) and [Figure 56 on page 1307](#) are shipped as the *hlq*.STANDARD.TCPXLBIN compiled translation table, and unless modified, is used for EBCDIC-to-ASCII or ASCII-to-EBCDIC translation.

¹ Do not use the TRANSLATE option for the FTP client if the SBCS table you need for data transfer does not support standard encodings for the portable character set. Such a translation table can adversely affect the EBCDIC to ASCII conversion of commands sent over the control connection.

Figure 56. EBCDIC-to-ASCII translation table

Syntax rules for SBCS translation tables

The following syntax rules apply to SBCS translation tables:

- Blanks are used only as delimiters for readability purposes.
- Information to the right of a semicolon (;) is a comment.

SBCS country or region translation tables

Rather than customize the table in SEZATCPX(STANDARD), you can use the following translation table members, which are included with the code.

These translation table members are in the same format as that used in SEZATCPX(STANDARD). To use these table members, you must convert them to binary format using CONVXLAT and store the resulting binary tables in an appropriate data set within the SBCS translation table hierarchy. (See “SBCS translation table hierarchy” on page 1303.) For more information about using the TSO CONVXLAT command, see “Using TSO CONVXLAT to convert translation tables to binary” on page 1314.

The editable translation tables used by the Telnet client application are members of the SEZATELX data set and are derived from the identified code pages. The editable tables used by other applications, such as FTP, are members of the SEZATCPX data set.

The following members can be used by both Telnet client and non-Telnet SBCS applications such as FTP, and so on. They are found in both SEZATELX and SEZATCPX.

Restriction: Identically named members in the two data sets are **not** the same.

Table 117. Translation table members for Telnet client and non-Telnet SBCS applications

Member name	Description	Code page
AUSGER *	Austrian-German code page	850<->273

ISO-8 and IBM PC interpretations for ASCII and EBCDIC code points

The tables in the SEZATCPX data set use the ISO-8 interpretations for certain ASCII code points. These code points are mapped to EBCDIC code points, as shown in Table 119 on page 1309.

Table 119. ISO-8 interpretations for certain ASCII and EBCDIC code points

ASCII code point	EBCDIC code point	ISO-8 interpretation
X'1A'	X'3F'	SUB (substitution character)
X'1C'	X'1C'	IFS (interchange file separator)
X'7F'	X'07'	DEL (delete character)

If you want to use IBM PC interpretations for these code points, you can modify your table, as shown in Table 120 on page 1310:

Table 120. IBM PC interpretations for certain ASCII and EBCDIC code points

ASCII code point	EBCDIC code point	IBM PC interpretation
X'1A'	X'1C'	IFS (interchange file separator)
X'1C'	X'07'	DEL (delete character)
X'7F'	X'3F'	SUB (substitution character)

DBCS translation table hierarchy

Table 121 on page 1310 describes the search order used by certain programs when they are configured to load one or more DBCS translation tables.

If the customized DBCS translation tables are not found, then the default table data sets provided with the install libraries are used. If the default tables cannot be read, then error messages are issued, and the required DBCS conversion is unavailable for the program.

Table 121. DBCS translation table hierarchy

Program	Option	Customized translation tables	Default translation table
FTP client	Hangeul	1. <i>user_id</i> .FTP.TCPHGBIN 2. <i>hlq</i> .FTP.TCPHGBIN 3. <i>user_id</i> .STANDARD.TCPHGBIN	<i>hlq</i> .STANDARD.TCPHGBIN
FTP client	Kanji	1. <i>user_id</i> .FTP.TCPKJBIN 2. <i>hlq</i> .FTP.TCPKJBIN 3. <i>user_id</i> .STANDARD.TCPKJBIN	<i>hlq</i> .STANDARD.TCPKJBIN
FTP client	SChinese	1. <i>user_id</i> .FTP.TCPSCBIN 2. <i>hlq</i> .FTP.TCPSCBIN 3. <i>user_id</i> .STANDARD.TCPSCBIN	<i>hlq</i> .STANDARD.TCPSCBIN
FTP client	TChinese	1. <i>user_id</i> .FTP.TCPCHBIN 2. <i>hlq</i> .FTP.TCPCHBIN 3. <i>user_id</i> .STANDARD.TCPCHBIN	<i>hlq</i> .STANDARD.TCPCHBIN
FTP client	Hangeul and TRANSLATE *	1. <i>user_id.data_set</i> .TCPHGBIN 2. <i>hlq.data_set</i> .TCPHGBIN 3. <i>user_id</i> .STANDARD.TCPHGBIN	<i>hlq</i> .STANDARD.TCPHGBIN
FTP client	Kanji and TRANSLATE *	1. <i>user_id.data_set</i> .TCPKJBIN 2. <i>hlq.data_set</i> .TCPKJBIN 3. <i>user_id</i> .STANDARD.TCPKJBIN	<i>hlq</i> .STANDARD.TCPKJBIN
FTP client	SChinese and TRANSLATE *	1. <i>user_id.data_set</i> .TCPSCBIN 2. <i>hlq.data_set</i> .TCPSCBIN 3. <i>user_id</i> .STANDARD.TCPSCBIN	<i>hlq</i> .STANDARD.TCPSCBIN

Table 121. DBCS translation table hierarchy (continued)

*: See “Usage notes for the TRANSLATE option for the FTP client” on page 1312

Notes:

1. *jobname* is the name specified either on the PROC or JOB statement.
2. *user_id* is the ID of the user who issued the command.
3. *data_set* is the name entered on the TRANSLATE parameter for the program. See the [z/OS Communications Server: IP User's Guide and Commands](#) for information about specifying the TRANSLATE parameter for the required program.

Usage notes for the TRANSLATE option for the FTP client

- To use the TRANSLATE option to load and use a customized DBCS translation table for the FTP client, an SBCS table data set must also exist for the *data_set_name* chosen with the TRANSLATE option.

If the SBCS table data set does not exist, the FTP request fails even if a valid DBCS table data set using that name exists.

- **ATTENTION:** Do not use the TRANSLATE option for the FTP client if the SBCS table you need for data transfer does not support standard encodings for the portable character set. Such a translation table can adversely affect the EBCDIC to ASCII conversion of commands sent over the control connection.

For information about using FTP.DATA to specify different SBCS tables for control and data connections, see [z/OS Communications Server: IP User's Guide and Commands](#).

If you require a local DBCS translation table, you must name it in correlation with the standard client search order. For example, if you had a custom Kanji table you could name it *user_id*.FTP.TCPKJBIN.

Telnet 3270 DBCS transform mode codefiles

The binary translation table code files used by Telnet 3270 DBCS transform mode do not use a search order hierarchy. If the DD statement is not specified, or the codefiles are not present, 3270 DBCS transform mode is disabled.

Restriction: The codefile members must reside in a data set pointed to by the TNDBCSXL DD statement in the TCPIPROC cataloged procedure.

Steps for customizing DBCS translation tables

You can find the DBCS translation tables in the installation libraries in both editable source and binary form. The Kanji, Hangeul, Traditional Chinese and Simplified Chinese DBCS editable source members reside in the SEZADBCX data set. The standard binary members reside in the STANDARD.TCPKJBIN for Kanji, the STANDARD.TCPHGBIN for Hangeul, the STANDARD.TCPCHBIN for Traditional Chinese, and the STANDARD.TCPSCBIN for Simplified Chinese. These data sets contain binary tables that are used by the FTP server, FTP client, LPR client, and LPD server programs. The binary codefiles used by Telnet 3270

DBCS transform mode reside in the SEZAXLD2 data set. The binary tables and codefiles can be created from the same editable source, using the CONVXLAT program.

Procedure

Perform the following steps to customize a DBCS translation table:

1. Make a copy of the editable source data set.
2. Modify the editable source as required.
3. Run the CONVXLAT program with the modified editable source as input.
4. Install the resulting customized binary table or codefiles in the DBCS translation table hierarchy for the required program.

Results

The editable source data sets contain two column pairs for each code page. The first column pair specifies double-byte EBCDIC-to-ASCII code point mappings for the indicated code page. The second column pair specifies double-byte ASCII-to-EBCDIC code point mappings for the indicated code page.

Existing code-point mappings can be changed by overwriting the existing hexadecimal code. Code points that are not defined in the target code page and are within the valid range for the code page are mapped to the default substitution character in the target code page. The default substitution characters are shown as (sub: xxxx) in the source tables in this topic.

The editable source format specifies EBCDIC-to-ASCII and ASCII-to-EBCDIC mappings separately. When adding or changing a code-point mapping, care should be taken to modify both mappings for the code point. If, for example, a new mapping is added for EBCDIC-to-ASCII only, the ASCII-to-EBCDIC mapping for that code-point is the default substitution character.

DBCS country or region translation tables

The translation table source members in Table 122 on page 1313 are in the SEZADBCX data set. They are used by all applications that support DBCS. See [“Using TSO CONVXLAT to convert translation tables to binary” on page 1314](#) for more information about using the TSO CONVXLAT command.

Requirement: If you modify these table members, you must convert them to binary format using CONVXLAT and store the modified binary data set in an appropriate data set within the DBCS translation table hierarchy.

Table 122. Translation table members for DBCS applications

Member name	Description	Code page
EZACHLAT (Taiwan DBCS)	TChinese Big5	0927<->0835 0947<->0835
EZAHGLAT (Korea DBCS)	Hangeul KSC5601	0926<->0834 0951<->0834
EZAKJLAT (Japan DBCS)	PC to host code page SJISKANJI 0941 at 1978	PC<->0300
EZAKJ941 (Japan DBCS)	PC to host code page SJISKANJI at 0941 at 1995 level	PC<->0300
EZASCLAT (People's Republic of China DBCS)	Schinese	1380<->0837

Syntax rules for DBCS translation tables

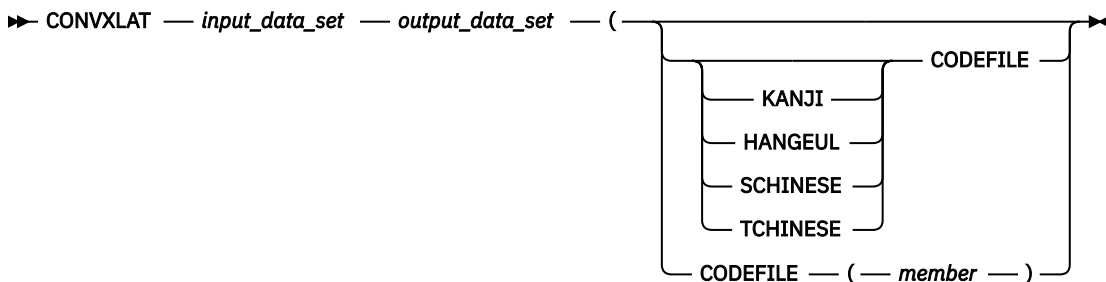

Observe the following rules for DBCS translation tables:

- Comments can be included in the editable data set, either on a separate line or at the end of a line. Comments must start with a semicolon (;).
- Code-point mappings in the data set are position dependent. The first non-comment line for the DBCS tables in the data set is used to establish the column position of the code point mappings, and must contain a conversion pair for each code page. Any conversion pairs on following lines must use the same column positions.
- It is permissible to leave blanks for code-point mappings after the first line in the DBCS area. For example, if a line contains only one conversion pair, the column position is used to determine which code page it refers to.
- The first column of each code page column pair (that is, the code index), must be in ascending numeric order. Any gaps in the ascending order is filled with the default substitution character in the binary table created by CONVXLAT.

Using TSO CONVXLAT to convert translation tables to binary

The TSO CONVXLAT command converts a table from editable text to binary. CONVXLAT can be used to convert both SBCS and DBCS table source data sets.

The syntax of the CONVXLAT command is:

The parameters of the CONVXLAT command are:

input_data_set

Specifies the source data set name to be converted. The data set name must be enclosed in quotation marks if fully qualified; otherwise the TSO user ID is appended as a prefix.

output_data_set

Specifies the destination data set name created by the conversion. The data set name must be enclosed in quotation marks if fully qualified; otherwise the TSO user ID is appended as a prefix.

Rule: If CODEFILE is also specified, then *output_data_set* must specify a previously allocated partitioned data set. Multiple codefile members are placed in the partitioned data set.

The data set should be allocated using the following parameters:

Organization:	P0
Record format:	VB
Record length:	5124
Block size:	8800
1st extent blocks:	156
Secondary blocks:	10

KANJI

Specifies that the tables being converted are the Japanese DBCS translation tables.

HANGEUL

Specifies that the tables being converted are the Korean Standard DBCS translation tables.

SCHINESE

Specifies that the table being converted is the Simplified Chinese DBCS translation table.

TCHINESE

Specifies that the table being converted is the Traditional Chinese DBCS translation table.

CODEFILE

Specifies that the selected table is converted to multiple codefiles for use in Telnet 3270 DBCS transform mode. The selected table must be DBCS translation table.

CODEFILE(*member*)

Specifies that the selected SBCS table is converted to two codefiles: ASCII_To_EBCDIC and EBCDIC_To_ASCII. The member names in the output PDS are *member*ATE and *member*ETA. The following names are possible member names:

J8E

JIS 8 Bit English

J8K

JIS 8 Bit Katakana

A8E

8 Bit English

A8K

8 Bit Katakana

SJDCE

DEC English SBCS

SJDCK

DEC Katakana SBCS

SJECE

Japanese EUC English SBCS

SJECK

Japanese EUC Katakana SBCS

SKSH

Korean KSC 5601 SBCS

SHAN

Hangeul SBCS

STCH

Traditional Chinese SBCS

SBG5

Big-5 SBCS

SSCH

Simplified Chinese SBCS

If no optional parameters are specified, the input data set is assumed to contain an SBCS translation table.

CONVXLAT examples

This topic contains CONVXLAT examples.

Running CONVXLAT in BATCH

The following examples are of running CONVXLAT in batch.

Run the CONVXLAT program directly in a job.

```
//S00100    EXEC PGM=CONVXLAT,  
//          PARM='''TCP3AS.SEZATCPX(FRENCH)''' USER3.STANDARD.TCPXLBIN'''  
//SYSPRINT DD SYSOUT=*  
//SYSIN    DD DUMMY,BLKSIZE=80
```

Run the CONVXLAT program by using TSO batch.

```
//TS0CNVXL JOB ,CLASS=A,MSGCLASS=A,MSGLEVEL=(1,1),USER=USER200,
//      PASSWORD=xxxxxx
//EXEC EXEC PGM=IKJEFT1B,TIME=(0,50),REGION=3096K
//*
//SYSTSPRT DD SYSOUT=*
//SYSPRINT DD SYSOUT=*
//SYSIN    DD DUMMY
//SYSTSIN DD *
convxlat 'TCP3AS.SEZATCPX(FRENCH)' +
        'user3.standard.tcpplbin'
/*
```

SBCS binary table

The following example shows the creation of an SBCS binary table from user-provided editable text.

```
convxlat sbcs.source standard.tcpplbin
READY
```

French Telnet client SBC

The following example shows the creation of a French Telnet Client SBCS binary table for user ID user30 from the product provided editable text:

```
convxlat 'tcpip.v3r2.sezatelx(french)' 'user30.telnet.tcpplbin'
READY
```

Korean KSC5601 SBCS and DBCS

The following example shows the creation of a Korean KSC5601 SBCS and DBCS binary table from the product-provided editable text. These tables can be used by FTP, LPR and LPD .

```
convxlat 'tcpip.v3r2.sezatepx(kor1088)' 'tcpip.v3r2.standard.tcpplbin'
READY
convxlat 'tcpip.v3r2.sezadbcx(ezahglat)' 'tcpip.v3r2.standard.tcphgbin' (hangeul)
READY
```

Big-5 and traditional Chinese

The following example shows the creation of Big-5 and Traditional Chinese SBCS and DBCS codefiles for use by the Telnet 3270 DBCS Transform facility:

```
convxlat 'tcpip.v3r2.sezatelx(TAI1114)' 'tcpip.v3r2.sezaxld2' (codefile(sbg5))
READY
convxlat 'tcpip.v3r2.sezatelx(TAI0904)' 'tcpip.v3r2.sezaxld2' (codefile(stch))
READY
convxlat 'tcpip.v3r2.sezadbcx(ezachlat)' 'tcpip.v3r2.sezaxld2' (tchinese codefile
EZA0652I Current code set is "TCHETA"
EZA0652I Current code set is "TCHATE"
EZA0652I Current code set is "BG5ETA"
EZA0652I Current code set is "BG5ATE"
READY
```

Japanese SBCS (CP 1041) and DBCS

The following example shows the creation of a Japanese SBCS (CP 1041) and DBCS binary table from the product provided editable text. These tables can be used by FTP, LPR and LPD.

```
convxlat 'tcpip.v3r2.sezatepx(JPNKANA)' 'tcpip.v3r2.standard.tcpplbin'
READY
convxlat 'tcpip.v3r2.sezadbcx(ezakjlat)' 'tcpip.v3r2.standard.tcpkjbini' (kanji)
READY
```

Japanese SBCS and DBCS codefiles

The following example shows the creation of Japanese SBCS and DBCS codefiles for use by the Telnet 3270 DBCS Transform facility:

```
convxlat 'tcpip.v3r2.sezatelx(J8E)' 'tcpip.v3r2.sezaxld2' (codefile(j8e)
READY
convxlat 'tcpip.v3r2.sezatelx(J8K)' 'tcpip.v3r2.sezaxld2' (codefile(j8k)
READY
convxlat 'tcpip.v3r2.sezatelx(A8E)' 'tcpip.v3r2.sezaxld2' (codefile(a8e)
READY
convxlat 'tcpip.v3r2.sezatelx(A8K)' 'tcpip.v3r2.sezaxld2' (codefile(a8k)
READY
convxlat 'tcpip.v3r2.sezatelx(SJECE)' 'tcpip.v3r2.sezaxld2' (codefile(sjece)
READY
convxlat 'tcpip.v3r2.sezatelx(SJECK)' 'tcpip.v3r2.sezaxld2' (codefile(sjeck)
READY
convxlat 'tcpip.v3r2.sezatelx(SJDCE)' 'tcpip.v3r2.sezaxld2' (codefile(sjdce)
READY
convxlat 'tcpip.v3r2.sezatelx(SJDCK)' 'tcpip.v3r2.sezaxld2' (codefile(sjdck)
READY

Appendix B. LDAP definition files

This topic contains the policy definition files that define the policy schema characteristics to an LDAP server.

These files show, respectively, the definitions of the various attributes that can be used to define policies, and the definitions of the object classes that contain these attributes. See [Chapter 16, “Policy Agent and policy applications,”](#) on page 819 and [z/OS Communications Server: IP Configuration Guide](#) for guidance about the different types of policies and examples of their usage.

Restriction: Not all of the object classes and attributes shown in the definition files are supported on z/OS. The LDAP schema is a superset of policy object classes and attributes needed for several different platforms. Only those object classes and attributes shown in [Chapter 16, “Policy Agent and policy applications,”](#) on page 819 are supported.

PAGENTAT sample

```
#
# pagent_at.conf
#
# This file contains a set of LDAP directory attributes for the
# Quality of Service (QOS) and Intrusion Detection System (IDS)
# policy objects defined with the LDAP server.
#

# objectClass attribute is used to associate an object with a class (see
# object class definition file for detail).
# This is a multi-valued attribute.

normal

# ibm-policyRuleEnabled attribute specifies an enumeration indicating
# whether a policy rule is administratively enabled, disabled, or
# enabled for debug mode. Note that the S/390 implementation treats
# enabled for debug the same as enabled.
# This is a single-valued attribute. The defined values for this
# attribute are 1 for enabled, 2 for disabled, and 3 for enabled for
# debug mode. Default is 1.
attribute      ibm-policyRuleEnabled                cis      policyRuleEnable        1
normal

# ibm-policyRuleConditionListType attribute specifies whether the list of policy
# conditions associated with this policy rule is in Disjunctive Normal Form
# (DNF - ORed groups/sets of ANDed conditions) or Conjunctive Normal Form
# (CNF - ANDed groups/sets of ORed conditions).
# This is a single-valued attribute. The defined values for this
# attribute are 1 for DNF, and 2 for CNF. Default is 1. Note that
# this attribute is only valid for complex rules.
attribute      ibm-policyRuleConditionListType      cis      policyRuleCondLT        1
normal

# ibm-policyRuleConditionList attribute specifies an unordered list of strings
# of the form:
#   ibm-policyRuleConditionList:group-number:< +|- >:dn
# indicating a set of policy conditions that determine when the policy rule
# is applicable/fired. The group-number specifies the group or set of
# the policy conditions, in which the referenced condition belongs.
# The < +|- > specifies if the condition is to be negated. The dn is
# the distinguished name of the referenced condition. This attribute
# applies to version 2 policies.
# This is a multi-valued attribute. Here is an example:
#   ibm-policyRuleConditionListType:1
#   ibm-policyRuleConditionList:1+:C1
#   ibm-policyRuleConditionList:1+:C2
#   ibm-policyRuleConditionList:2+:C3
#   ibm-policyRuleConditionList:2-:C4
# This is equivalent to: ( C1 AND C2 ) OR ( C3 AND (NOT C4) )
attribute      ibm-policyRuleConditionList          cis      policyRuleCondLi        256
normal

```

```

# ibm-policyRuleConditionListDN attribute specifies an unordered list of
# DN pointers indicating a set of policy conditions that determine when
# the policy rule is applicable/fired. This attribute contains the
# distinguished name of the referenced condition. This attribute
# applies to version 3 policies.
# This is a multi-valued attribute.
attribute      ibm-policyRuleConditionListDN          dn      policyRuleClistD      256
normal

# ibm-policyRuleActionList attribute is an unordered list of strings of the form:
#   ibm-policyRuleActionList:n:dn
# it specifies an ordered set of policy actions to be performed if the
# overall associated policy conditions of the corresponding policy rule
# evaluates to TRUE. The n value specifies the order of the actions
# to be executed. A value of 0 means "don't care". The dn is the
# distinguished name of the referenced action. Note that the S/390
# implementation executes only one action that is found to be most
# appropriate (e.g., action with scope of DataTraffic or Both for
# non-RSVP IP traffic). However, the actions are still ordered
# according to this attribute. If there are more actions than can be
# executed, the first one in the ordered list will be selected and the
# remaining ones will be ignored. This attribute applies to version
# 2 policies.
# This is a multi-valued attribute. Here is an example:
#   ibm-policyRuleActionList:1:DN-Action1
#   ibm-policyRuleActionList:2:DN-Action2
attribute      ibm-policyRuleActionList              cis      policyRuleActL      256

# ibm-applicationData attribute is used for content-based policy classification.
# This means the policy allows policy condition to include application
# data to be included in the evaluation process. It enables an application
# to assign different types of QoS treatments for different transactions
# (or streams of data) within a session. In S/390, only web URI (Universal
# Resource Identifier) is supported as application data and only when the
# web application server activates Fast Response Cache Accelerator (FRCA)
# function. This attribute is limited to 128 characters (longer data are
# silently truncated). The format of this attribute is as follows:
#   ibm-applicationData:<a character string>
# This is a single-valued attribute.
#   an example:
#       ibm-applicationData:/cat/purchase/info
attribute      ibm-applicationData          ces      applData          128
normal

# ibm-applicationPriority attribute is used for content-based policy
# classification. It allows an application to assign different
# priorities for different transactions (or streams of data) within a
# session. Valid values are as follows:
# 0 = Any application priority specified (default).
# 1 = EXPEDITED, 2 = HIGH, 3 = MEDIUM, 4 = LOW, 5 = BESTEFFORT.
# The format of this attribute is as follows:
#   ibm-applicationPriority:<an integer value>
# This attribute applies to version 3 policies.
# This is a single-valued attribute.
#   an example:
#       ibm-applicationPriority:3
attribute      ibm-applicationPriority      cis      applPriority      1
normal

# ibm-interface attribute is used for both ibm-policyRule and ibm-policyAction objects.
# For ibm-policyRule objects, it is used to limit the policy scope to specific
# inbound and outbound interfaces/subnets as IP packets traverse a network
# element (e.g., router). If both inbound and outbound interface values
# are specified in an ibm-interface attribute, it means the corresponding
# policy is to be applied to transit traffic that arrives on one interface
# and departs on another interface (e.g., traffic going through a router).
# From S/390 server's point of view, because our implementation of policy
# is as a host, a packet is destined to the server after it arrives on an
# inbound interface, whereas an outbound packet originates from the server
# and is sent on an outbound interface. As a result, if both inbound and
# outbound interface non-null values are specified together, the corresponding
# rule won't be mapped to any traffic since S/390 doesn't support policy as a
# routing node. Either an IPv4 address or an interface name can be
# specified - the only way to specify IPv6 interfaces is by name.
# For ibm-policyAction objects, this attribute specifies a set of
# Sysplex Distributor routing interfaces (up to 32). These routing interfaces
# are used by the SD routing component to choose among available servers
# in the S/390 sysplex. An interface value of 0 can be specified to indicate
# that the SD router can use any available target server if none of the

```

```

# target servers identified with instances of this attribute are available.
# Only IPv4 addresses can be specified.
# The default is no policy control of Sysplex Distributor routing.
# The format of this attribute is as follows:
#   ibm-interface:1- [<In-Interface-IPv4Address> ][-<Out-Interface-IPv4Address>]
#   ibm-interface:3- [<In-Interface-Name> ][-<Out-Interface-Name>]
#   Type 1 is used for IPv4 addresses for ibm-PolicyRule and
#   ibm-PolicyAction.
#   Type 3 is used for IPv4 or IPv6 names for ibm-PolicyRule.
#   If either one of the inbound/outbound interfaces is not specified,
#   all inbound/outbound interfaces are assumed. For ibm-PolicyAction
#   objects, only the outbound interface can be specified.
# This is a multi-valued attribute. However, it is treated as
# single-valued for ibm-policyRule objects by the S/390 implementation.
# some examples:
#   ibm-interface:1-9.87.65.43-9.87.60.1
#       with this specification, the corresponding rule is
#       to be applied when traffic enters interface 9.87.65.43
#       and departs on interface 9.87.60.1. As mentioned above,
#       with S/390 implementation as a server, this
#       corresponding rule WILL NOT be mapped.
#   ibm-interface:3-ETH1          no outbound specified

# ibm-idsAttackType attribute specifies the known types of intrusion
# attacks to be evaluated in conjunction with a policy rule. Attacks
# are specified as follows:
#   MALFORMED_PACKET - specifies a rule for a number of specific
#       malformed packets that are detected on inbound traffic.
#   FLOOD - specifies a rule for flooding attacks.
#   OUTBOUND_RAW - specifies a rule to enforce restrictions on the use
#       of RAW sockets for outbound processing, to prevent this stack
#       from being used to attack other systems. A list of restricted
#       IP protocols may also be specified in the rule's conditions.
#   ICMP_REDIRECT - specifies a rule for ICMP redirect detection.
#   PERPETUAL_ECHO - specifies a rule for preventing perpetual echos
#       over UDP ports. A list of local UDP ports that always respond
#       to an input packet is also specified in the rule's conditions,
#       and a separate list of remote (network) UDP ports that always
#       respond is specified. Use of this attack type is restricted to
#       using the CNF condition type, with exactly 3 CNF levels. One
#       level provides the attack type of PERPETUAL_ECHO, one level
#       provides the local ports, and one level provides the remote
#       ports. No other conditions may be specified in the rule.
#   IP_FRAGMENT - specifies a rule for detecting suspicious fragmented
#       packets.
#   RESTRICTED_IP_OPTIONS - specifies a rule to detect inbound IP
#       packets with IP options that are not allowed. A list of
#       restricted IP options is also specified in the rule's conditions.
#   RESTRICTED_IP_PROTOCOL - specifies a rule to detect inbound IP
#       packets with IP protocols that are not allowed. A list of
#       restricted IP protocols is also specified in the rule's
#       conditions.
# The format of this attribute is as follows:

# ibm-DiffServInProfileTokenBucket attribute specifies the maximum burst size of
# a token bucket traffic conditioner that enforces the burst of traffic
# that is mapped to the corresponding policy action by a policy rule. It is
# used together with the mean rate in generating tokens consumed by outgoing
# traffic.
# The format of this attribute is as follows:
#   ibm-DiffServInProfileTokenBucket:<an integer number in Kb>
#   Default is 100.
#   This is a single-valued attribute.
attribute      ibm-DiffServInProfileTokenBucket    cis   DSInProfTB      32
normal

# ibm-DiffServInProfileMaxPacketSize attribute specifies the maximum size of an
# IP packet being enforced by a token bucket traffic conditioner.
# Note that due to blocking in S/390, multiple packets tend to be sent
# back to back and if maximum packet size is just big enough for one packet,
# violation of the peak rate (peak rate enforcement is based on the size of
# each individual packet) will result and violated packets will be sent with
# different TOS value or dropped as a consequence. To accommodate this
# blocking, the value of this attribute should be set in multiples of the
# maximum packet size (e.g., equal to the token bucket size).
# The format of this attribute is as follows:
#   ibm-DiffServInProfileMaxPacketSize:<an integer number in Kb>
#   Default is 100.
#   This is a single-valued attribute.

normal

# ibm-DiffServOutProfileTransmittedTOSByte attribute specifies the TOS value to
# be used for out-of-profile traffic if the excess treatment specified is
# to send them as best effort.
# The format of this attribute is as follows:
#   ibm-DiffServOutProfileTransmittedTOSByte:<a string of 8 '0' and '1'>
#   Default is 0.
#   This is a single-valued attribute.
attribute      ibm-DiffServOutProfileTransmittedTOSByte  cis   DSOutProfTosB      8
normal

# ibm-DiffServExcessTrafficTreatment attribute specifies how a token bucket
# traffic conditioner should treat out-of-profile traffic. Two options
# can be specified, either Drop or BestEffort. If treatment is to send
# BestEffort, a different TOS value, if specified, will be used. If
# treatment is to Drop, depending on whether the traffic is UDP or TCP
# different mechanisms will be used to handle Drop treatment:
#   For UDP, traffic will actually be dropped.
#   For TCP, Drop treatment is simulated in that TCP congestion window is
#   cut (just as the case when a packet is dropped) immediately but the
#   violated packet will be sent. This is to avoid overhead associated
#   with retransmission processing and also to reduce the traffic
#   generated immediately without having to wait for a roundtrip time
#   (i.e., standard TCP lost detection delay). Also, TCP connections
#   that are mapped to the same policy (i.e., aggregation) will share
#   the throughput equally among them.
# The format of this attribute is as follows:
#   ibm-DiffServExcessTrafficTreatment:<Drop | BestEffort>
#   Default is BestEffort.
#   This is a single-valued attribute.

# to syslogd, or CONSOLE, to log to the system console.
# The format of this attribute is as follows:
#   ibm-idsNotification:NONE | SYSLOG | SYSLOGDETAIL | CONSOLE
#       The default is NONE.
# This attribute applies to version 3 policies.
# This is a multi-valued attribute, but NONE can't be specified with
# any other values.
#   an example:
#       ibm-idsNotification:CONSOLE
attribute      ibm-idsNotification            cis    idsNotification            32
normal

# ibm-idsStatInterval attribute specifies the interval length in minutes
# for collecting IDS statistics.
# The format of this attribute is as follows:
#   ibm-idsStatInterval:<an integer number>
#       The default is 60.
# This attribute applies to version 3 policies.
# This is a single-valued attribute.
#   an example:
#       ibm-idsStatInterval:600
attribute      ibm-idsStatInterval            cis    idsStatInterval            32
normal

# ibm-idsLoggingLevel attribute specifies the syslogd logging level for
# logging IDS information. Valid values are 0 through 7.
# The format of this attribute is as follows:
#   ibm-idsStatInterval:<an integer number>
#       The default is 0.
# This attribute applies to version 3 policies.
# This is a single-valued attribute.
#   an example:
#       ibm-idsLoggingLevel:1
attribute      ibm-idsLoggingLevel            cis    idsLoggingLevel            32
normal

# ibm-idsTypeActions attribute specifies the type of actions to be taken
# for IDS events. Valid values are STATISTICS, for collecting statistics
# information only, EXCEPTSTATS, for collecting exception statistics
# only, LOG, to log IDS information according to the ibm-idsNotification
# attribute, or LIMIT, to enforce IDS Traffic Regulation limits and to
# cause detected attack packets to be dropped.
# The format of this attribute is as follows:
#   ibm-idsTypeActions:STATISTICS | EXCEPTSTATS | LOG | LIMIT
# This attribute applies to version 3 policies.
# This is a multi-valued attribute.
#   an example:
#       ibm-idsTypeActions:LOG
attribute      ibm-idsTypeActions              cis    idsTypeActions              32

```

normal

```
# ibm-idsTraceData attribute specifies the amount of information written
# to the IDS event trace. Valid values are NONE, for no tracing, HEADER
# for tracing the IP and transport headers in packets, FULL, for tracing
# entire packets, or RECORDSIZE, for tracing the amount of data specified
# with the ibm-idsTraceRecordSize attribute (this amount of data
# includes the IP and transport headers).
# The format of this attribute is as follows:
#   ibm-idsTraceData:NONE | HEADER | FULL | RECORDSIZE
#   The default is HEADER.
# This attribute applies to version 3 policies.
# This is a single-valued attribute.
#   an example:
#   ibm-idsTraceData:RECORDSIZE
attribute      ibm-idsTraceData                  cis    idsTraceData          32
normal
```

```
# ibm-idsTraceRecordSize attribute specifies the amount of packet data
# to trace, when ibm-idsTraceData:RECORDSIZE is specified.
# The format of this attribute is as follows:
#   ibm-idsTraceRecordSize:<an integer number>
#   The default is 100.
# This attribute applies to version 3 policies.
# This is a single-valued attribute.
#   an example:
#   ibm-idsTraceRecordSize:50
attribute      ibm-idsTraceRecordSize            cis    idsTraceRecordSz        32
normal
```

```
# ibm-idsMaxEventMessage attribute specifies the maximum number of event
# messages to be displayed on the console during a 5 minute period for
# an IDS attack type (e.g. MALFORMED_PACKET).
# The format of this attribute is as follows:
#   ibm-idsMaxEventMessage:<an integer number>
# This attribute applies to version 3 policies.
# This is a single-valued attribute.
#   an example:
#   ibm-idsMaxEventMessage:5
attribute      ibm-idsMaxEventMessage            cis    idsMaxEventMsg          32
normal
```

```
# ibm-idsIfcFloodPercentage attribute specifies the percentage of
# discarded packets for an interface above which an interface flood
# attack is recognized. The minimum value is 5%. The default is 10%.
# The format of this attribute is as follows:
#   ibm-idsIfcFloodPercentage:<an integer number>
# This attribute applies to version 3 policies.
# This is a single-valued attribute.
#   an example:
#   ibm-idsIfcFloodPercentage:20
attribute      ibm-idsIfcFloodPercentage         cis    idsIfcFloodPrcnt        32
normal
```

```
# ibm-idsIfcFloodMinDiscard attribute specifies the minimum number of
# discarded packets for an interface that must occur within a 1 minute
# period in order to be recognized as an interface flood attack. The
# minimum value is 100. The default is 1000.
# The format of this attribute is as follows:
#   ibm-idsIfcFloodMinDiscard:<an integer number>
# This attribute applies to version 3 policies.
# This is a single-valued attribute.
#   an example:
#   ibm-idsIfcFloodMinDiscard:500
attribute      ibm-idsIfcFloodMinDiscard         cis    idsIfcFloodMinDs        32
normal
```

```
# ibm-idsTRtcpTotalConnections attribute specifies the size of the total
# connection pool for IDS TCP Traffic Regulation functions. The maximum
# value is 65535.
# The format of this attribute is as follows:
#   ibm-idsTRtcpTotalConnections:<an integer number>
```

```

#           The default is 65535.
# This attribute applies to version 3 policies.
#   This is a single-valued attribute.
#   an example:
#       ibm-idsTRtcpTotalConnections:1000
attribute      ibm-idsTRtcpTotalConnections          cis    idsTRtcpTotConn          32
normal

# ibm-idsTRtcpPercentage attribute specifies the percentage of the total
# connections allowed with the ibm-idsTRtcpTotalConnections attribute
# that can be used by a single host. The range is 0 - 100%.
# The format of this attribute is as follows:
#   ibm-idsTRtcpPercentage:<an integer number>
#       The default is 100.
# This attribute applies to version 3 policies.
#   This is a single-valued attribute.
#   an example:
#       ibm-idsTRtcpPercentage:50
attribute      ibm-idsTRtcpPercentage                cis    idsTRtcpPercent          32
normal

# ibm-idsTRtcpLimitScope attribute specifies the scope of TCP traffic
# regulation. Valid values are PORT, meaning that traffic regulation
# parameters apply to the aggregate of all sockets bound to the target
# port, or PORT_INSTANCE, meaning that traffic regulation parameters
# apply to each socket bound to the target port individually.
# The format of this attribute is as follows:
#   ibm-idsTRtcpLimitScope:PORT | PORT_INSTANCE
#       The default is PORT_INSTANCE.
# This attribute applies to version 3 policies.
#   This is a single-valued attribute.
#   an example:
#       ibm-idsTRtcpLimitScope:PORT
attribute      ibm-idsTRtcpLimitScope                 cis    idsTRtcpLmtScope        32
normal

# ibm-idsTRudpQueueSize attribute specifies the size of the port backlog
# queue. This attribute is used to select one of a number of abstract
# queue sizes that map to internally defined limits. Valid values are
# VERY_LONG, LONG, SHORT, VERY_SHORT.
# The format of this attribute is as follows:
#   ibm-idsTRudpQueueSize:VERY_LONG | LONG | SHORT | VERY_SHORT
#       The default is VERY_LONG.
# This attribute applies to version 3 policies.
#   This is a single-valued attribute.
#   an example:
#       ibm-idsTRudpQueueSize:SHORT
attribute      ibm-idsTRudpQueueSize                  cis    idsTRudpQueueSize        32
normal

# ibm-idsFSInterval attribute specifies the interval in minutes for
# monitoring for fast scanning attacks. The maximum value is 1440.
# Only one policy rule in the set of rules for a given stack can specify
# this global scan value.
# The format of this attribute is as follows:
#   ibm-idsFSInterval:<an integer number>
#       The default is 1.
# This attribute applies to version 3 policies.
#   This is a single-valued attribute.
#   an example:
#       ibm-idsFSInterval:10
attribute      ibm-idsFSInterval                      cis    idsFSInterval            32
normal

# ibm-idsFSThreshold attribute specifies the fast scanning threshold.
# A fast scan attack is detected if more events from a single source
# are detected than specified within the interval defined with the
# ibm-idsFSInterval attribute. The maximum value is 64. Only one
# policy rule in the set of rules for a given stack can specify this
# global scan value.
# The format of this attribute is as follows:
#   ibm-idsFSThreshold:<an integer number>

```

```

#           The default is 5.
# This attribute applies to version 3 policies.
#   This is a single-valued attribute.
#   an example:
#       ibm-idsFSThreshold:9
attribute      ibm-idsFSThreshold          cis    idsFSThreshold          32
normal

# ibm-idsSSInterval attribute specifies the interval in minutes for
# monitoring for slow scanning attacks. The maximum value is 1440.
# The value specified must be greater than the value specified for the
# ibm-idsFSInterval attribute. However, a value of 0 can be specified
# to indicate that no slow scan processing should be performed. Only
# one policy rule in the set of rules for a given stack can specify
# this global scan value.
# The format of this attribute is as follows:
#   ibm-idsSSInterval:<an integer number>
#           The default is 120.
# This attribute applies to version 3 policies.
#   This is a single-valued attribute.
#   an example:
#       ibm-idsSSInterval:300
attribute      ibm-idsSSInterval          cis    idsSSInterval          32
normal

# ibm-idsSSThreshold attribute specifies the slow scanning threshold.
# A slow scan attack is detected if more events from a single source
# are detected than specified within the interval defined with the
# ibm-idsSSInterval attribute. The maximum value is 64. The value
# specified must be greater than the value specified for the
# ibm-idsFSInterval attribute. However, a value of 0 can be specified
# to indicate that no slow scan processing should be performed. Only
# one policy rule in the set of rules for a given stack can specify
# this global scan value.
# The format of this attribute is as follows:
#   ibm-idsSSThreshold:<an integer number>
#           The default is 10.
# This attribute applies to version 3 policies.
#   This is a single-valued attribute.
#   an example:
#       ibm-idsSSThreshold:25
attribute      ibm-idsSSThreshold          cis    idsSSThreshold          32
normal

# ibm-idsSensitivity attribute specifies the sensitivity of events
# monitored for fast and slow scan attack detection. Events that are
# monitored can be classified as normal, possibly suspicious, or very
# suspicious. This attribute selects which of these types of events
# should be counted for scan attack detection. Valid values are
# NONE, meaning no events are counted, HIGH, meaning all event types
# are counted, MEDIUM, meaning possibly suspicious and very suspicious
# events are counted, or LOW, meaning only very suspicious events are
# counted.
# The format of this attribute is as follows:
#   ibm-idsSensitivity:NONE | HIGH | MEDIUM | LOW
#           The default is NONE.
# This attribute applies to version 3 policies.
#   This is a single-valued attribute.
#   an example:
#       ibm-idsSensitivity:MEDIUM
attribute      ibm-idsSensitivity          cis    idsSensitivity          32
normal

# ibm-idsScanExclusion attribute specifies IP addresses and optionally
# ports that are to be excluded when monitoring for scan attacks. For
# example, responses from name servers may appear to be scan attacks,
# unless the name servers are excluded using this attribute.
# The format of this attribute is as follows:
#   ibm-idsScanExclusion:1-<RemoteIPv4Address>-<PrefixMaskLength>
#                               [-<RemoteFromPort>][-<RemoteToPort>]
#                               PrefixMaskLength is the number of unmasked
#                               leading bits. An IP packet matches the action

```

```

#                                     if its remote address unmasked bits are
#                                     identical to the unmasked bits defined.
# This attribute applies to version 3 policies.
# This is a multi-valued attribute.
# some examples:
#     ibm-idsScanExclusion:1-130.0.1.1
#     ibm-idsScanExclusion:1-130.0.2.1-100-110
#     ibm-idsScanExclusion:1-130.0.3.1-53
#     The first example shows only an IP address, the second shows
#     a port range, and the last shows only one port, no range.
attribute      ibm-idsScanExclusion          cis    idsScanExclusion          32
normal

# ibm-policyRepositoryName attribute specifies the user friendly name of
# an ibm-policyRepository object. This attribute applies to version 3
# policies.
# This is a single-valued attribute.
attribute      ibm-policyRepositoryName     cis    policyRepName          256
normal

# ibm-policySubtreesAuxContainedSet attribute provides an unordered
# set of distinguished name pointers to one or more directory subtrees
# that anchor policy-related objects. This allows a more efficient
# retrieval of policy objects from an LDAP server. This attribute
# applies to version 3 policies.
# This is a multi-valued attribute. Its value is the distinguished
# name of the referenced directory subtree.
attribute      ibm-policySubtreesAuxContainedSet  dn    policySubtreeSet      256
normal

# SubnetAddr attribute specifies the interface for which the Type of
# Service (TOS) byte mappings defined with the SetSubnetPrioTosMask
# object are to be applied. The specified value must be a valid interface
# for the stack for which this attribute applies. Either an IPv4 address
# or an interface name can be specified - the only way to specify IPv6
# interfaces is by name. The format of this attribute is as follows:
#     SubnetAddr:<IPv4Address | interface_name>
#     Default is all interfaces.
# This is a single-valued attribute.
attribute      SubnetAddr                    cis    SubnetAddr              32
normal

# SubnetTosMask attribute specifies the type of service (TOS) byte bits
# that are to be considered for mapping to outbound interface priorities
# using the SetSubnetPrioTosMask object. This attribute is required.
# The format of this attribute is as follows:
#     SubnetTosMask:<a string of 8 '0' and '1'>
# This is a single-valued attribute.
attribute      SubnetTosMask                  cis    SubnetTosMask            8
normal

# PriorityTosMapping attribute specifies type of service (TOS) byte to
# outbound interface priority mappings for the SetSubnetPrioTosMask
# object. For devices that support tagging of Virtual LAN (VLAN) frames,
# the VLAN user priority can optionally be specified. This attribute
# can be repeated for each such mapping to be defined.
# The format of this attribute is as follows:
#     PriorityTosMapping:<integer number-string of 8 '0' and '1'[-integer number]>
#     The following example shows the default values for the mapping:
#     PriorityTosMapping:1-11100000
#     PriorityTosMapping:1-11000000
#     PriorityTosMapping:1-10100000
#     PriorityTosMapping:1-10000000
#     PriorityTosMapping:2-01100000
#     PriorityTosMapping:3-01000000
#     PriorityTosMapping:4-00100000
#     PriorityTosMapping:4-00000000
#     The following example shows VLAN user priority specified:
#     PriorityTosMapping:1-11000000-3
# This is a multi-valued attribute.

        SubnetAddr,
        PriorityTosMapping,
        description

```

Appendix C. Related protocol specifications

This appendix lists the related protocol specifications (RFCs) for TCP/IP. The Internet Protocol suite is still evolving through requests for comments (RFC). New protocols are being designed and implemented by researchers and are brought to the attention of the Internet community in the form of RFCs. Some of these protocols are so useful that they become recommended protocols. That is, all future implementations for TCP/IP are recommended to implement these particular functions or protocols. These become the *de facto* standards, on which the TCP/IP protocol suite is built.

RFCs are available at <http://www.rfc-editor.org/rfc.html>.

Draft RFCs that have been implemented in this and previous Communications Server releases are listed at the end of this topic.

Many features of TCP/IP Services are based on the following RFCs:

RFC

Title and Author

RFC 652

Telnet output carriage-return disposition option D. Crocker

RFC 653

Telnet output horizontal tabstops option D. Crocker

RFC 654

Telnet output horizontal tab disposition option D. Crocker

RFC 655

Telnet output formfeed disposition option D. Crocker

RFC 657

Telnet output vertical tab disposition option D. Crocker

RFC 658

Telnet output linefeed disposition D. Crocker

RFC 698

Telnet extended ASCII option T. Mock

RFC 726

Remote Controlled Transmission and Echoing Telnet option J. Postel, D. Crocker

RFC 727

Telnet logout option M.R. Crispin

RFC 732

Telnet Data Entry Terminal option J.D. Day

RFC 733

Standard for the format of ARPA network text messages D. Crocker, J. Vittal, K.T. Pogran, D.A. Henderson

RFC 734

SUPDUP Protocol M.R. Crispin

RFC 735

Revised Telnet byte macro option D. Crocker, R.H. Gumpertz

RFC 736

Telnet SUPDUP option M.R. Crispin

RFC 749

Telnet SUPDUP—Output option B. Greenberg

RFC 765

File Transfer Protocol specification J. Postel

RFC 768

User Datagram Protocol J. Postel

RFC 779

Telnet send-location option E. Killian

RFC 791

Internet Protocol J. Postel

RFC 792

Internet Control Message Protocol J. Postel

RFC 793

Transmission Control Protocol J. Postel

RFC 820

Assigned numbers J. Postel

RFC 823

DARPA Internet gateway R. Hinden, A. Sheltzer

RFC 826

Ethernet Address Resolution Protocol: Or converting network protocol addresses to 48.bit Ethernet address for transmission on Ethernet hardware D. Plummer

RFC 854

Telnet Protocol Specification J. Postel, J. Reynolds

RFC 855

Telnet Option Specification J. Postel, J. Reynolds

RFC 856

Telnet Binary Transmission J. Postel, J. Reynolds

RFC 857

Telnet Echo Option J. Postel, J. Reynolds

RFC 858

Telnet Suppress Go Ahead Option J. Postel, J. Reynolds

RFC 859

Telnet Status Option J. Postel, J. Reynolds

RFC 860

Telnet Timing Mark Option J. Postel, J. Reynolds

RFC 861

Telnet Extended Options: List Option J. Postel, J. Reynolds

RFC 862

Echo Protocol J. Postel

RFC 863

Discard Protocol J. Postel

RFC 864

Character Generator Protocol J. Postel

RFC 865

Quote of the Day Protocol J. Postel

RFC 868

Time Protocol J. Postel, K. Harrenstien

RFC 877

Standard for the transmission of IP datagrams over public data networks J.T. Korb

RFC 883

Domain names: Implementation specification P.V. Mockapetris

RFC 1213

Management Information Base for Network Management of TCP/IP-based internets: MIB-II K. McCloghrie, M.T. Rose

RFC 1215

Convention for defining traps for use with the SNMP M. Rose

RFC 1227

SNMP MUX protocol and MIB M.T. Rose

RFC 1228

SNMP-DPI: Simple Network Management Protocol Distributed Program Interface G. Carpenter, B. Wijnen

RFC 1229

Extensions to the generic-interface MIB K. McCloghrie

RFC 1230

IEEE 802.4 Token Bus MIB K. McCloghrie, R. Fox

RFC 1231

IEEE 802.5 Token Ring MIB K. McCloghrie, R. Fox, E. Decker

RFC 1236

IP to X.121 address mapping for DDN L. Morales, P. Hasse

RFC 1256

ICMP Router Discovery Messages S. Deering, Ed.

RFC 1267

Border Gateway Protocol 3 (BGP-3) K. Lougheed, Y. Rekhter

RFC 1268

Application of the Border Gateway Protocol in the Internet Y. Rekhter, P. Gross

RFC 1269

Definitions of Managed Objects for the Border Gateway Protocol: Version 3 S. Willis, J. Burruss

RFC 1270

SNMP Communications Services F. Kastenholz, ed.

RFC 1285

FDDI Management Information Base J. Case

RFC 1315

Management Information Base for Frame Relay DTEs C. Brown, F. Baker, C. Carvalho

RFC 1321

The MD5 Message-Digest Algorithm R. Rivest

RFC 1323

TCP Extensions for High Performance V. Jacobson, R. Braden, D. Borman

RFC 1325

FYI on Questions and Answers: Answers to Commonly Asked "New Internet User" Questions G. Malkin, A. Marine

RFC 1327

Mapping between X.400 (1988)/ISO 10021 and RFC 822 S. Hardcastle-Kille

RFC 1340

Assigned Numbers J. Reynolds, J. Postel

RFC 1344

Implications of MIME for Internet Mail Gateways N. Bornstein

RFC 1349

Type of Service in the Internet Protocol Suite P. Almquist

RFC 1351

SNMP Administrative Model J. Davin, J. Galvin, K. McCloghrie

- RFC 1352**
SNMP Security Protocols J. Galvin, K. McCloghrie, J. Davin
- RFC 1353**

RFC 2992

Analysis of an Equal-Cost Multi-Path Algorithm C. Hopps

RFC 3019

IP Version 6 Management Information Base for The Multicast Listener Discovery Protocol B. Haberman, R. Worzella

RFC 3060

Policy Core Information Model—Version 1 Specification B. Moore, E. Ellessen, J. Strassner, A. Westerinen

RFC 3152

Delegation of IP6.ARPA R. Bush

RFC 3164

The BSD Syslog Protocol C. Lonvick

RFC 3207

SMTP Service Extension for Secure SMTP over Transport Layer Security P. Hoffman

RFC 3226

DNSSEC and IPv6 A6 aware server/resolver message size requirements O. Gudmundsson

RFC 3291

Textual Conventions for Internet Network Addresses M. Daniele, B. Haberman, S. Routhier, J. Schoenwaelder

RFC 3363

Representing Internet Protocol version 6 (IPv6) Addresses in the Domain Name System R. Bush, A. Durand, B. Fink, O. Gudmundsson, T. Hain

RFC 3376

Internet Group Management Protocol, Version 3 B. Cain, S. Deering, I. Kouvelas, B. Fenner, A. Thyagarajan

RFC 3390

Increasing TCP's Initial Window M. Allman, S. Floyd, C. Partridge

RFC 3410

Introduction and Applicability Statements for Internet-Standard Management Framework J. Case, R. Mundy, D. Partain, B. Stewart

RFC 3411

An Architecture for Describing Simple Network Management Protocol (SNMP) Management Frameworks D. Harrington, R. Presuhn, B. Wijnen

RFC 3412

Message Processing and Dispatching for the Simple Network Management Protocol (SNMP) J. Case, D. Harrington, R. Presuhn, B. Wijnen

RFC 3413

Simple Network Management Protocol (SNMP) Applications D. Levi, P. Meyer, B. Stewart

RFC 3414

User-based Security Model (USM) for version 3 of the Simple Network Management Protocol (SNMPv3) U. Blumenthal, B. Wijnen

RFC 3415

View-based Access Control Model (VACM) for the Simple Network Management Protocol (SNMP) B. Wijnen, R. Presuhn, K. McCloghrie

RFC 3416

Version 2 of the Protocol Operations for the Simple Network Management Protocol (SNMP) R. Presuhn, J. Case, K. McCloghrie, M. Rose, S. Waldbusser

RFC 3417

Transport Mappings for the Simple Network Management Protocol (SNMP) R. Presuhn, J. Case, K. McCloghrie, M. Rose, S. Waldbusser

RFC 3418

Management Information Base (MIB) for the Simple Network Management Protocol (SNMP) R. Presuhn, J. Case, K. McCloghrie, M. Rose, S. Waldbusser

RFC 3419

Textual Conventions for Transport Addresses M. Daniele, J. Schoenwaelder

RFC 3484

Default Address Selection for Internet Protocol version 6 (IPv6) R. Draves

RFC 3493

Basic Socket Interface Extensions for IPv6 R. Gilligan, S. Thomson, J. Bound, J. McCann, W. Stevens

RFC 3513

Internet Protocol Version 6 (IPv6) Addressing Architecture R. Hinden, S. Deering

RFC 3526

More Modular Exponential (MODP) Diffie-Hellman groups for Internet Key Exchange (IKE) T. Kivinen, M. Kojo

RFC 3542

Advanced Sockets Application Programming Interface (API) for IPv6 W. Richard Stevens, M. Thomas, E. Nordmark, T. Jinmei

RFC 3566

The AES-XCBC-MAC-96 Algorithm and Its Use With IPsec S. Frankel, H. Herbert

RFC 3569

An Overview of Source-Specific Multicast (SSM) S. Bhattacharyya, Ed.

RFC 3584

Coexistence between Version 1, Version 2, and Version 3 of the Internet-standard Network Management Framework R. Frye, D. Levi, S. Routhier, B. Wijnen

RFC 3602

The AES-CBC Cipher Algorithm and Its Use with IPsec S. Frankel, R. Glenn, S. Kelly

RFC 3629

UTF-8, a transformation format of ISO 10646 R. Kermode, C. Vicisano

RFC 3658

Delegation Signer (DS) Resource Record (RR) O. Gudmundsson

RFC 3678

Socket Interface Extensions for Multicast Source Filters D. Thaler, B. Fenner, B. Quinn

RFC 3715

IPsec-Network Address Translation (NAT) Compatibility Requirements B. Aboba, W. Dixon

RFC 3810

Multicast Listener Discovery Version 2 (MLDv2) for IPv6 R. Vida, Ed., L. Costa, Ed.

RFC 3826

The Advanced Encryption Standard (AES) Cipher Algorithm in the SNMP User-based Security Model U. Blumenthal, F. Maino, K. McCloghrie.

RFC 3947

Negotiation of NAT-Traversal in the IKE T. Kivinen, B. Swander, A. Huttunen, V. Volpe

RFC 3948

UDP Encapsulation of IPsec ESP Packets A. Huttunen, B. Swander, V. Volpe, L. DiBurro, M. Stenberg

RFC 4001

Textual Conventions for Internet Network Addresses M. Daniele, B. Haberman, S. Routhier, J. Schoenwaelder

RFC 4007

IPv6 Scoped Address Architecture S. Deering, B. Haberman, T. Jinmei, E. Nordmark, B. Zill

- RFC 4022**
Management Information Base for the Transmission Control Protocol (TCP) R. Raghunarayan
- RFC 4106**
The Use of Galois/Counter Mode (GCM) in IPsec Encapsulating Security Payload (ESP) J. Viega, D. McGrew
- RFC 4109**
Algorithms for Internet Key Exchange version 1 (IKEv1) P. Hoffman
- RFC 4113**
Management Information Base for the User Datagram Protocol (UDP) B. Fenner, J. Flick
- RFC 4191**
Default Router Preferences and More-Specific Routes R. Draves, D. Thaler
- RFC 4217**
Securing FTP with TLS P. Ford-Hutchinson
- RFC 4292**
IP Forwarding Table MIB B. Haberman
- RFC 4293**
Management Information Base for the Internet Protocol (IP) S. Routhier
- RFC 4301**
Security Architecture for the Internet Protocol S. Kent, K. Seo
- RFC 4302**
IP Authentication Header S. Kent
- RFC 4303**
IP Encapsulating Security Payload (ESP) S. Kent
- RFC 4304**
Extended Sequence Number (ESN) Addendum to IPsec Domain of Interpretation (DOI) for Internet Security Association and Key Management Protocol (ISAKMP) S. Kent

Authentication/Confidentiality for OSPFv3 M. Gupta, N. Melam
- RFC 4678**
Server/Application State Protocol v1 A. Bivens
- RFC 4753**
ECP Groups for IKE and IKEv2 D. Fu, J. Solinas
- RFC 4754**
IKE and IKEv2 Authentication Using the Elliptic Curve Digital Signature Algorithm (ECDSA) D. Fu, J. Solinas
- RFC 4809**
Requirements for an IPsec Certificate Management Profile C. Bonatti, Ed., S. Turner, Ed., G. Lebovitz, Ed.
- RFC 4835**
Cryptographic Algorithm Implementation Requirements for Encapsulating Security Payload (ESP) and Authentication Header (AH) V. Manral

RFC 4862

IPv6 Stateless Address Autoconfiguration S. Thomson, T. Narten, T. Jinmei

RFC 4868

Using HMAC-SHA-256, HMAC-SHA-384, and HMAC-SHA-512 with IPsec S. Kelly, S. Frankel

RFC 4869

Suite B Cryptographic Suites for IPsec L. Law, J. Solinas

RFC 4941

Privacy Extensions for Stateless Address Autoconfiguration in IPv6 T. Narten, R. Draves, S. Krishnan

RFC 4945

The Internet IP Security PKI Profile of IKEv1/ISAKMP, IKEv2, and PKIX B. Korver

RFC 5014

IPv6 Socket API for Source Address Selection E. Nordmark, S. Chakrabarti, J. Laganier

RFC 5095

Deprecation of Type 0 Routing Headers in IPv6 J. Abley, P. Savola, G. Neville-Neil

RFC 5175

IPv6 Router Advertisement Flags Option B. Haberman, Ed., R. Hinden

RFC 5282

Using Authenticated Encryption Algorithms with the Encrypted Payload of the Internet Key Exchange version 2 (IKEv2) Protocol D. Black, D. McGrew

RFC 5996

Internet Key Exchange Protocol Version 2 (IKEv2) C. Kaufman, P. Hoffman, Y. Nir, P. Eronen

RFC 7627

Transport Layer Security (TLS) Session Hash and Extended Master Secret Extension K. Bhargavan, A. Delignat-Lavaud, A. Pironti, Inria Paris-Rocquencourt, A. Langley, M. Ray

RFC 8446

The Transport Layer Security (TLS) Protocol Version 1.3 E. Rescorla

Internet drafts

Internet drafts are working documents of the Internet Engineering Task Force (IETF), its areas, and its working groups. Other groups can also distribute working documents as Internet drafts. You can see Internet drafts at <http://www.ietf.org/ID.html>.

Appendix D. Accessibility

Accessible publications for this product are offered through [IBM Documentation for z/OS](#).

If you experience difficulty with the accessibility of any z/OS documentation see [How to Send Feedback to IBM](#) to leave documentation feedback.

Notices

This information was developed for products and services that are offered in the USA or elsewhere.

IBM may not offer the products, services, or features discussed in this document in other countries. Consult your local IBM representative for information on the products and services currently available in your area. Any reference to an IBM product, program, or service is not intended to state or imply that only that IBM product, program, or service may be used. Any functionally equivalent product, program, or service that does not infringe any IBM intellectual property right may be used instead. However, it is the user's responsibility to evaluate and verify the operation of any non-IBM product, program, or service.

IBM may have patents or pending patent applications covering subject matter described in this document. The furnishing of this document does not grant you any license to these patents. You can send license inquiries, in writing, to:

IBM Director of Licensing IBM Corporation North Castle Drive, MD-NC119 Armonk, NY 10504-1785 United States of America

For license inquiries regarding double-byte character set (DBCS) information, contact the IBM Intellectual Property Department in your country or send inquiries, in writing, to:

Intellectual Property Licensing Legal and Intellectual Property Law IBM Japan Ltd. 19-21, Nihonbashi-Hakozakicho, Chuo-ku Tokyo 103-8510, Japan

The following paragraph does not apply to the United Kingdom or any other country where such provisions are inconsistent with local law: INTERNATIONAL BUSINESS MACHINES CORPORATION PROVIDES THIS PUBLICATION "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESS OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF NON-INFRINGEMENT, MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. Some states do not allow disclaimer of express or implied warranties in certain transactions, therefore, this statement may not apply to you.

This information could include technical inaccuracies or typographical errors. Changes are periodically made to the information herein; these changes will be incorporated in new editions of the publication. IBM may make improvements and/or changes in the product(s) and/or the program(s) described in this publication at any time without notice.

This information could include missing, incorrect, or broken hyperlinks. Hyperlinks are maintained in only the HTML plug-in output for the IBM Documentation. Use of hyperlinks in other output formats of this information is at your own risk.

Any references in this information to non-IBM websites are provided for convenience only and do not in any manner serve as an endorsement of those websites. The materials at those websites are not part of the materials for this IBM product and use of those websites is at your own risk.

IBM may use or distribute any of the information you supply in any way it believes appropriate without incurring any obligation to you.

Licensees of this program who wish to have information about it for the purpose of enabling: (i) the exchange of information between independently created programs and other programs (including this one) and (ii) the mutual use of the information which has been exchanged, should contact:

IBM Corporation Site Counsel 2455 South Road Poughkeepsie, NY 12601-5400 USA

Such information may be available, subject to appropriate terms and conditions, including in some cases, payment of a fee.

The licensed program described in this document and all licensed material available for it are provided by IBM under terms of the IBM Customer Agreement, IBM International Program License Agreement or any equivalent agreement between us.

Any performance data contained herein was determined in a controlled environment. Therefore, the results obtained in other operating environments may vary significantly. Some measurements may have been made on development-level systems and there is no guarantee that these measurements will be the same on generally available systems. Furthermore, some measurements may have been estimated through extrapolation. Actual results may vary. Users of this document should verify the applicable data for their specific environment.

Information concerning non-IBM products was obtained from the suppliers of those products, their published announcements or other publicly available sources. IBM has not tested those products and cannot confirm the accuracy of performance, compatibility or any other claims related to non-IBM products. Questions on the capabilities of non-IBM products should be addressed to the suppliers of those products.

All statements regarding IBM's future direction or intent are subject to change or withdrawal without notice, and represent goals and objectives only.

This information contains examples of data and reports used in daily business operations. To illustrate them as completely as possible, the examples include the names of individuals, companies, brands, and products. All of these names are fictitious and any similarity to the names and addresses used by an actual business enterprise is entirely coincidental.

COPYRIGHT LICENSE:

This information contains sample application programs in source language, which illustrate programming techniques on various operating platforms. You may copy, modify, and distribute these sample programs in any form without payment to IBM, for the purposes of developing, using, marketing or distributing application programs conforming to the application programming interface for the operating platform for which the sample programs are written. These examples have not been thoroughly tested under all conditions. IBM, therefore, cannot guarantee or imply reliability, serviceability, or function of these programs. The sample programs are provided "AS IS", without warranty of any kind. IBM shall not be liable for any damages arising out of your use of the sample programs.

Terms and conditions for product documentation

Permissions for the use of these publications are granted subject to the following terms and conditions.

Applicability

These terms and conditions are in addition to any terms of use for the IBM website.

Personal use

You may reproduce these publications for your personal, noncommercial use provided that all proprietary notices are preserved. You may not distribute, display or make derivative work of these publications, or any portion thereof, without the express consent of IBM.

Commercial use

You may reproduce, distribute and display these publications solely within your enterprise provided that all proprietary notices are preserved. You may not make derivative works of these publications, or reproduce, distribute or display these publications or any portion thereof outside your enterprise, without the express consent of IBM.

Rights

Except as expressly granted in this permission, no other permissions, licenses or rights are granted, either express or implied, to the publications or any information, data, software or other intellectual property contained therein.

IBM reserves the right to withdraw the permissions granted herein whenever, in its discretion, the use of the publications is detrimental to its interest or, as determined by IBM, the above instructions are not being properly followed.

You may not download, export or re-export this information except in full compliance with all applicable laws and regulations, including all United States export laws and regulations.

IBM MAKES NO GUARANTEE ABOUT THE CONTENT OF THESE PUBLICATIONS. THE PUBLICATIONS ARE PROVIDED "AS-IS" AND WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING BUT NOT LIMITED TO IMPLIED WARRANTIES OF MERCHANTABILITY, NON-INFRINGEMENT, AND FITNESS FOR A PARTICULAR PURPOSE.

IBM Online Privacy Statement

IBM Software products, including software as a service solutions, ("Software Offerings") may use cookies or other technologies to collect product usage information, to help improve the end user experience, to tailor interactions with the end user, or for other purposes. In many cases no personally identifiable information is collected by the Software Offerings. Some of our Software Offerings can help enable you to collect personally identifiable information. If this Software Offering uses cookies to collect personally identifiable information, specific information about this offering's use of cookies is set forth below.

Depending upon the configurations deployed, this Software Offering may use session cookies that collect each user's name, email address, phone number, or other personally identifiable information for purposes of enhanced user usability and single sign-on configuration. These cookies can be disabled, but disabling them will also eliminate the functionality they enable.

If the configurations deployed for this Software Offering provide you as customer the ability to collect personally identifiable information from end users via cookies and other technologies, you should seek your own legal advice about any laws applicable to such data collection, including any requirements for notice and consent.

For more information about the use of various technologies, including cookies, for these purposes, see IBM's Privacy Policy at ibm.com/privacy and IBM's Online Privacy Statement at ibm.com/privacy/details in the section entitled "Cookies, Web Beacons and Other Technologies," and the "IBM Software Products and Software-as-a-Service Privacy Statement" at ibm.com/software/info/product-privacy.

Policy for unsupported hardware

Various z/OS elements, such as DFSMS, JES2, JES3, and MVS, contain code that supports specific hardware servers or devices. In some cases, this device-related element support remains in the product even after the hardware devices pass their announced End of Service date. z/OS may continue to service element code; however, it will not provide service related to unsupported hardware devices. Software problems related to these devices will not be accepted for service, and current service activity will cease if a problem is determined to be associated with out-of-support devices. In such cases, fixes will not be issued.

Minimum supported hardware

The minimum supported hardware for z/OS releases identified in z/OS announcements can subsequently change when service for particular servers or devices is withdrawn. Likewise, the levels of other software products supported on a particular release of z/OS are subject to the service support lifecycle of those products. Therefore, z/OS and its product publications (for example, panels, samples, messages, and product documentation) can include references to hardware and software that is no longer supported.

- For information about software support lifecycle, see: [IBM Lifecycle Support for z/OS \(www.ibm.com/software/support/systemsz/lifecycle\)](http://www.ibm.com/software/support/systemsz/lifecycle)
- For information about currently-supported IBM hardware, contact your IBM representative.

Policy for unsupported hardware

Various z/OS elements, such as DFSMS, HCD, JES2, JES3, and MVS, contain code that supports specific hardware servers or devices. In some cases, this device-related element support remains in the product even after the hardware devices pass their announced End of Service date. z/OS may continue to service element code; however, it will not provide service related to unsupported hardware devices. Software problems related to these devices will not be accepted for service, and current service activity will cease if a problem is determined to be associated with out-of-support devices. In such cases, fixes will not be issued.

Trademarks

IBM, the IBM logo, and ibm.com are trademarks or registered trademarks of International Business Machines Corp., registered in many jurisdictions worldwide. Other product and service names might be trademarks of IBM or other companies. A current list of IBM trademarks is available on the web at [Copyright and trademark information at www.ibm.com/legal/copytrade.shtml](http://www.ibm.com/legal/copytrade.shtml).

Bibliography

This bibliography contains descriptions of the documents in the z/OS Communications Server library.

z/OS Communications Server documentation is available online at the z/OS Internet Library web page at <http://www.ibm.com/systems/z/os/zos/library/bkserv/>.

z/OS Communications Server library updates

Updates to documents are also available on RETAIN and in information APARs (info APARs). Go to <https://www.ibm.com/mysupport> to view information APARs.

z/OS Communications Server information

z/OS Communications Server product information is grouped by task in the following tables.

Planning

Title	Number	Description
z/OS Communications Server: New Function Summary	GC27-3664	This document is intended to help you plan for new IP or SNA functions, whether you are migrating from a previous version or installing z/OS for the first time. It summarizes what is new in the release and identifies the suggested and required modifications needed to use the enhanced functions.
z/OS Communications Server: IPv6 Network and Appl Design Guide	SC27-3663	This document is a high-level introduction to IPv6. It describes concepts of z/OS Communications Server's support of IPv6, coexistence with IPv4, and migration issues.

Resource definition, configuration, and tuning

Title	Number	Description
z/OS Communications Server: IP Configuration Guide	SC27-3650	This document describes the major concepts involved in understanding and configuring an IP network. Familiarity with the z/OS operating system, IP protocols, z/OS UNIX System Services, and IBM Time Sharing Option (TSO) is recommended. Use this document with the z/OS Communications Server: IP Configuration Reference .

Title	Number	Description
z/OS Communications Server: IP Configuration Reference	SC27-3651	This document presents information for people who want to administer and maintain IP. Use this document with the z/OS Communications Server: IP Configuration Guide . The information in this document includes: <ul style="list-style-type: none"> • TCP/IP configuration data sets • Configuration statements • Translation tables • Protocol number and port assignments
z/OS Communications Server: SNA Network Implementation Guide	SC27-3672	This document presents the major concepts involved in implementing an SNA network. Use this document with the z/OS Communications Server: SNA Resource Definition Reference .
z/OS Communications Server: SNA Resource Definition Reference	SC27-3675	This document describes each SNA definition statement, start option, and macroinstruction for user tables. It also describes NCP definition statements that affect SNA. Use this document with the z/OS Communications Server: SNA Network Implementation Guide .
z/OS Communications Server: SNA Resource Definition Samples	SC27-3676	This document contains sample definitions to help you implement SNA functions in your networks, and includes sample major node definitions.
z/OS Communications Server: IP Network Print Facility	SC27-3658	This document is for systems programmers and network administrators who need to prepare their network to route SNA, JES2, or JES3 printer output to remote printers using TCP/IP Services.

Operation

Title	Number	Description
z/OS Communications Server: IP User's Guide and Commands	SC27-3662	This document describes how to use TCP/IP applications. It contains requests with which a user can log on to a remote host using Telnet, transfer data sets using FTP, send electronic mail, print on remote printers, and authenticate network users.
z/OS Communications Server: IP System Administrator's Commands	SC27-3661	This document describes the functions and commands helpful in configuring or monitoring your system. It contains system administrator's commands, such as TSO NETSTAT, PING, TRACERTE and their UNIX counterparts. It also includes TSO and MVS commands commonly used during the IP configuration process.
z/OS Communications Server: SNA Operation	SC27-3673	This document serves as a reference for programmers and operators requiring detailed information about specific operator commands.
z/OS Communications Server: Quick Reference	SC27-3665	This document contains essential information about SNA and IP commands.

Customization

Title	Number	Description
z/OS Communications Server: SNA Customization	SC27-3666	<p>This document enables you to customize SNA, and includes the following information:</p> <ul style="list-style-type: none"> • Communication network management (CNM) routing table • Logon-interpret routine requirements • Logon manager installation-wide exit routine for the CLU search exit • TSO/SNA installation-wide exit routines • SNA installation-wide exit routines

Writing application programs

Title	Number	Description
z/OS Communications Server: IP Sockets Application Programming Interface Guide and Reference	SC27-3660	This document describes the syntax and semantics of program source code necessary to write your own application programming interface (API) into TCP/IP. You can use this interface as the communication base for writing your own client or server application. You can also use this document to adapt your existing applications to communicate with each other using sockets over TCP/IP.
z/OS Communications Server: IP CICS Sockets Guide	SC27-3649	This document is for programmers who want to set up, write application programs for, and diagnose problems with the socket interface for CICS using z/OS TCP/IP.
z/OS Communications Server: IP IMS Sockets Guide	SC27-3653	This document is for programmers who want application programs that use the IMS TCP/IP application development services provided by the TCP/IP Services of IBM.
z/OS Communications Server: IP Programmer's Guide and Reference	SC27-3659	This document describes the syntax and semantics of a set of high-level application functions that you can use to program your own applications in a TCP/IP environment. These functions provide support for application facilities, such as user authentication, distributed databases, distributed processing, network management, and device sharing. Familiarity with the z/OS operating system, TCP/IP protocols, and IBM Time Sharing Option (TSO) is recommended.
z/OS Communications Server: SNA Programming	SC27-3674	This document describes how to use SNA macroinstructions to send data to and receive data from (1) a terminal in either the same or a different domain, or (2) another application program in either the same or a different domain.
z/OS Communications Server: SNA Programmer's LU 6.2 Guide	SC27-3669	This document describes how to use the SNA LU 6.2 application programming interface for host application programs. This document applies to programs that use only LU 6.2 sessions or that use LU 6.2 sessions along with other session types. (Only LU 6.2 sessions are covered in this document.)
z/OS Communications Server: SNA Programmer's LU 6.2 Reference	SC27-3670	This document provides reference material for the SNA LU 6.2 programming interface for host application programs.

Title	Number	Description
z/OS Communications Server: CSM Guide	SC27-3647	This document describes how applications use the communications storage manager.

Diagnosis

Title	Number	Description
z/OS Communications Server: IP Diagnosis Guide	GC27-3652	This document explains how to diagnose TCP/IP problems and how to determine whether a specific problem is in the TCP/IP product code. It explains how to gather information for and describe problems to the IBM Software Support Center.
z/OS Communications Server: ACF/TAP Trace Analysis Handbook	GC27-3645	This document explains how to gather the trace data that is collected and stored in the host processor. It also explains how to use the Advanced Communications Function/Trace Analysis Program (ACF/TAP) service aid to produce reports for analyzing the trace data information.
z/OS Communications Server: SNA Diagnosis Vol 1, Techniques and Procedures and z/OS Communications Server: SNA Diagnosis Vol 2, FFST Dumps and the VIT	GC27-3667 GC27-3668	These documents help you identify an SNA problem, classify it, and collect information about it before you call the IBM Support Center. The information collected includes traces, dumps, and other problem documentation.
z/OS Communications Server: SNA Data Areas Volume 1 and z/OS Communications Server: SNA Data Areas Volume 2	GC31-6852 GC31-6853	These documents describe SNA data areas and can be used to read an SNA dump. They are intended for IBM programming service representatives and customer personnel who are diagnosing problems with SNA.

Messages and codes

Title	Number	Description
z/OS Communications Server: SNA Messages	SC27-3671	This document describes the ELM, IKT, IST, IUT, IVT, and USS messages. Other information in this document includes: <ul style="list-style-type: none"> • Command and RU types in SNA messages • Node and ID types in SNA messages • Supplemental message-related information
z/OS Communications Server: IP Messages Volume 1 (EZA)	SC27-3654	This volume contains TCP/IP messages beginning with EZA.
z/OS Communications Server: IP Messages Volume 2 (EZB, EZD)	SC27-3655	This volume contains TCP/IP messages beginning with EZB or EZD.
z/OS Communications Server: IP Messages Volume 3 (EZY)	SC27-3656	This volume contains TCP/IP messages beginning with EZY.
z/OS Communications Server: IP Messages Volume 4 (EZZ, SNM)	SC27-3657	This volume contains TCP/IP messages beginning with EZZ and SNM.
z/OS Communications Server: IP and SNA Codes	SC27-3648	This document describes codes and other information that appear in z/OS Communications Server messages.
